The first really hopeful sign that the High Chinese Authorities are alive to the serious depression that has for years overhung the Tea Trade of China and that there are at last some among them who have a true perception of the only real means to remedy the evils producing that depression, comes from Formosa. There the energetic and able Governor Liu Ming Chuan has granted to an enterprising merchant, Mr. F. Cass, the necessary permission to establish a model tea plantation and factory where tea will be grown, cultivated, prepared and packed after the Indian method and by the aid of the very best mechanical appliances. To this farm a school will be attached for the requisite training of a number of youths, selected to be tea planters in various parts. We most heartily congratulate Mr. Cass, his Chinese partner (who owns, we understand, the largest tea plantations in the island), and also His Excellency Governor Liu on their undertaking, to which we cordially wish every success. That Governor Liu should have the shrewdness and courage to inaugurate a practical attempt to reform and save the Formosan tea trade while it is yet time, is but another indication that in all his undertakings he holds steadily in view not only the governmental interests but also the prosperity of the people. The trade in Formosan tea has hitherto held its own fairly well against the competing Japanese tea, but there have not been wanting indications, especially during the past season, that the same reckless over-production, careless preparation and fraudulent adulteration with dust and broken leaves, which have done so much harm at other Chinese tea centres, exist here. Add to this the fact that the tea-planters, after putting in their shrubs, trust entirely to the original native richness of the virgin soil, and never attempt to manure and prune the plants or hoe the ground and it is no difficult matter to account for the impoverished soil and consequent serious deterioration of the tea, which has resulted in the almost total disappearance from the market of the finer and choicer qualities. It is mainly this defective cultivation, combined with over-production, which is responsible for the present state of the tea trade in China. The question of taxation is altogether a secondary consideration. At present, whilst every petty peasant can grow and find a market for his few cattiees of leaves grown on the stunted and feeble bushes planted near his door, it is useless to talk of lectures, pamphlets etc. or even proclamations as likely to limit the production within reasonable bounds or to meet in a practical manner the evils which threaten to result in the elimination of the tea trade of China. For 'spose can catchee channee what for no make bye and bye,' is the general idea of the petty producer. The true method of reform lies in the line of the experiments made in Formosa. The establishment of model estates on a large scale by raising the standard of quality ought to prove practically to the larger tea planters the advantages of Indian methods, and will, if it is to be hoped, induce them to combine and make large plantations. Mr. Cass and his partner have engaged a high class practical man in India, who is now on his way to Formosa. On arrival he will select a site, prepare the soil, plant and cultivate the plants and also superintend the picking, withering, rolling, firing and packing of the tea. The whole process will be carried out on the estate, and the aid of the best mechanical appliances will be obtained. The promoters of this enterprise and the Governor hope that by this means a high standard of quality will be arrived at and maintained, and that the other tea merchants, seeing the practical advantages of the system, will avail themselves of the facilities afforded for acquiring the requisite technical knowledge, and be induced to establish similar estates for the scientific cultivation and careful preparation of tea and also to introduce the simple machinery thereto necessary. If this should happen, and it is devoutly to be hoped it will, the trouble of over-

production will disappear,* and the trade of Formosa will be placed on so sound a basis that competition need not be feared but rather welcomed as a keen incentive to further efforts. Should no brilliant success at once attend this new departure, much good is certain to be the outcome of it in the end, and Mr. Cass will have the pleasure of being the pioneer of a plan by which a new lease of life will be given to the Formosa Tea Trade. H. E. Governor Liu deserves great credit for his sagacious act, and still more for the pluck he has displayed in attempting to solve the problem of how to save the tea trade of his Island; while his experiments, if successful, may lead to the salvation of that trade throughout the Empire. India, Ceylon and Japan had better look to themselves, for a few more such men as Liu Ming Chuan in China would speedily settle the question of the supremacy of China leaf over its rivals. The trade, aided instead of thwarted by high officials, will show an amount of vitality that will surprise the competitors. All those who have the best interests of China at heart must sincerely wish prosperity to attend this enterprise and hope that other high officials may be found with wisdom enough to follow the example set by Liu Ming Chuan.—*China Mail*, Dec. 13th.

[There can be little doubt of Formosa producing the finest tea in the world, but our late-est intelligence is that of a serious rebellion of the aborigines against the Chinese.—Ed. T. A.]

SZ-CHUAN TEA.

In Western China is the province of Sz-Chuan, noted for supporting a population estimated from 35,000,000 to 70,000,000, the Catholic missionaries placing it at 45,000,000. It is a mountainous district, where the winters are very mild, white frost seldom seen, and snow almost unknown. This province, seldom visited by white men, has nearly 200,000 square miles within its borders. Here one finds native tribes under their own chiefs. As it is one of the tea districts of China about which little is known, we avail ourselves of a description of a journey to Western China by an English clergyman, who states that in the great variety of its productions it excels all other provinces. There is scarcely an article grown in China which is not found here in great abundance. Rice is a staple product, and in good years the ample supply allows it to be exported to the East. Wheat is grown everywhere, and is of the best quality; barely, peas, Indian corn and millet grow in vast quantities. Sugar-cane and sorghum are produced in sufficient abundance for home consumption, and some cotton is grown. It produces more silk than any other province, as well as hemp in large quantities. It raises the best tobacco, and, in recent years, large quantities of opium. It has an ample supply of oranges, lemons, pumalos, peaches, apples, pears, plums, cherries and other small fruits. Of medicines it produces enough for half the empire, and exports great quantities. Its salt-wells are celebrated all over China, and their products find their way to several contiguous provinces, and to the table-lands of Central Asia.

The soil and climate are well adapted to tea culture, of which a considerable amount is now exported. There is much tea exported to Siberia via Si-ngan-foo. Besides the ordinary tea, which is extensively cultivated for home and foreign consumption, there are two kinds of tea on Mount Omei which are peculiar to that mountain, and sold largely to pilgrims, called "sweet tea" and "white tea." The sweet tea is made from the leaves of a slender growing shrub which is found half way to the top of the mountain. The leaf is large and thick, and when green has no sweetness; but when dried it has a peculiar, sweet, licorice-like flavor not altogether unpleasant. The white tea is prepared from the leaf of a very peculiar shrub found upon the side of the mountain; it is palatable, and not unlike the genuine tea of commerce in flavor.

Besides these teas, which are never exported, except in small quantities by visitors, there are two kinds of very good tea, grown by the priests and farmers around the monasteries. The tea-shrubs were not unlike those found in abundance in Kiangsi, and the tea is quite as good as that grown in Nganhui.

Thibet and the wild tribes are furnished with tea from the provinces, principally from Kiungcheu. Abbé Huo says "You meet every moment on these narrow paths long files of porters carrying brick tea, which is prepared at Khiong-Teheou, and forwarded from Tatsien-lu to the different provinces of Thibet. Brick tea and the *khata*, or scarf of felicity," are the great articles of trade between China and Thibet. It is scarcely credible what a prodigious quantity of these goods is exported annually from the provinces of Kan-su and Sz-Chuan."—*American Grocer*.

THE "GROCER" ON CEYLON TEA.

In giving the separate movements of this article for the first ten months of the year, it is interesting to notice how rapidly the trade is expanding in all directions, and also how great an influence Ceylon tea is exercising upon the course of the market for other kinds, and especially that for China, which is receding into the background more and more every month. According to the latest private returns, the landings of Ceylon tea in London during October were 1,953,500 lb., against 1,691,800 lb. last year, and 815,100 lb. in 1887. These amounts, added to previous totals, make the receipts for this year equal to 25,924,800 lb. in comparison with 16,720,300 lb. in 1888, and 9,259,650 lb. in the former year, showing a most extraordinary increase in the supply. None the less astonishing are the deliveries, which for the past month embraced 2,655,500 lb., in place of 1,855,450 lb. and 1,008,950 lb., in the two preceding years, thus bringing the total clearances for the present year up to the 31st ultimo to 26,099,800 lb., as contrasted with 15,454,900 lb. and 8,409,750 lb. in 1888 and 1887 for the same period. Seldom is it that so rapid a growth as this is seen in the use of any necessary of life, and it forces the conviction upon one's mind that the gain observable here is at the expense of another article of daily consumption, which is being more generally neglected because of a decided change in the public taste. What Ceylon tea has gained in reputation and patronage China has clearly lost; and instead of being larger, as before, both the imports and deliveries of the latter sort into London during past ten months have been strikingly smaller than in either 1887 or 1888, the difference between the respective totals being reckoned by between 20,000,000 lb. and 25,000,000 lb. in the last two seasons.

Having recognised the fact as above explained, the next thing to do is to point out the cause of these remarkable changes in the position of Ceylon and China teas, and this is traceable to the superior quality of the former as judged by consumers themselves, who have grown tired of the poor, thin-liquoring teas of China, however soft and mild their flavour may be, and have preferred the stronger, more pungent, and, as some think, much coarser kinds of Indian and Ceylon. In support of this opinion, we quote that of an eminent firm in the China tea trade, who may be depended upon for speaking in an unbiased and unprejudiced manner even upon a subject which so closely touches their own interests, when they assert that—"If we compare Indian and Ceylon growths with China teas, we can only come to the conclusion, taking the intrinsic value of the article, that the public are right; and although we hear of the wonderful teas China used to produce in the old East India Company's days, we are somewhat sceptical on that point. The teas were fine because there was no other standard to gauge them by, and as China produces at the present moment as fine Oolongs and as fine Green Teas as we have ever seen, there is no tangible reason why Black Teas should have so much deteriorated."

* A most astonishing conclusion, surely.—Ed. T. A.

Other reliable testimony could be produced to prove the truth of the foregoing remarks, which are based upon actual experience rather than upon mere theory and nearly every circumstance that comes under our notice points to the same result. But the trade are now running the risk of falling into a new danger by the threatened scarcity of common teas, through China Monings and Kaisows not arriving here in the same abundance as hitherto, and the reports from India are not so satisfactory as they were regarding the outturn of the present season's crops, most of them stating the yield to be about 5,000,000 lb. lighter than originally estimated, or not beyond 96,000,000 lb. to 100,000,000 lb. at the outside. It is however, the more gratifying to know that the production of tea in Ceylon betrays no signs of diminution; on the contrary, it progresses more favourably than ever, and is likely to reach between 42,000,000 lb. and 43,000,000 lb. in the coming year. Last season's crop yielded about 33,000,000 lb., and in 1887-88 it comprised nearly 21,000,000 lb., so that the present one is double that in 1888-89. This is an encouraging fact for the dealers and retailers, who may rely upon a further increase in the supplies of their favourite description of tea, if those from China should disappoint them; and while the public demand a particular class of tea it is the duty of the trade to serve them with the article they require, so long as circumstances render this possible.—*Grocer*.

A CINCHONA AND QUININE FACTORY IN SOUTHERN INDIA.

The Wynaad Planters' Association allude in their last annual report to a disease that is killing out young cinchona clearings wholesale in many parts of the district, and propose to address Government for the services of Mr. Lawson to investigate the matter. If it is a disease it is not novel, as the unaccountable dying off of cinchona seedlings has repeatedly occurred on the Nilgiris and the cause is veiled in mystery. We trust the Director will be able to throw some light on the subject, as from his annual reports it would appear the phenomenon is not unknown on the Government plantations. The probability of the Wynaad planters starting a quinine factory of their own, for the treatment of bark grown in the district, depends they say on the absence of competition by Government, and the richness of the bark in alkaloids. If by united effort such a factory could be established, we think that much benefit would result to the planter, the freight on a large quantity of useless material transported would be saved, and the duty on the drug be put into the grower's pocket, instead of going into the revenue. The Neddium factory should be able to furnish some idea of the cost of machinery, and if it proves successful there ought to be data available for the other question needing solution.—*South of India Observer*, 4th Jan. 1890.

THE SEASON IN INDIA.

The weekly summary of the provincial reports on the weather and prospects of the crops is as follows:—**MADRAS**.—For week ending December 28th.—Rainfall good in Godavari, Madras, Chingleput, North Arcot, Nilgeris and South Canara; none in Bellary, Kurnool, Tinnevely; slight in Kistna, Tanjore, Madura and Coimbatore, and moderate elsewhere. Crops improving after the recent rains, but withering in parts of South Arcot, Madura, Tinnevely, Coimbatore, Salem and Ellore. Prices generally falling or stationary. General prospects much improved.

BENGAL.—For week ending December 31st.—Rainfall during the week very slight, and confined to a few districts only. Rice harvest for the most part over, and the general outturn for the whole Province is expected to be average or nearly so.

BURMA.—For week ending December 28th.—There was slight rain in Bassein and Amherst in Lower Burma, and slight rain generally in all districts of Upper Burma, except Pynmana. The price of paddy

has fallen slightly in Thongwa and risen slightly in Prome; elsewhere in Lower Burma, there are no fluctuations. In Upper Burma, a fall is noticeable in Katha; elsewhere prices remain unchanged. With the exception of part of the Prome District where some crops were damaged for want of late rains, the crops throughout the Province promise well. The food supply is sufficient.—*Pioneer*, Jan. 7th.

THE BRITISH EAST AFRICAN COMPANY.

From an independent and perfectly reliable source a London correspondent hears that the British East African Company are already taking measures for the settlement of their territory. They are importing labour extensively from Persia, and the correspondent's informant recently met at one of the Indian ports a batch of the men *en route* for the East African littoral. They are described as fine, stalwart men, and splendid specimens of the Persian agriculturist. Among their impedimenta were their native implements, which, it is believed, they will find more serviceable than the more modern productions of the West. Their future is very much in the hands of the local officers of the company, but it is settled that they are to have a free grant of land and assistance in other ways, and it is probable that they will devote themselves to the cultivation of tobacco and opium, for which the soil of East Africa is admirably adapted.—*P. M. Budget*.

PLANTING IN DELI: SUGAR AND TOBACCO.

(From the *Straits Times*, Jan. 7th.)

The *Delhi Courant* learns, on good authority, that the Netherlands India Government intends to liberalise the land laws in its outlying possessions. The object is to give the local authorities greater discretionary powers in the matter of granting waste land for settlement. Hitherto, applications of this kind have been dealt with at Batavia, where delays of office do not fail to hamper planting enterprise.

The new Coolie Ordinance shows several shortcomings which the Planters' Association have not been long in laying their fingers upon, to such purpose that its amendment will shortly be taken in hand. As the law stands, one chief defect lies in allowing coolies to leave estates in a body, unpunished, provided they turn out on the pretence of laying their real or fancied grievances before the nearest officials. Peace and order on plantations will be imperilled as soon as the coolies find this out.

The negotiations for an inflow of Tamil immigrants for estate labour in Deli have entered upon such a stage that there is every prospect of a satisfactory result. The Netherlands Indian Government has yielded the main point urged by the Indian Government in consenting to the appointment of a Protector of Tamil coolies.

Meanwhile, the Chinese coolies in the land give the planters trouble enough. The Simpang Tiga, Sunghie Silam, and Hessa Estates in Assahan have been recently scenes of disturbance. On one of them a row among the labourers narrowly led to their marching off in a body, and it took a large body of police to restore order. On another, differences about pay nearly brought on a riot. On the third, the coolies raised a disturbance which resulted in a couple of assistants being ill-treated. They then left the estate, and appeared before the nearest magistrate, to whom they behaved so threateningly that he had to overawe them by armed force. With great difficulty they were induced to return to the estate.

On the Tandem Hilir estate in Lower Langkat, a coolie riot last month reached such proportions that armed police had to intervene. They found themselves obliged to open fire on the rioters, who soon quieted down on a volley, killing six of them and wounding five more. The police, thus set at defiance, mustered

34 strong under European leadership. This incident shows how far Chinese presumption will go when they can raise the heel against authority with fancied impunity.

A still more striking example of this too place on the 22nd December, on the Amplas estate, where the coolies so went beyond bounds as to refuse to work unless three overseers were discharged. They so stiffly stood by their demands that all efforts to quiet them failed. Emboldened by the inactivity of the police on the spot, about 600 coolies set upon them with such violence that fire had to be opened on the raging multitude. Twenty-five of the latter fell, and the balance lost no time in seeking safety in flight. Most of them came back soon and quietly resumed work. They were so cowed as to offer no resistance to the arrest of 21 of their ringleaders.

In Assahan, tobacco cultivation has a splendid future before it. The *Deli Courant* of the 28th December speaks hopefully of the prospects of that line of industry there. Large areas of land have been taken up and put under crop. The tobacco produced fetches higher prices than that grown in Deli and Langkat. Last year's crop far exceeds that of 1888 both in quantity and quality. Eleven estates have been opened out with results so satisfactory that this year's crop is expected to aggregate about three millions of Amsterdam pounds. Assahan presents a favourable field for planting enterprise, owing to the soil not being so impoverished as in Deli, where fertilisers have now to be resorted to for counteracting exhaustion.

SUMATRA TOBACCO.

Amsterdam, Dec. 18th.—In one of my former letters some interesting figures were given regarding the extension of the crop of Sumatra tobacco, which was in 1865, when the first lot arrived in Amsterdam, 189 bales, representing a value of f. 40,000, against an import in 1888 of more than 182,000 bales, value of about f. 35,500,000, which fully proves the development of the cultivation and the enterprising spirit of the planters. However, some very favourable circumstances have contributed largely to this increase. The Sumatra leaf is very much liked for covers of cigars, and was soon introduced on all markets of Europe, especially in Germany and Austria. For some years Sumatra tobacco has attracted much attention for export to the United States of America, and of the 1888 crop about a quarter found buyers there which represents one-third of the value. For the American market only the large leaves are taken, which are consequently the most expensive parts of a parcel. With regard to the 1889 crop nothing can be said with certainty, although the reports indicate that the quantity will probably not be smaller than that of the preceding year, as several new undertakings will ship their tobacco in 1890 to Europe. The quality is expected to be lighter. The 1889 crop was sold, on the average, at very satisfactory prices.—*Cor., L. & C. Express*, Dec. 20.

THE MOUNTAINS OF NEW GUINEA.

Naturalists, and among them horticulturists, have been anxiously awaiting the results of explorations in the interior of New Guinea. The vegetation of the coast regions and of the banks of the rivers, so far as travellers have yet penetrated, presents comparatively few novelties, being what might be expected in an island placed in that situation; but it might fairly be anticipated that the mountain vegetation would reveal transitions between the floras of Java, Borneo, and even of the subtropical Himalaya and that of Australia. Possibly, even, some connection may yet be found between the vegetable population of the high lands of tropical Africa, of Madagascar, and of

South America, especially the Chilian and Patagonian regions and that of New Guinea. The horticulturist may fairly anticipate new types of Orchids, Ferns, Nepenthes, Rhododendrons, Cycads, Conifers, Melastomads, and other interesting families. The obstacles in the way of reaching the mountains are very considerable, the difficulties of collection hardly less so, hence the following letter from Baron Sir Ferdinand von Mueller will be read with proportionate interest, and all naturalists will agree in the hope that the chief authority on the Australian flora may be enabled to continue his already extensive researches into the botany of Papua, and weld them into a connected whole with those of Australia, and thus throw light on many of the most important problems of botanical geography. The occurrence of British genera and species on the mountains of New Guinea, though it will not appear strange to the botanist, will doubtless occasion surprise to many. We append the Baron's interesting letter:—

"The ascent of the Owen Stanley Ranges in New Guinea to their very summit, recently accomplished by Sir William Macgregor, demonstrates the occurrence of an almost alpine vegetation between elevations of 11,000 and 13,000 feet; and, more than this, it renders known for the first time an extraordinary and significant admixture of forms, some characteristic of the northern, others of the southern hemisphere. On the crest of the range above the limits of forests occur, as we now learn, though so near to the equator, such mainly extratropical genera as *Ranunculus*, *Hypericum*, *Arenaria*, *Patentia*, *Rubus*, *Epilobium*, *Aster*, *Erigeron*, *Helichrysum*, *Senecio*, *Gentiana*, *Veronica*, *Euphrasia*, *Scirpus*, *Schoenus*, *Carex*, *Agrostis*, *Aiza*, *Poa*, and *Festuca*. Many of these approach in their affinity to forms familiar to us in Europe, a few even being identical with British species, and which reach in New Guinea seemingly their most southern geographical limits. But on the other hand, many of these Papuan highland plants are of far southern type, such as *Drimys*, *Drapetes*, *Donatia*, *Styphelia*, *Phyllocladus*, *Libertia*, *Carpha*, *Dawsonia*; indeed some of the species are absolutely the same or congeneric with those of the Australian and New Zealand Alps. In the collection, which necessarily, during this first attempt at the exploration, could not be very rich in specific forms, Ericæ (of the genera *Rhododendrons*, *Agapetes*, and *Vaccinium*), are rather prominent. Another remarkable fact now established is the identity of several plants of the Owen Stanley Ranges with such as were described by Sir Joseph Hooker from Kinu-Balu, in Northern Borneo where they were discovered by Sir Hugh Low at elevations of about 8000 feet—for instance, *Drapetes ericoides* and *Drimys piperita*. The four Conifers, gathered during Sir Will. Macgregor's expedition, consist of *Araucaria Cunninghamii*, a *Podocarpus*, a *Phyllocladus*, and what may possibly be a *Libocedrus*; of the latter, however, no fruit was obtained, so far as the material before us allows to judge, the individuality in the alpine vegetation of New Guinea seems far less extensive than might have been supposed. The writer of these lines pointed out some years ago, in opposition to the views of distinguished naturalist, that, although the main characteristics of the Papuan flora in the lowlands and midlands might, notwithstanding the occurrence of Eucalypts and phyllocladaceous Acacias be regarded as Malayan, yet it would not be accurate to ascribe the same general characteristics to the highland vegetation as well, when *Araucaria* had already come within reach. The fact that the Papuan alpine flora contained so large a proportion of Australian elements, must lead to many far-reaching scientific generalisations in other departments of science besides botany."

A correspondent of the *Daily News* furnishes further particulars:—

"You will no doubt have heard by wire that at last a man has stood upon the highest point of Mount Owen Stanley, that man being the new governor, Sir W. Macgregor. He left here (Port Moresby) with a fairly large party on April 20, and

yesterday (June 25) he returned. He, three natives, and two South Sea men got to the top—over 13,000 feet—and spent three days up there, with a clear blue sky above him, a climate the best he has known, and with Daisies, Buttercups, and white Heather round him to remind him of his native land. He also heard the lark singing at the top, and saw acicles 7 inches long. The natives felt the cold terribly but the Governor never had a moment's sickness, though, when he came down, he had lost considerably in weight—he was a very heavy man when he started. The natives of the surrounding region were all very friendly, but he could not get one of them to go above 9000 feet, up to which line they sometimes hunt.”—*Gardeners' Chronicle*.

COCONUT BUTTER.

[Says a correspondent in sending us the following:—“This must be the stuff they are manufacturing at the new factory at Veyangoda—the object of which was a secret.”—Ed. .T.A.]

The trade in coconut butter, unknown a year ago, has assumed during the past few months dimensions which may fairly be described as extraordinary. The discovery that the coconut contained a nutritious fatty substance, admirably adapted as a substitute for butter was made in 1888 by a practical chemist at Ludwigshafen, near Mannheim, in the Rhine country. This chemist, Dr. Schlunk, found on analysis that the milk of these nuts contains some 60 to 70 per cent of fat, and 23 to 25 per cent of organic substances, of which nine or ten per cent is albumen. Liebig had long before this discovered the value of coconut oil or fat, but did not succeed in getting from it anything like a butter-substitute. The credit of this discovery belongs exclusively to Dr. Schlunk. The new butter made under his process is found to contain on analysis 0.0008 per cent of water, 0.006 per cent of mineral stuffs, and 99.9932 per cent of pure fat. It is pleasant to the taste and smell, is of a clear whitish colour, something between our buffalo butter and the tinned article imported from France, and can be sold at considerably less than half the price of ordinary butter. It is described as singularly free from acids, easily digestible, and incomparably healthier and better as an article of diet than the cheap poor butters and oleomargarines with which the European and American markets are flooded. The nuts required in this new industry are imported from India into Germany, where the largest coconut butter factories are in operation, in steadily increasing quantities, and supplies are also obtained from the South Sea and Coral Islands, Arabia, the coast countries of Africa, and South America. One firm alone in Germany is now turning out between 3,000 and 4,000 kilos of butter per day, the bulk of which is exported to America, where already a large demand for the article has sprung up.—*Times of India*, Jan. 9th.

AUSTRALIAN MICA is once again receiving considerable attention on this side, Mr. Richard Baker, the well-known mica merchant of Eastcheap, having interested himself much in it.—*E. Mail*, Dec. 27th.

A QUICK FRUIT TREE BUDDER.—The following note taken from the *Stanford Mercury* of a recent date, gives an unexampled number of buds put in during one day, “Mr. A. Hagger, foreman at Messrs. W. and J. Brown's nurseries at Stanford, budded 1850 Apple stocks, three men tying for him. We believe this ‘beats the record.’” One thousand buds put in is considered to be a fair day's work for a man.—*Gardeners' Chronicle*.

CACAO IN EQUADOR.—The French *Moniteur Officiel du Commerce* for the 23rd May last states that the lack of rain in the Republic of Ecuador inspires very grave fears for the cacao crops of the present year. Besides the drought, such great damage has been done in the province of Imbabura by swarms of locusts that the Government has been obliged to send aid to the starving inhabitants. At present, however, the export price of cacao in the port of Guayaquil has not materially altered.

COFFEE LEAF DISEASE.—There can be no harm in trying the Californian Professor's remedy for *H. mileia vastatrix*, although we have no faith in reviving coffee by this means in Ceylon: planting with shade trees as in Coorg seems the only likely means of getting coffee to do.

THE JARRAH.—A part of the Stand near Exeter Hall has been paved with blocks of this timber, derived from *Eucalyptus marginata*, a native of South-west Australia. The timber is of unrivalled excellence for durability, and is worked with comparative ease. *E. rostrata*, the Red Gum, and *E. leucocoxylon*, the iron-bark wood, are, according to Baron Von Mueller, the historian of the genus, almost if not quite as durable, and even stronger. The durability and immunity from insects, is due to the presence of kino. The services of the eminent botanist, Baron Von Mueller, in making known the species of *Eucalyptus*, in pointing out their useful properties, and in diffusing them far and wide, can hardly be over-estimated.—*Gardeners' Chronicle*.

INDIAN INVESTMENTS.—Discussing this subject, *Allen's Indian Mail* winds up:—When a London “financial” paper tells its readers, as one did a few days ago, that there is no mineral wealth in the Deccan—no profitable indigo planting in India, and no “gems” in Ceylon except those which come from Birmingham—what is to be said? Shall a similar reply be given as that given of old to the doubter of any good thing in Nazareth—“Come and see”? Or shall we imitate the candid courtesy of Junius in one of his celebrated letters, and say to the “financial” calumniator—“Sir, I shall not call you a liar, but with all the politeness possible I shall proceed to prove you one!” Perhaps the latter will be the more satisfactory arrangement for our purpose.

KURAKKAN, which is supposed to be a hurtful food to natives of Ceylon, is thus noticed in a review in the *Indian Agriculturist* of an agricultural show in Mysore:—

Next comes *Eleusine coracana*, *Ragi*. This crop is remarkable for its hardiness in times of drought and abundant fertility when the season is favourable. It is the flour of this produce that Mr. Mukerjee, so well-known in connection with the Economic Department of the Indian Museum, has been experimenting with for the consumption of the poorer classes in England. The finest *ragi* is sold in Mysore at six pies per seer and Mr. Mukerjee hopes to sell the flour in London at one penny a pound. The grain can be stored without injury for many years, and it is due to this property that periods of scarcity are tided over with comparative safety.

DISCOURAGEMENT OF LADANG CULTIVATION.—With the object of discouraging the cultivation of ladang and encouraging the permanent agriculture, the following order will be enforced throughout the State of Perak:—2. On and after the 1st January, 1890, no jungle, except secondary growth of not more than five or six years' standing, shall be felled for ladang cultivation, and, to ascertain what jungle may be felled for this purpose, the following test shall be applied: jungle that can be felled with a parang or golok may be cleared, but jungle that cannot be felled without the use of an axe or biliong may not be cut for ladang cultivation. 3. The fee for permit to fell jungle for ladang cultivation shall be 50 cents for every acre or part of an acre. 4. Any person committing a breach of this order or using land for ladang cultivation which was granted for the purpose of permanent agriculture shall be liable, on conviction before a Magistrate, to a fine not exceeding \$50 for every acre or part of an acre so felled or cultivated, and any Penghulu who knowingly allows a breach of these regulations to be committed in his mukim shall be liable to the penalty herein provided. [The above is from the *Perak Government Gazette*, and evidently refers, under the Malay term of “ladang,” to the process known in Ceylon as “chenaing,” and in India as “jooming.”—Ed.]

RAILWAY SLEEPERS: STEEL AND
TIMBER.SUPPLIES OF WOODEN SLEEPERS FROM THE BALTIC
AND AUSTRALIA AND FROM OUR LOCAL FORESTS:THE BEST TIMBER-TREES TO GROW IN
CEYLON.

We fear that KARRI and KAURI will continue to be confounded, notwithstanding the wide difference between a Eucalyptus and a Pine. Baron von Mueller seems to have been acquainted only with the white-wooded variety of KARRI, but even of this kind he stated that it was particularly in request for large planks, for spokes and fellos for ship-building and even for masts, and that a balk of this timber which had been exposed in the wash of the tides at ape Leeuwin for 26 years continued sound. In "Timber Trees and Timber," Laslett, however, does not speak favourably of its use for ship-building or architecture in England, but it is probable that injury to the texture in felling was the objection to the samples sent. Its power to resist the influences of our soil and atmosphere will soon be decided, for the KARRI sleepers from Western Australia have been in the ground for nearly a year now. The botanical name of KARRI is *Eucalyptus diversicolor*, and the synonym *E. collossea* indicates the enormous size to which it attains.

The KAURI pine, on the other hand, is botanically *Dammara Australis*, and we are not aware that timber from this grand tree has ever been tried in Ceylon. Ships went to New Zealand for masts of it, long before the islands became British Colonies. It has been known to measure 180 feet in height and 17 feet in diameter of stem, the age of such a tree being estimated at seven to eight centuries. It is used for masts, for decks of ships and for numerous other purposes, from bridges to sounding boards of pianofortes, and stethoscopes, and is reckoned one of the most durable of the conifers. It is easily worked and takes a high polish. The tree yields vast quantities of gum which makes an almost colourless varnish. This very valuable tree ought to be tried in our mountain regions.

But KARRI and KAURI are not the only trees which are confounded. How many of us are aware of the distinction between our two indigenous trees DAMBU and DAMBA? The first was noticed in our Friday's issue as botanically *Hemiggyrosa canescens*, prevalent in our dry zone, and likely to answer well for railway sleepers. DAMBA (merely another form of "Jambu," whence Jambudwipa) is botanically classed by W. Ferguson under the MYRTACEÆ, and is, of course, one of our numerous *Eugénias*. The tree is well-known to planters in our higher forests as yielding, next to the red doon, the best shingles. The colour of the timber is a deep red. Mr. W. Ferguson, in placing the DAMBA under MYRTACEÆ, wrote of it, after having described several *Syzigium*s:—"The DAMBA S. a good sized tree producing a fragrant gum and useful timber, is a species of this genus, if it be not *S. Gardneri* of Thwaites. The other species are also likely to produce good timber."

The upcountry tree is distinctly known to the natives as the DAMBAGAHA and the name is prominent in Dimbula on physical features, such as the Dambagastalawa river, which, rising on Horton Plains and leaping in grand cascades over the cliffs above Elgin estate, flows through Molesworth's "Railway Gorge"; also the Dambagastalawa mountain which is a well known "trig. point." Planters may occasionally use the form Dambu for this tree, but we

can find no *Dambu* in Clough's Dictionary except as a name for a jackal or a thing partially burnt, and as the Elu form of Jambu. In Trimen's list of Ceylon plants there is neither Damba nor Dambu, but only Dan or Hin Dan, for *Eugénia caryophylloea*, and Maha Dan for *E. jambolana*, the Tamil Naval. For *Hemiggyrosa canescens* Trimen gives no native name.—Philologically, jambu, dambu, damba and dan are mere variations of the same word. It is the Forest Department, therefore, which for the first time, we suppose, has applied the native term *Dambu* to a dry zone tree, *Hemiggyrosa canescens*, belonging to an order, *Sapindaceæ*, which has no affinity to the *Eugénias*. We, naturally, under the circumstances, changed *Dambu* into *Damba*, and wrote of the upcountry Dambagaha. But in a proof submitted to him, Col. Clarke carefully replaced *Dambu* as the native name and substituted for our note "DAMBU (not Damba) is a well-known tree in the dry zone and should do well." It is beyond doubt, therefore, that the officers of the Forest Department have satisfied themselves, that *Hemiggyrosa canescens* is known to the Sinhalese as *Dambu*, although our Botanists, from Moon to Trimen, have failed to notice the fact.

So much for DAMBU and DAMBA, which, closely allied in nomenclature, are widely separated in natural order.

We now proceed to notice the "Sleeper" Committee's Report.

The Committee on railway sleepers commenced its sittings on May 22nd, 1889, and reported, with copies of the evidence taken, on 12th October following. The members were Col. Clarke, Surveyor-General; Mr. Pearce, General Manager, Ceylon Railways; and Mr. Waring, Chief Resident Engineer, Haputale Extension. The immediate object of inquiring into the quality and cost of a consignment of Karri (*Eucalyptus diversicolor*) sleepers received from Australia was speedily attained, the verdict being strongly in favour of the sleepers, the timber of which, when polished, closely resembles mottled mahogany. This we know, from a walking-stick of the timber, presented to us by Mr. Davies, from whom the consignment of sleepers was received. Mr. Stables, then employed on the Haputale railway extension, gave the Committee the results of his experience in India, as placing Karri sleepers in the first rank, even before teak, while Mr. Davies of the Government Factory spoke well of the sleepers, only saying that they ought to have been better seasoned. This remark, although there was really little occasion for it, led the Committee very properly to recommend arrangements for examining consignments of sleepers before being shipped for Ceylon on account of Government. This question of seasoning, the importance of which cannot be too much insisted on, formed part of the inquiry with reference to local timber. Mr. Davies was of opinion that logs ought to be allowed to lie in the forest one year before being sawn, while another witness thought that three months' seasoning of the log and three months more of the sawn timber would suffice. No reference was made to the system of seasoning in water which is so frequently adopted in Ceylon, and we suppose with benefit in the case of most timbers? We suspect much of the Baltic fir which comes to Ceylon in the shape of sleepers is imperfectly seasoned or not at all before being creosoted. The tar odour of course repels white-ants, no matter how the sleepers are stacked; and one of the main objections made to the Karri sleepers was, that, stacked on ground swarming with white-ants, the insects attacked them, seeking out weak places, of which they found but few. Once in the "way" (the railway line), uncreosoted

sleepers are just as safe from white-ants as those most thoroughly saturated with the spirit of tar. The Committee went to the extreme of cautious reserve in saying that the cause of this exemption was unknown, unless it was accounted for by the vibration produced by passing trains. Quite sufficient, surely, even if gangs of workmen were not constantly stirring the ballast and adjusting the sleepers and rails. The termites can only pursue their destructive operations amidst perfect quiet, either inside the substance operated on, or under coverings of earth, many of which covered ways may be seen scoring the walls of neglected buildings, which rest on earth in which white-ant nests exist. We have seen bees build beneath a frequented staircase, but the vibration would speedily dislodge white-ants if they tried the same experiment. Our old friend Dr. Elliott was wont to circumvent white-ants by placing a plate of zinc under the wall plates of buildings. The moment a white-ant got on the zinc, the formic acid of the insect acting on the metal produced electric action, and then of the ant it might be said that

"The subsequent proceedings interested it no more." Railway timber in the line is safe from the attacks of these destructive insects, from the causes we have mentioned; and railway buildings, like others, can be made secure by placing tar in the foundations and by the use of cement, concrete or asphalt for floors, over earth freed from the nests of the insects. From what we saw of the fine solid karri sleepers when some of them were being put down on the seaside line, we feel perfectly confident, that, if used in buildings instead of being placed in the way as sleepers, white-ants would gain nothing by attacking them except what Burns wished the enemies of his countrymen,—

A twal' months' toothache.

A few quite external cracks on some of the karri sleepers were very properly dismissed as of no consequence, any more than some external change of colour when submitted to sun and weather exposure. As regards seasoning, too, Mr. Davies seems, as we have said, to have scarcely had ground for his only qualifying remark, for the Committee reported that they had one or two of the piles taken down and "the sleepers presented no appearance of warping or seriously cracking such as would be indicated by the exposure of unseasoned wood to the sun." There are few woods, however well seasoned, which will not, we should think, "sweat" if stacked without care for ventilation, and exposed to such a climate of heat and moisture as ours. The cost of the sleepers, considering their exceptionally good quality and the fair certainty of their longevity, was moderate, R5-27 each, in the store-yard, against R6-25 to which satinwood sleepers have now risen. The cost of creosoted fir sleepers is of course much lower, imports of over 150,000 between 1880 and 1888 having ranged between R2-72 and R3-79 each; but then the average life of such a sleeper is only 8 years, and much less on the seaside line, where wood, equally with iron, suffers specially from the saline moisture. Hard wood sleepers, such as karri, red and blue gum, satinwood, doon, millila, &c., average at least 12 years.

I
SATINWOOD AND MILLILA SLEEPERS DIFFICULT TO OBTAIN—TREATMENT OF SOFTWOOD SLEEPERS—RISE IN PRICE OF BALTIC TIMBER—COST OF THE SOUTHERN RAILWAY—DISTRIBUTION OF WOODS SUITABLE FOR SLEEPERS—AUSTRALIAN TIMBERS—THE SLEEPER COMMITTEE'S REPORT—THE FOREST AND RAILWAY DEPARTMENTS—A STRONG ARGUMENT FOR RAILWAY EXTENSION.

Could an abundance of satinwood and millila sleepers be obtained at a moderate price, of course nothing better could be desired. But both

woods are in active demand for cabinet and house work, while our forests are full of hard woods believed to be excellently suited for railway sleepers and which can be supplied at rates equally satisfactory to the Forest and Railway Departments, but which are not in demand for ordinary purposes, probably because they are not sufficiently known and have not been fully tried as they now will be, by the most severe of tests, burial underground, or worse still under ballast pervious to all the rain that falls. If good hard wood sleepers can be supplied at about R3-50 each, the railway will take considerable quantities of them, to be used exclusively in some places, or alternately with the creosoted fir, on sharp curves. In those places the ends of the soft wood sleepers are so apt to get broken up from constant re-spiking and to be crushed by the weight of engines and carriages, that with such sleepers alone it is most difficult to keep the line "in gauge." Appended to the report there is a list of no fewer than 61 native hard woods, most of which it is believed will answer for sleepers, while the question of creosoting or otherwise treating such soft woods as hora, hal, and *Alstonia scholaris* has not been entered on. The late Mr. W. Ferguson shrewdly suggested that such soft timbers might be preserved by "gambier" gum, obtained from the leaves of native plants. That question of using sleepers of local soft woods, treated with antiseptic preparations, may some day arise; for we understand that since the estimates for the section of southern railway to Bentota were framed, Baltic timber has gone up very considerably in price, while iron is also dearer; and we may add, while on the subject, instead of R850 per acre sufficing for cost of land taken, that sum has had to be doubled. With all this, it is gratifying to be assured that this, which is likely to be the most expensive section of the southern line, is not likely to cost more than £3,500 sterling per mile. This for broad gauge, mind; and those who want to saddle the colony with break of gauge to narrow ought to see a letter which Mr. Trevelthick, formerly of our Railway, has written from Japan. There the 3' 6" gauge limits speed so much that the railway trains cannot compete with the coasting steamers. If a line to Jaffna cannot carry passengers faster than the colonial steamer can, it is not likely, we submit, to be a success. But narrow gauge, apart from its other disadvantages, means slow speed. We can scarcely admit that we have, in such remarks, digressed from our subject. There is no doubt that the standard gauge of 4' 8½" would have met all our wants. But India having adopted 5' 6", it was natural we should follow suit. This gauge secures speed and safety combined, and any saving on the construction of a three feet, six inches gauge line would speedily be lost in working, apart from the inconveniences of break of gauge and the impossibility of exchanging rolling stock. If a mile of broad gauge on the southern line, through dense groves of coconuts, costs only £3,500 per mile, it seems perfectly certain that a northern line ought not to cost a shilling more than £3,000 per mile. If such a line were once extended to the vast and prolific forests of the North-Central Province, the problem of a sufficiency of good and cheap sleepers of local origin for our whole railway system would be at once and favourably solved. Let us hope that Sir Arthur Havelock may be able to commence this great work, while completing the southern line to Matara, within 4 miles of the noble lighthouse that now marks the southernmost point of Ceylon,—DONDRA HEAD, which looks across the unbroken ocean expanse to the ice-fields that surround the Antarctic Pole.

When extensions reach Matara southwards and Anuradhapura en route to the north, sleepers will be required in far larger numbers than the 15,000 per annum which the Forest Department is now asked to provide, and which, we doubt not, it could supply many times over with ease. The 61 species of timbers deemed suitable for trial as hardwood sleepers, it is stated, "are found distributed, some in the dry zone and some in the wet zone, so that each province can contribute its quota of the total number required." Mr. Broun, too, with his practical knowledge of forestry, goes counter to the popular idea that timber grown in a dry district is necessarily superior to the same species grown in a moist district. In Australia, we rather think, jarrah and karri, grown in a dry climate and on hard, rocky, ferruginous soil, are deemed superior in quality, from the conditions of soil and climate. On the other hand, the red gum, which yields one of the finest timbers for railway sleepers, street pavements and similar purposes, flourishes in damp soil, by the borders of rivers and lakes. But in all cases, we believe red-tinted timber is deemed superior to white, the superiority being probably due to the presence of gum kino. Mr. Stables in his high testimony to the merits of karri timber was careful to say that he spoke of the red variety, not the blue. We have never heard of a blue-coloured karri, only of a red (brownish red) and a white, and Mr. Davies, when we met him in Australia, was emphatic in describing the red as beyond question the superior. His forest in Western Australia, of which and the sawing establishments we have some fine photographs, consists entirely of the red karri. The white he deems unsuitable for railway sleepers, while he claims with good reason the highest possible position for the red, which alone he supplies. Mr. Stables, who had four years' practical experience of karri sleepers on Indian lines, considered them, all round, the best sleepers he had met with in his experience, and at R5-10 at the ship's side here a cheap article compared with what they cost in India. "Karri is the finest wood for sleepers I have ever seen." We have not the slightest doubt that the result of the trial made in Ceylon will confirm this opinion. We have already remarked how closely our own red doon (which has long passed the experimental stage) resembles, in colour and consistence, the Australian karri timber. The doons, which are not only indigenous but peculiar to Ceylon, as is the fine halmilila (one of the best timbers existing),—the doons are, no doubt, harder and more difficult to work than the karri. In the evidence given before the Committee we observe that much stress was laid on the employment for conversion into sleepers of the variety described as "Yakahalu." This as written would mean demon-like, but the terms for demon and for iron in Sinhalese so closely resemble each other, that they may be confounded. We have no doubt that the proper term is "Yakadhalu": iron-like doon, from its hardness of texture. Of course, experience must decide, but next to doon, we should think that the ubiquitous KUMBUK (*Terminalia glabra*), often of enormous growth, ought to be one of the most prolific sources of good sleeper wood. Wherever there are rivers or pools or tanks, there is the kumbuk with its thick, calcareous bark, covering trunks of five tons in weight, and so large, when old, as to present cavities in which families might dwell and in which, we were told, bears actually make their abode in the northern and eastern jungles. The mode in which fresh timber and bark form over the edges of these weird tree-caves is wonderful, and the trees when in blossom are sweet-scented and "beautiful exceedingly." We retain a lively recollection of blossoming trees scattered over the nume-

rous rocky islets in the river below Kalawewa spill and of the enormous masses lining the Aruviaru, near the Giant's Tank. Colonel Clarke having, in one of his reports, recognized the importance of this prevalent and gigantic tree as a source of sleeper supply, we cannot understand why it does not appear in the list attached to the Committee's Report. It may be because, like doon, the timber has passed the stage of experiment, although this is not stated. Many of the witnesses put this tree forward as amongst the most important of sleeper-yielders. So long as creosoted Baltic fir sleepers can be obtained at about half the cost of hard wood sleepers, of course the economical procedure will be to use such sleepers exclusively on the "straights" of our railways and to alternate them with hard wood sleepers on very steep gradients and sharp curves; but it is quite possible that increased demand for the creosoted sleepers in Europe and elsewhere may render it cheaper as well as more desirable ere long, that timber for the Ceylon railway lines should be supplied from the still extensive forest resources of the colony. With the question of the ability of the Forest Department to supply half the number of sleepers now annually required, viz. 15,000 against an equal number of creosoted fir, the Committee dealt largely, exhaustively and with conclusions more than satisfactory. As to apportioning the cost of new timbers to be tried at the rate of 100 sleepers of each species, a difference of opinion arose. The two railway officers, naturally enough, expressed the opinion that Government, by a vote (of over R20,000,) should supply the trial sleepers to the Railway Department free of cost. Col. Clarke, as representing the Forest Department and the interests of the Government, dissented, protesting against the idea that the success of the vast majority of the timbers to be supplied was at all problematical. Most of them had been used in the arts and otherwise, so as to subject them to severe exposure, and the trial timbers were good and substantial, being the pick of several hundreds,—all doubtful trees being excluded. We suppose, therefore, that the Railway Department will have to pay at the rate of R3 or R3-50 for the trial sleepers. We should think, however, that the "split the difference" principle might be applied; for there can be not the slightest doubt that a series of experiments calculated to establish the general value, and specially the fitness for railway sleepers, of varieties of timber not now in use, but abundant in our forests, will be greatly to the benefit of the Government of the country and the population. To put the question of a supply of 15,000 hard wood sleepers per annum beyond doubt, the Committee calculated that if only 6 out of the 9 provinces contributed each year, thus giving a total rest to each province every third year; and supposing there were only 8 different kinds of hard wood in each province suitable for sleepers, (a very low estimate, as the evidence showed afterwards), even on these moderate data less than 1,000 cubic feet of timber or say 25 to 30 good trees of each of the 8 species would be required as the annual quota from each province, in those years it is called upon to contribute. There can be, therefore, no doubt not only that, with the vast forest areas available, these demands of 200 to 400 trees in all annually from each province would not bring any strain on the forests themselves, but that the removal of the trees would be of advantage in many ways. The Committee, therefore, recommended trials of the 61 species of timber mentioned in the list, with 25 of which we have already dealt. But even the 61 enumerated do not exhaust our hardwood resources. The question is not one of abundance of suitable timber, but of ability, with present labour supply and means of conversion and

carriage, to deliver the sleepers where required at a price profitable to both the Railway and Forest Departments, say R3-50 per sleeper. It was recommended that one-third of the trial sleepers in each sample should be used on the sea-side and main lines, below Rambukkana; one-third above Rambukkana, on the Matale branch and as far as Nawalapitiya; and the remainder above Nawalapitiya. They will thus be tested in all the conditions of soil and climate, ballast and traffic likely to occur in the colony. The sample sleepers will, of course, be carefully and conspicuously marked, with name of species and year of felling, so that no mistake as to the identity of any can occur; and with constant examinations and reports by the Railway Engineer, it is anticipated that even in one year valuable results may be obtained, the minimum final period of trial being three years. Should the reports be favourable and the timber abundant in any limited locality it is believed that the purchase and transport of steam-sawing machinery would be advisable. Several witnesses gave evidence to the effect that thus a saving of 50 per cent might be effected in the sawing. Mr. Huddleston, the Assistant Forester of the North-Central Province, suggested the use of wind power at Trincomalee, and we think the idea well worthy of attention. The Committee also suggested the purchase for the use of the Forest Department of a small elephant establishment to drag timber to the sawing mill. Hired elephants, even in this land famous for its elephants, are difficult to obtain and during festivals unobtainable.

Such is the general tenor of the Report, founded on interesting and valuable evidence, some points in which we shall quote and notice in a further article. Meantime, we cannot help saying that the very difficulty of obtaining full supplies of sleepers for our existing railways, owing to the remoteness of forests which teem with suitable timbers, forms the strongest argument for the extension of railway facilities to as many as possible of such remote localities, or to the nearest proximity to them, without too severe an application of the "Will it pay?" principle. Such Railways would while opening up the country to enterprise and industry, gradually develop traffic which would enable them to be directly profitable ultimately; while meantime they would help largely to make existing lines pay better than they now do.

We now come to the evidence given before the Committee on railway sleepers, and the results of Mr. Cantrell's extended experience in regard to experiments with sleepers, imported and of local timber, are so important that we feel bound to give his evidence in full, except that in regard to the Kurri sleepers, the purport of which has already been stated. Mr. Cantrell stated:—

During my 22 years experience of Railway work in Ceylon I have tried several kinds of sleepers, imported, and native. The imported ones are creosoted Baltic fir from England, red and blue gum sleepers and Jarrah for bridge timber from Australia and Johore Teak. Of native woods I have had experience of Satinwood, Mililla, Kahata, Na, Palu, Mi, Red doon and White doon. Other kinds were tried by Mr. Faviell, the contractor for the main line viz. *Del, Caroo, Dambu* and *Kura*, but of these I have no record, they were all tried in the low-country. With regard to creosoted pine sleepers they have the merit of being cheaper than any other sleeper in first cost. This is important only on the straight and level portions of "the road," but on sharp curves and steep gradients, their life is short and they are comparatively more expensive than others; on sharp curves I should use nothing but hardwood sleepers if we could

get a sufficient supply, but as the supply is short, we use the two kinds alternately. My experience of the sleepers laid on the Nanuoya section of the line is as follows:—

On sharp curves under 7 chains the road was laid alternately with creosoted and hardwood sleepers, the hardwood sleepers consisted of red doon, white doon, kahata, and mi. These sleepers were not applied under Government supervision, but were purchased from planters and others and it is impossible to say whether the woods supplied were really what they professed to be. Experience shows that these woods were not of good quality for sleepers with the exception of the red doon. The average life of a creosoted sleeper may be taken at 8 years throughout the line; the average life of a satinwood, or mililla sleeper, 12 or 15 years, of red gum from 12 to 14 years, of kahata not more than 5 years, of white doon less than 5 years and of red doon about 8 years. Na is not a good wood for sleepers and the same remark applies to palu; but I must qualify this statement as regards palu by saying that the shipment of about 5,000 which came from Jaffna consisted manifestly of immature trees. Creosoted sleepers generally fail from getting too thin at the rail bed owing to the sleeper being cut into by the rail. The ends are very apt to split and to break off when in this condition. The crushing strain and the frequent respiking in these soft woods, in order to keep the rails to gauge, wear the sleeper through. The conditions on the sea side line are in my opinion more unfavorable to creosoted pine sleepers than on the inland sections so that I do not estimate the life of such sleepers on the sea side at more than 6 to 7 years, but including the inland sections the average life may be taken at 8. The life of a Johore teak sleeper is 10 years. Its chief defect is its liability to split, for which reason it requires to be bolted or ringed at the ends. This is the experience of 10,000 of these sleepers and they were exclusively laid on the section between Colombo and Kandy. Their cost in 1876 was R5 each. I prefer satin or mililla wood to Johore teak. Jarrah has never been used for sleepers in the road, but it has been tried for longitudinal bridge timbers. It has a life of 12 years. Its defect is liability to dry rot. Mi and nearly all other native wood sleepers that have been tried excepting satin and mililla fail eventually from dry rot. Mililla, satin and both the red and blue gum sleepers failed eventually from old age. The cost of a creosoted sleeper varies from R2-45 to R3-75. If I could get a suitable native hardwood sleeper at a reasonable price I would use it on the curves exclusively. By a reasonable price I mean R5 for a sleeper which would give an average life of 10 years or upwards. We require from 20 to 30,000 sleepers per annum to maintain those parts of the line at present open to traffic and, of these, we could use as many as 15,000 hardwood sleepers.

Due weight will be given to the qualifications stated by Mr. Cantrell, that the sleepers of indigenous wood used by him were in many cases not carefully identified as to species of trees, or tested as to age and quality of timber, so that it is right that Na, so highly spoken of by many, and other timbers, said to have failed as sleepers, should have a further trial. It seems a great pity that the results of Mr. Faviell's experience should not be available, but we should think Mr. Kendrew must have kept records which could be referred to. The next witness examined was Mr. A. F. Broun, Deputy Conservator of Forests. In answer to the question whether the forests of Ceylon were adequate to the supply of sleepers for the railway he said:—

As far as my Indian experience goes I have no doubt on the point. In support of this view I may state that a tree of 6 feet girth breast high, and I am taking a low estimate, yields at least ten sleepers. That means that 1,500 trees altogether would have to be furnished by the whole island, or roughly 200 trees per Province. A great many indigenous trees I think would give sleepers at least as good as the creosoted pine, which is still being used on the Railway. Large trees of Palu for instance would often yield 120 sleepers. In

stating the probable number of sleepers to be obtained from a large tree I refer to the Metre Gauge Line which has a sleeper 6' x 8" x 4". I do not see why with a vast supply of this and other large trees, such as kumbuk or some of the *dipterocarpaceæ* (Hal, Hora, Mendora and others) the supply could not without difficulty, be obtained. The Kolon, I know has been used in India on the Kumaon and Rohilkund Railway, and although the wood is good in many respects it does not appear to have been able to stand the exposure and after three years the whole stock had to be renewed. I do not see why the following species should not be suitable:—Godapura, Kina, Red or Hill Doon, Daminiya and Pehimbis. About kon I am doubtful, as the Indian tree has not a very good repute and is generally small. Mora and most of the eugenias of which there are many species in Ceylon should be good. Palu, Millila, Nebedda, Yavarana, Keta-kela (this possibly might be too brittle) Del and Gomala. Mi, I should consider a very good wood. With regard to kahata I can only speak of the Indian tree which has not a very good repute and grows small. With regard to Na the main difficulty likely to arise is cost of working and it might probably prove too brittle. The sapu has also a good reputation. The *zizyphus jujuba* and *zizyphus xylopyra* have good reputations as half round sleepers in India but I am doubtful whether these grow to any size in Ceylon. I have had no actual experience of these woods as sleepers in Ceylon but my experience of the use of several of the same species or genera in India as sleepers on several Railways leads me to the conclusion I have formed. Of the others, I speak simply from their reputation as woods or from actual knowledge. In respect to hard wood timbers grown in the wet and dry zone and their respective merits for sleeper purposes it is not a necessary conclusion that a hardwood sleeper of the same species grown in the dry districts has a better quality than hat grown in the moist districts.

With reference to this evidence it strikes us that surely the Government of India must by this time have obtained from the State and Subsidized Railways a mass of information regarding timbers that are in use or have been the subjects of experiment on the lines, which evidence, in a convenient form, could be supplied to the authorities in Ceylon. If not already asked for, we would suggest that application should be made by our Government to the Indian authorities. From the pages of the *Indian Engineer*, we gather that neither Himalayan deodar nor any other timber locally available can compare with sal, just as in Ceylon nothing can excel millila. But sal in India and millila in Ceylon are far too valuable for cabinet and general purposes to be available for railway sleepers and the great object is to prove the fitness for railway purposes of the numerous forest trees for which at present there is no demand in the general market. Broad gauge sleepers are of course larger than metre gauge, the dimensions of the former being 9' x 10" x 5".

Regarding the Karri sleepers, Col. Gorman deposited that the weight of the timber was about 60 lb. per cubic foot, and allowing 3½ cubic feet for each sleeper, the weight of a sleeper is no less than 188 lb. Mr. E. C. Davies had 11 years experience of island timbers but had little experience of Australian wood with the exception of jarra, which has been used by me for piles and strainers in jetty work. I know karri timber by repute only. It has similarities with jarra and is of very much the same color and weight.

Mr. Davies's opinion of the Karri sleepers we have already indicated. He stated:—

For bridge planking and jetties we use Milla, Palu, Satin, Mendora, Sapu, Ranai and Na. I consider any of these would be suitable for sleepers, Milla being the best.

SUPPLIES OF HARD WOOD SLEEPERS FROM LOCAL RESOURCES.

Mr. J. Alexander, Assistant Conservator of Forests, Central Province, who had been more than four years in the Department and was acquainted with the trees in the North-Central, Central and Uva Provinces, indicated the following timbers as suitable for sleepers:—

In the North-Central Province and in the Matale District of the Central Province the following species would I feel pretty confident meet the general requirements: Kumbuk, Mi, Palu, Hulanhik, Kon, the Albizzias; Munnamal, Velangu, Kahata, Nebedda, Godapara, Dambu, Mora and Ketakela, arranged in order of merit as sleeper woods.

In other parts of the Central Province some of these species may be found and of other likely woods, I would mention the red and white Doons, Wa, Dawata, some of the Eugenias, (the Alubo and the various Dambas) Mibiriya, Sapu, Kina Liyan and Galsiyambala. I do not think Rana suitable for sleepers as my experience is that Rana does not stand exposure well.

It will be observed that Mr. Alexander speaks of "the various Dambas," meaning, of course the upcountry Eugenias. Mr. Alexander indicated the places where timber could be obtained and the routes by which it could be conveyed to where it was wanted and added:—

The cost of transport of a log from the North-side of Dambulla is 20 to 25 cents per cubic foot and South of that place about 15 cents, to Matale.

A portable steam engine, keeping original cost out of view, would effect a saving of 50 per cent in cost of sleepers. There was abundance of timber in the lowcountry of Uva, but its carriage up to Haputale could be costly.

Mr. F. Lewis, Forester of the Province of Sabaragamuwa, was of opinion that

Provided the railway are ready to accept sleepers of several species the Province of Sabaragamuwa might reasonably be expected to contribute at least 5,000 sleepers in three years and so on continuously.

The following species would be suitable, arranged in order of merit: kumbuk, doon, (Yakahalu) mendora, panukera, kina (red or hill), alubo, kaddawakku, and bomi.

There are other species, which, although good, I consider of secondary value: godapara, naimbul, kon, madul, pelan, muruta, damba.

I should also certainly include mill- as a suitable sleeper wood, but it is getting scarce in my district. Na may also be added to the above list.

It is curious to see MURUTU (*Lagerstromia flos reginae*) put in the category of inferior timbers, while in continental India it ranks next to teak in value. Mr. Lewis went on to say:—

From Gilimale forest I could supply panukera, alubo, bomi (a good fibrous grained wood), yakahalu doon, kaddawakku, kina, naimbul, madul and muruta. From the vicinity of Kahawatta near Pelmadulla in the Valley of the Weganga, I could furnish kumbuk principally, that particular wood being in my opinion the first on the list. I don't propose to take any other from there, but of kumbuk there are very large supplies.

From the Ebedda Mukalana in the Kuruwitkorle I could supply mi, pelan, mendora, kaddawakku and alubo. From all these timber can be floated down the Kaluganga.

It will be observed that Mr. Lewis regards Kumbuk as No. 1 in his list of suitable timbers. With this testimony and Colonel Clarke's own favourable opinion of this plentiful and grand timber tree, we should have expected that it would be amongst the first submitted for trial as to its fitness for sleepers. If a steam saw were provided, Mr. Lewis held that 50 p. c. on the sawing could be saved.

Mr. A. Clark, Assistant Conservator of Forests, Western Province, was acquainted chiefly with the

timbers of the Northern and Western Provinces, having served in the former 12 and in the latter 2½ years, and was of opinion that the wants of the railway could be easily met, from such local timber as Doon (yakahalu), katakela, alubo, kahata, mendora, liyan, malpetta, mahadan, godapara, daminiya, madaliya, kina, balādamba,

In the Northern Province, palu, yavarana, kumbuk, mi, tammana, hulanhik, kon, mora, the albizzias and milla.

Of course Milla is but another form of Milila, Hal-milla being an almost perfect timber, while Hal itself is ranked with Hora as amongst the most inferior of our timbers. They all have their uses, however, even without being creosoted. Asked whence he expected to obtain the bulk of the sleepers, Mr. Clark said:—

From Puwakpitiya near Avisawella and from Mitrigala 12 miles from Hanwella.

By what route could the sleepers in your opinion be most economically conveyed to Colombo or any other railway station?

By water carriage along the Kellaniganga.

With regard to the present agreement with the railway to deliver Yakahalu Doon sleepers at Kelaniya for R3.50. Is that sum remunerative to the Forest Department? Yes.

If the supply were extended to eight or more species instead of the one, could the rate be lowered.

I think so, but I would observe that in the particular forest in which the sleepers in question were cut the Dun is gregarious.

With regard to the Northern Province from what particular district should you expect to obtain the sleepers required or the bulk of them?

From Irananadu forest, from the South Mullaitivu forests and from Chinavel on the Western coast and thence by ship to Colombo.

What is the freight paid on timber from outstation posts to Colombo.

R8 per ton of 50 cubic feet timber delivered alongside by the Forest Department and delivered at the ship's tackle in Colombo.

It seems to us that red doon (dun), sleepers at R3.50 each are, relative longevity taken into account, cheaper than creosoted pine at R2.50, even if the latter can now be obtained at that price.—Mr. F. A. Stables then testified in favour of karri sleepers as we have indicated. He considered a broad gauge sleeper 9' 0" by 10" by 5" cheap at 7s. His experience at the Cape as well as in India led him to prefer hard wood sleepers to creosoted pine. He had seen no timber on the Haputale line to compare with karri. Capt. A. M. Walker, Assistant Conservator, Southern Province, was examined by letter and gave very interesting and valuable information. He believed that the wants of the railway could be easily supplied from island resources. We copy as follows, question put and answers given:—

It has been given in evidence that the under-mentioned species are likely to yield a good hard wood sleeper. Can you furnish for your present Province any of the species therein named; if so, which? Can they be supplied in sufficient quantity to yield in consecutive years the outturn required? Palu, Hal, Hora and other Dipterocarpaceæ, Godapara, Kina, Red Dun, Daminiya, Pehimbiya, Kon (doubtful) Mora, the Eugenia class, Millilla, Nebedda, Yavarana, Kehakela, Del, Gomala, Mi, Kahata (doubtful), Sapu and Zizyphus (doubtful).

I can supply six out of the different woods named which can easily be supplied in sufficient quantity to yield in consecutive years the outturn required.

They are Palu, Hora, Dorana, Godapara, Kina, Milla and Del.

If your Province falls short of having 8 species comprised within that list, can you suggest other species to make up 8 or more? If so, what are they?

I have added the names of seven other woods which in my opinion should be very suitable for sleepers and which can be supplied in the quantity required yearly.

Additional list of woods considered suitable for sleepers—(7) Yakahalu (Doona of some sort resembling red Dun, an excellent wood for bridges &c.). (8) Wanna Mi, (Bassia), a very good timber. (9) Tawana ("Dichopsis petiolaris" probably), a good wood much used for house building have seen it used for Bridge planking, said to last well. (10) Kiri Kembil ya ("Dichopsis graudis"), resembling Tawanna. (11) Uruhonda ("Lasianthera apicalis"), said to be a good and durable wood, should I think make a good sleeper. (12) Heddawakka ("Chatocarpus castanocarpus"). (13) Kumbuk. This should I think make good sleepers. (14) Pepiliya ("Aporosa atifolia"). (15) [blank] or Welepiyana. ("Ani-ophyllea zeylanica"), used for shingles, posts &c.

These two last named woods are to be found in large quantities, but I am doubtful as to their durability in soil. Nos. 7, 8, 9. Leaves of these trees were forwarded to Dr. Trimen for identification but flowers and fruits are required to decide with certainty.

I have given Hora, Tarana and Del because they are in the list of woods which accompanied the questions, but they are undoubtedly soft woods and said not to last under exposure.

I could enumerate many other woods which I consider preferable to Hora or Del.

We are greatly surprised to find Capt. Walker classing the fine timber of Del (*Artocarpus nobilis*) with Hora. Surely Del is far and away superior? The great value of the series of experiments now being made will be more definitely to establish the relative values of timber about which at present wide differences of opinion exist.

Noticing next the resources of the Eastern Province, Captain Walker said:—

Of the species enumerated can be supplied in sufficient quantity, viz. Palu, Kina, Kon, Mora, Milla, Yavarana and Naval ("Eugenia, Jambolina").

To these may be added the following found in the Province. Kumbuk, Piri ("Eoelendron glaucum"), Tumpali ("Vatica obscura"), Heddawakke, Ka'othai ("Chickrassia tabularis"), and Magala ("Mimops elengi"). This is a fine wood strong and very durable, it is not so liable to crack and split as Palu, it is to be found in most forests in the Batticaloa District, but very plentiful in none. I may also add Venanku ("Pterospermum suberifolium"). This is plentiful in all the Forests but I am doubtful as to its durability.

Capt. Walker then gave useful evidence as to the routes by which timber could be conveyed, from which we gather that all along its course the southern railway will be within easy reach of timber suitable for sleepers. Capt. Walker advocated the sawing up of the timbers in the forest.

Mr. H. F. C. Fyers, Assistant Conservator, North-Western Province, agreed with the other witnesses as to a sufficiency of forest resources, and wrote:—

The following are the species named in the list sent that can be supplied from the province. (1) Palu; (2) Hora; (3) Millilla; (4) Yawarnai; (5) Del; (6) Kina; (7) Mi; (8) Mora; not in the list (9) Kumbuk; (10) Lunumadalle.

He added that Kumbuk and Lunumidel'a could be supplied in large quantities. The bulk of sleepers would be obtained from the Kuranegala and Puttalam districts. He added:—

I expect to be able to get a very large number of Millilla sleepers from the forests about Giriulla. These can be transported without any difficulty to Allowwa (where a station is now being built) Ambepussay and Mirigamma. There are roads leading to all these stations and the carriage should be cheap, the forests are all within about 15 miles of the railway stations. A portable saw mill he considered indispensable.

We should think that the millilla timber could be more profitably disposed of by the Forest Department than in the shape of railway sleepers.

Mr. J. E. L. Huddleston, Asst. Conservator, North-Central Province, truly represented the forest resources of that Province as abundant. The only

difficulty was connected with labour, and that was not insuperable. But illicit chenaing ought to be checked. Palu alone could supply twice the demand. About 12 species of the trees named by the Committee would bear removal, at the rate of 40 trees per annum (with rest every 3rd year) the forests themselves being benefitted thereby. "A requisition which would ruin the forests of another Province would (happily) be scarcely noticed here." Modes of transport were then explained, water carriage being possible to a considerable extent. The cost of a portable steam engine could be paid by the loss and labour saved in cutting a few thousands of trees. Even a windmill erected at Trincomalee might save a mint of money.

The inquiry closed with the evidence of Mr. Cantrell that the trial timbers would require a period of 3 years for full test.

Of the list of 61 timbers appended to the report, a good many have been already noticed and others we may deal with on a future occasion.

WEST INDIAN PAPAWE IN CEYLON.

Mr. H. Pestonjee, the well-known Parsee proprietary planter, whose name has been respected here since the time of his arrival, in the same vessel as Governor Sir George Anderson from Mauritius, in 1850,—has just made a very useful addition to the fruits of the island. This is the West Indian papaw, seeds of which Mr. Pestonjee got down from Bombay about a year ago. At his residence in Dematagoda, the tree has grown so well as in six months to be bearing fruit, and a specimen of the fruit brought to us shows that it is a magnificent improvement on the ordinary papaw. Mr. Pestonjee has seen the fruit so large as to weigh 14 lb.; the one before us is 6½ lb., and we are told the edible portion is very much finer in flavour, while the seed occupy an insignificant part in the centre. Mr. Pestonjee compares the fruit to the best pineapple; we shall be able to report later on as to this. Mr. Pestonjee has sent seed to his estates of Debedde and Wewisse in the Badulla district where many years ago under old George Morrice, he introduced superior figs. Mr. Pestonjee has also distributed seed among several friends and all report that the tree does well. He feels sure it will grow and produce better upcountry than even in Colombo.

COFFEE AND CINCHONA IN DUMBULA.

UPPER LINDULA, JAN. 17th.—The weather is perfect just now: occasional rain and hot sun—this makes the tea flush. Estimates for six months ending December are short with most people. This kind of weather brings the trees forward rapidly, and we expect better results the half-year we are in. Coffee is looking wonderfully well. The yield for the season just closing has exceeded estimates everywhere. Grub at the roots is our most deadly enemy; the coffee tree would, I believe, especially in these young districts—throw off all other pests if the roots were not disturbed; the "root of all evil" is the white grub. One is inclined still to believe in coffee after walking through acres of fine, healthy trees in the Agras, and some coffee over here, in the Railway Gorge, does not look so bad although sadly neglected for years. Had I the money from the owners of this place, "Cymru," I should have a couple of hundred coolies pruning. I would do this and leave the tea flush to take care of itself! I hope the man who buys this estate will not root out the coffee. I do not agree with Mr. Hamlin that people are

harvesting cinchona because the trees canker. There is nothing like the extent of canker now to what it was 8, 10 and 12 years ago. The difficulty, these years, is to keep the cinchona from growing! It grows on sides of steep cuttings and in drains and on the sides of paths, and it also grows now where it refused to grow 10 and 12 years ago. Cinchona kept most of us afloat, kept body and soul together when the parent (coffee) was dying and before the child (tea) had grown up. Cinchona will be a grand spec yet, and to root it out of the ground is a sin. The syndicate will do more harm than good. At present buyers are aware we have bark on the trees; very soon they will know we have both bark on the trees and piled in our stores, and as long as they know this why should the price go up? The process, I mean the business, is unnatural: when a man has produce to sell, let him sell it and let all have a chance. There are lots of tea planters, in all districts, who do not like to see a cinchona tree left in their tea fields; this is quite sufficient encouragement for cinchona growers without storing their bark in Colombo. Best thanks for the photograph of our future Governor. He has a look as if he would suit us! He has lots of work before him.—"Northern Arm," "New Docks," "Railway to Galle and Matara," "New Colombo Post Office," "Railway to Ella," "Seaside drive to Mutwal." Have something instead of that filthy Lotus Pond and widen Chatham Street 20 feet. A. H. T.

AN AMERICAN VIEW OF THE LONDON TRADESMAN.

HOW HE DOES BUSINESS AND HOW HE "DOES" THE AMERICAN.

Mr. G. W. Smalley writes in the *New York Tribune*—

HIGH PRICES AND ADULTERATION.—Tea, sugar, coffee, and many other things are notoriously not always what they pretend to be, nor is the pound always a pound. The plain truth is that the London tradesman is not content with honest profits, no matter how large. He grows fat on dishonest profits. He and your servants are in collusion to rob you, and rob you they do and will, spite any scrutiny or supervision possible to enforce, is no novelty. There is a kind of tradition that the British manufacturer and the British merchant, at some unknown past period, prided themselves on making honest goods and selling them honestly. A great authority, perhaps the greatest, in such matters, once told me his opinion on the subject. There never, was, in his opinion, a foundation for this tradition. There was, perhaps, a time when things were not so bad as now, but never a time when adulteration and fraud were not habitually and generally practised.—*St. James's Budget*, Dec. 27th.

[Adulteration and fraud exist exceptionally, but the above is gross exaggeration.—*Ed. T. A.*]

NOTES ON PRODUCE AND FINANCE.

Has a new alkaloid in tea been discovered? According to the *Journal of the Pharmaceutical Society*, Messrs. Pau and Courley, who have been carrying on some investigations upon a sample of tea, have found out during their experiments an interesting substance, to which they have given no name; it is certainly an alkaloid, and it is neither theine nor theobromine. As subsequent investigation may prove this substance to be identical with theophylline, which Koseel obtained from tea some time ago, chemists can afford to wait without becoming over excited on the subject.

"Tea planting in the Caucasus" runs the "Sea Serpent" close as a rival newspaper heading in dull seasons. The *Journal de St Pétersbourg* usually supplies a little interesting information under this head at brief intervals, and the latter is that with a little perseverance the efforts made on the littoral of the Black Sea, between Batoum and Soukhoum, to acclimatise the tea plant will lead to the appearance of veritable plantations. The first tea plant was imported into the Caucasus about half a century ago, and cultivated in the public garden of Soukhoum. The attempt succeeded, but, as is the case with many innovations, it was not persevered in because of the slowness of the development of the enterprise. Much time is required for the development of the cultivation of the tea plant. The Tiflis exhibition has, however, proved that it exists. Prince Eristow has exhibited a tea plant of superb growth, being forty years old. This tree, with its flowers and fruits, is one of the ornaments of the exhibition. Colonel Solovtsov has presented other tea plants five years old, cultivated in the environs of Batoum and in perfect condition. All these plants grow in the open air, and the seeds are so abundant that M. Solovtsov has gathered sufficient of them to sow next year a half district of land. As to the quality of Caucasian tea, all rumours as to its alleged bitter taste or its so-called poisonous properties are, we read, not based on fact. We have heard all this, or something like it, several times before.*

Some tea from Fiji, the Alpha estate, sold last week at an average of 8½d per lb. Travancore tea from several gardens was sold. The highest averages obtained were by the "Penshurst" estate, 1s 1½d and the "Poonmudi" estate, 11d.—*H. and C. Mail.*

LONDON NOTES AND COMMENTS ON CEYLON TOPICS.

The recent "boom" in the Ceylon tea market, far beyond anticipation, has to a fair extent reacted on our export of tea machinery and related requisites for which a good enquiry has existed. The cost of most of these has been increased by the late rise in the metal market, consequent on dearer coal and higher wages. This advance will no doubt be felt in the manufacture of the patent steel tea packages which have come into demand during the present year.

The *Tea Gazette* animadverted strongly and properly on the Stock Exchange gambling lately introduced into the Mining-lane market under the name of the Produce Clearing House. It says:—"A market, according to old-fashioned ideas, is a place where commodities are bought and sold; but of late years produce markets have largely followed the bad lead of the Stock Exchange, and become to a great extent centres of mere gambling. The evil has been largely intensified since the establishment of the Produce Clearing House and the terminal market arrangements, &c. By these a spirit of gambling has been introduced among small dealers, particularly on the Continent, who operate on the remote chance of an easy profit; but the frequent consequent collapses have proved most detrimental to the wholesale dealers here, who now find this trade too hazardous, and are really dubious of trusting anybody. Brokers, financial houses and others who would be less of a pest to commerce if they had kept in their proper sphere, the turf, have, done very much to disturb legitimate arrangements, and we have by no means seen the end of the mischief that these harpies will effect."

"We observe," says the *Gazette*, "that of late much attention has been paid in the columns of the *Financial News* to tea, coffee and other commodities which are used as gaming counters in the Produce Clearing House, and this is likely to increase the undesirable Capelcourt methods which are so injurious to the community when applied to food products, although, of course, the successful gamblers reap a rich harvest. We would next

ask, is it compatible with the interests of produce dealers that produce values should be largely at the mercy of sets of gamblers by whose tricks and dodges business is severely harassed? And would dealers be well advised to discriminate against those brokers (it is unnecessary to name them here) who, for the sake of extra commissions, aid and abet a system which is most prejudicial to legitimate business."

The local Manager of the Ceylon Gemming and Mining Syndicate, Mr. Harding, has left for Colombo to make arrangement for the prospecting tour of Mr. Barrington Brown, who has quite recently taken his departure for the same destination. Government has originally fixed its royalty on gems taken from crown lands at 20 per cent. on the net profits, though why this should be demanded when native gemmers are permitted to dig on payment of a very small fee only, is difficult to understand. However, we learn that the local authorities are now disposed to accept a much smaller royalty in addition to a moderate annual rent.

When the Syndicate has established itself, and obtained data on which to proceed, it intends floating a Company, with a capital of £250,000, whose operations will probably embrace plumbago mining.

A wrapping machine for fruit is the latest outcome of American ingenuity. This is a machine for wrapping fruit for shipment, a metal carrier moving the wrapping paper forward to where the fruit are fed, a clamp pressing the edges of the paper in necklike form round the fruit while the fruit-holder and clamp are rotated so as to twist the wrapper round the fruit, a discharger then forcing it out.—*Ceylon Advertiser.*

Plumbago, in practically inexhaustible quantities, is reported to have been discovered eighteen miles from the Lower Blackwood coal seam, midway between Vasse and Quindalup in Western Australia.

TROPICAL PLANTS IN THE RIVIERA.—The new *Bulletin* of the royal Gardens at Kew contains an interesting report on the cultivation of tropical and sub-tropical plants in the French and Italian Riviera. In a preliminary note Mr. Thibetson Dyer explains that nowhere have these plants been made the subject of experimental cultivation on so vast a scale as in the Riviera. The exceptional conditions of the climate have tempted persons possessed of horticultural tastes and considerable wealth to try freely in the open air a great variety of plants ordinarily to be seen in Europe only under glass. With a view to ascertaining what had actually been done in this direction, Mr. Dyer was authorized by the First Commissioner of Works to despatch Mr. Watson, Assistant Curator at Kew, to report on the subject. During October this gentleman visited a number of private gardens between Hyères and Mentone, especially the famous gardens of Mr. Hanbury at Mortola. In his report Mr. Watson mentions a considerable number of palms, bamboos, cycads, agaves, yuccas, &c., which from their rarity and supposed delicate nature would not have been expected to thrive even in such a favoured region as the Riviera.—*London Times.*

RANGALA, Jan. 17th.—I am glad to say it is raining again; it fell heavily last Sunday and Monday, over 4 inches being measured during the two days—that is on the lower estates, up above it was much heavier. A slight drizzle on Tuesday and Wednesday and heavy again yesterday and this morning; it is good soaking rain, almost every drop going into the ground, no wash visible anywhere. It is doing much good and will start us all plucking merrily in a few days. The upper Rangala estates planted on new land are giving 400 lb. made tea per acre. At one time such good results were scarcely hoped for. Tea on old land is likewise steadily improving, we move along slowly but surely, age in both old and new land being the *sine qua non* here. I hear a big theft of cardamoms took place on Tuesday night either on Cottaganga or Gonawelle; a gang of thieves are on the move again and will want cooking after sharply.

* In the Caucasus, as in the United States, tea will, doubtless, grow, but the labour question stands in the way of profitable enterprise.—*Ed. T. A.*

Correspondence.

To the Editor.

CULTURE AND PREPARATION OF TEA:
MR. J. HOLLOWAY'S OPINIONS.

Wategama, December 29th.

DEAR SIR,—In reply to your memo to me, "What say you on tea culture and preparation sent some time back?" I did not think anything would be left for me to write about, seeing so many replies; but after waiting for a long time I find that your second question, the one of greatest importance to Ceylon tea planters, has not received that attention as yet which it ought. It is in my opinion of the greatest importance to tea planters now and hereafter.

1. The strength (body) of the tea must be obtained in the field, which can be got by careful cultivation, pruning and plucking.

2. The flavour of the tea partially depends on the quality of soil in which the plant lives, the surrounding atmosphere, and the balance on treatment in the factory.

Remarks.—The planter must, in the first place, learn to judge a full strength leaf by its colour and taste while on the bush; next find out ingredients (if any) deficient in the soil where the leaf has not got the proper colour or taste. By close attention to your best tea and soil, you will soon be able to know your full body tea as soon as you see it and be more certain by tasting as well. There is not the slightest doubt we have many estates in Ceylon where very little attention need be given to manuring for some time yet, as their soil and climate are all that is required; on the other hand there are estates which without assistance give a small outturn of leaf and even that leaf makes a poor tea, whereas if proper treatment was given, a much larger outturn of leaf could be obtained, and from that leaf could be made a first class tea. That tea can be improved in strength and outturn by cultivation I have proved to my satisfaction: even on poor soil, you can obtain a good outturn and good prices for your tea, often better than from estates which have good soil &c. Sometimes your soil appears poor and plants do not thrive, yet on examination very little help may be required, but that little must be given or your soil lies dormant, plants will not thrive and your tea is without strength or flavour. *Cattle manure*, jungle soil or vegetable compost: one of these three should always form the body of the manure; add to this such other manures, patent or otherwise, as you may require for the different soils you have to assist. Give it in time and do not wait too long when double or treble the quantity of manure will not have as good effect as the small quantity would have done if given earlier. A liberal expenditure carefully laid out by the superintendent pays better where soil is poor, than a starving system, with poor returns, estate deteriorating. *This I have proved in coffee, cinchona cacao and tea.*—Yours truly,
J. HOLLOWAY.

CINCHONA BARK EXPORTS FROM CEYLON
AND THE MARKET PROSPECTS.

DEAR SIR,—By the last mail I heard from my old friend Captain Hody Cox whose name is well known to you as the author of many interesting and valuable communications to your paper on the subject of Cinchona Cultivation and its prospects as an investment. He, like many others at home, is under the impression that we in Ceylon are flooding the home market with cinchona bark simply from choice and without regard to our own interest. Captain Cox tells me that the "Java planters are careful in regulating their shipments, it is the Ceylon planters who are ruining the London market by flooding it with supplies."

Our friends at home evidently know but little regarding the real state of things as to the future supply of cinchona bark from Ceylon. *Canker* they cannot understand or believe, and it is of no avail telling them the old story that next year will see a great falling-off. We who know all the districts where cinchona once flourished are aware that a large proportion of the bark now shipped is taken from trees dying from canker, and that a large number of planters have no cinchona trees left; it is also known that there are probably not half-a-dozen planters in Ceylon who are planting out cinchona, the reason being that it will not thrive, and especially such is the case, where cinchona has once died out from canker. All these facts tend to show that the supply of cinchona bark from Ceylon must inevitably decrease very rapidly especially after the current season. My object in writing to you now is not for the purpose of expressing my views but to send you an extract from a letter from Mr. D. Howard of Howard & Sons to Captain Cox, on the subject of the future of the cinchona market. I think that most Ceylon planters will agree with me that "the key to the situation is (not) the temper of the Ceylon planters," but our supplies are sent forward from necessities over which we have no control; we should only be too glad to hold our bark and participate in a better future were it possible.—Yours faithfully, EDWD. HAMLIN.

Extract from a letter from Mr. D. Howard of Howard & Sons:—

It is most difficult to arrive at even an approximate estimate of the stock of quinine at present existing; about 2 years ago a very large sum of money was invested in quinine by speculators and the price rose from 1s 3d to 2s for German brands. We have never been able to find out what has become of this. Immediately after this operation the German houses adopted a system of selling for forward delivery at lower prices than the actual prices of bark would justify, trusting to a fall in bark. The very fact of their doing so appeared to frighten the holders and bark was so forced on the market that their operation succeeded and they have continued same game to the present time.

The key to the situation is the temper of the Ceylon planters; they have still bark enough to ruin any market if they force it on us, either tempted by a small rise or in despair at the low prices, either of which cause will make them sell. *If they would hold back prices would at once rise*; but if the planters go on as they have done the last 2 years no good will be done till they have absolutely cleared their plantations.

If my remarks can be of any use in Ceylon, by all means send a copy. Owing to the large stock of ready made quinine on hand, the market is in the hands of speculators and merchants decline to touch the article.—Dec. 9th, 1889.

DAVIDSON'S DOWN-DRAFT AND
T SIROCCOS.

Colombo, Jan. 10th.

DEAR SIR,—Adverting to the *Home and Colonial Mail* notice of Messrs. Davidson & Co.'s Siroccos, received by this mail, and which we presume you will publish; we enclose copy of letter from Mr. J. C. Dunbar, St. Clair estate, giving the results of adding 3 air flues to his 20 tray Sirocco. We shall be obliged if you will publish the letter.—Yours faithfully,

MACKWOOD & Co., Agents for Davidson & Co.

[The extract from the *H. and C. Mail* is as follows and we append Mr. Dunbar's letter:—

DAVIDSON'S DOWN-DRAFT AND T SIROCCOS.

Messrs. Davidson & Co., of the Sirocco Works, Bel-

fast, have just erected working models on a substantial scale of their latest types of Down-draft and T "Sirocco" in Mr. Geo. Ure's convenient show-rooms on the ground floor of 132, Queen Victoria Street. These working models comprise all the most recent improvements in both these types of Sirocco, and are perfect representations in every detail of their full sized prototypes. Moreover, in the case of the Down-draft model teas of various qualities, down to the finest dust, are actually put on the trays, so that visitors may appreciate how immovably the tea remains on the trays when the full blast is turned on. The fan is worked by a treadle arrangement at the correct speed to represent conditions precisely similar to those of the full sized Sirocco.

The details of the recent valuable improvements in the construction of the stove are all easily accessible for examination, and in this connection we should add that Mr. Davidson has recently received a letter from the manager of a tea factory in India, who states that he has pulled his new Down-draft Sirocco completely to pieces after six months' constant work, for examination; and that every detail is in as good condition as on the day on which the Sirocco was first erected.

The new fan now applied to the larger sized Down-draft Sirocco is considerably larger than the original one, and, after an elaborate series of experiments, its construction has been so improved that the amount of work to be done by the larger machine is accomplished with less expenditure of power, which is a great advantage, of course, where available power is an item of importance, or where difficulties in getting the speed required for the original fan may exist.

The new T Sirocco has a hood applied to it, with a flue for leading the evaporated moisture either out of the building altogether, or, as this warmth is still efficient for withering purposes where the Blackman system of withering is in use, the flue can pass up through the floor above, and discharge the heated air into the withering room, whence the fans will, by the circulation they create, put this heat to valuable use.

This addition of a hood and flue is a most important one where the T Siroccos are employed in iron-roofed houses or in factories having a close-boarded floor immediately above the Siroccos; as in these cases the moisture-laden air from the Siroccos, having no rapid means of exit from the room, hangs over the drying tea like a wet blanket, so to speak, and prevents evaporation. This accounts for the "No. 1" Sirocco, which has a large air chimney to draw off the moisture, being so successful in such houses as above described.

We feel sure that our tea friends will be much interested by an inspection of these elaborately complete models.

St. Clair, Talawakele, Jan. 3rd.

Messrs. Mackwood & Co., Colombo.

Dear sirs,—I have put the three chimneys on to the Drying Chamber of the 20 Tray Sirocco. They are 18 inches in diameter, 10 feet long, and carried through the roof. The result has been most satisfactory. Working with a temp. of 190° to 200°, I can easily turn out 95 to 100 lb. made tea per hour counting from the time the first tray went in until the last tray came out finished. Thus: First tray on 4:45. Last tray out 10:45. Time firing 6 hours. Made tea 585 lb., average 97½. A longer run would, of course, have brought out a better average, if 30 minutes be taken off above time, the out-turn would be 106 lb. I do not notice any increased consumption of firewood. I find the quantity used varies so much with the quality of the wood, some days I have been under one pound to a pound of made tea, and other days up to 1:30 of fuel. Shall be happy to show the machine to anyone you send here.—Yours truly,

(Signed) JOSEPH C. DUNBAR.

—Ed. T. A.]

CINCHONA BARK SYNDICATE.

Colombo, January 14th.

DEAR SIR,—Enclosed we beg to hand you a letter from the Honorary Secretary of the Soekaboemische Land bouwwerenziging of Java to whom we wrote

some time ago proposing co-operation with the Syndicate here with respect to shipments of cinchona, and we shall be glad if you will make its contents public.—Yours faithfully,

DARLEY, BUTLER & Co.,
Agents for the Ceylon Cinchona Syndicate.

Soekaboemi, Dec. 28th.

Messrs. Darley, Butler & Co., Colombo.

Gentlemen,—In kind reply to your favor of 14th October 1889, we beg to state that the opinions in Java concerning the formation of a Cinchona Syndicate for Java, in co-operation with that of Ceylon, are still divided. While no few persons interested in cinchona-growing, consider such a Syndicate as a very good means to enforce the market, others consider all co-operation with Ceylon and British India as useless, because notwithstanding the low unit Java can stand the depression still for some years to come, in the expectation that in the meantime Ceylon will fall back and at last Java shall come to the front as the leading producer of cinchona bark.

While considering all discussions on the subject, our Association sent a petition to H. E. the Governor-General of Netherlands India, asking that the crop of Government cinchona bark be diminished. In reply to our petition, we received the gratifying answer, that our Government had already taken in consideration that proposal, so that we may expect, that in the future the Government gardens will produce not more than 600,000 half kilogrammes of bark a year.

On a future petition of our Association to His Excellency the Minister of Colonies in the Netherlands to raise at the auctions at Amsterdam the unit for the Government factory-bark to a minimum price of 15 cents, we might not yet receive an answer.

Within a short time we shall be glad to send you a copy of our Statistical Table for 1890 concerning the crop of Cinchona Bark in Java. You will see out of it, that notwithstanding a Cinchona Syndicate for Java has not yet been formed, already a large lot of estates are diminishing their crop or will not make a crop at all. Only some are uprooting their whole plantations, while in comparison with our table of 1889, already twelve estates have abandoned cinchona growing.

All these facts seems to us satisfactory with regard to the enforcing of the cinchona market. But still,—if our fellow-planters in the British India are joining in a British Indian Cinchona Syndicate, in co-operation with that of Ceylon,—we will try the utmost to rally the Java cinchona planters around a Java Cinchona Syndicate.—We are, gentlemen, yours faithfully,

R. A. EERHOUT, Hon. Secretary.
G. MUNDT, President.

COTTON YARN FOR CHINA.

Colombo, January 16th, 1890.

DEAR SIRS,—We have the pleasure to enclose herein a circular received by the last mail from Hongkong which will give you valuable information regarding the consumption of Indian cotton yarn in China and encouragement to the new industry of cotton spinning in Colombo.—We remain, yours faithfully,

FRAMJEE BHIKHAIJEE & CO.

Hongkong, January 1st, 1890.

Report and Tables of Imports and Exports of Indian Grey Yarn and Raw Cotton, during the year 1889, by J. Jamasjee.

We have to report a considerable expansion in the trade in Indian grey yarns during the past year, the demand and consumption showing an increase over that of 1888, as will be observed from the appended Tables. The total sales reported in Hongkong show an increase of about 15,743 bales upon those of the previous year; and the exports from Hongkong to Shanghai and Japan exceed those of the previous year by about 1,063 bales, or nearly 25 per cent. Th

total imports into China and Japan are about 52,000 bale in excess of 1888, or about 20 per cent, which may be considered satisfactory. * * * A new tariff of higher rates of freight mutually agreed upon between the P. & O., Rubattino's and Austro-Hungarian Lloyd's steamship Companies, has come into force since the commencement of the year, and the arrangement is being strictly carried out. * * * There are altogether 106 Mills working in India at the different places as below:—Mills working in the Island of Bombay 55.—In the Bombay Presidency (other than those in the Island of Bombay) 21.—In Bengal Presidency 6.—In Madras Presidency 8.—In Central India and Provinces 4.—In Hyderabad (Nizam's territory) 4.—In Oude and North West Province 5.—In Travancore 1.—In Mysore 2.—Total working 106.—In Course of Erection:—In the Island of Bombay 13.—In Bombay Presidency 1.—In Bengal Presidency 1.—In Madras Presidency 1.—Total 16.

ELECTRIC LIGHTING IN TEA FACTORIES.

Hatton, Jan. 15th.

DEAR SIR,—With reference to the letters that have been appearing in the local papers respecting the above, we enclose for your information and that of others interested, copies of letters respecting the lighting up of Lebanon Factory. —We are, dear sir, yours faithfully,

ROWN, RAE & Co.,

Sole agents for the Brush Electrical Engineering Co., Ltd.

(Copy.)

Hatton, Jan. 11th.

T. Dickson, Esq. Lebanon Estate, Madulkele.

Dear Sir,—We observe from some correspondence in the newspapers that it is stated that you have discontinued using your electric light. As sole agents for Ceylon for the Brush Electrical Engineering Co. Ltd., we would esteem it a favour if you would let us know if this is the case, and, if so, your reason for discontinuing it.—Yours faithfully,

(Signed) BROWN, RAE & Co.

Lebanon Group, Madulkele, Jan. 12th.

Dear Sir,—I have yours of the 11th inst., and hasten to answer.

My electric light is giving the greatest satisfaction, and there has not been one single hitch since it was started on Nov. 1888.

A careful record of its work has been kept, and to date it has run for 820 (eight hundred and twenty) hours, and given first-class light through it all. Beyond half-an-hour's attention every day to oil and clean, it requires no other expenditure, and practically, since erection has cost nothing but the oil consumed in lubrication.

I am writing this in my factory office by its light and a steadier or better I could not wish for.

You have my authority to write at once to the local papers and contradict the rumour. I have been troubled recently by repetitions of the same rumour, and wonder who was foolish enough to start it.—Yours faithfully,

(Signed) T. DICKSON.

CATTLE BREEDING.

DEAR SIR,—From my experience of hackery bulls in and around Colombo, and their speed and powers of endurance, I had long ago come to the conclusion that they are usually unable to go at one stretch more than a distance of 12 miles in 3½ to 4 hours. To my surprise only a few days ago I travelled from 3 p. m. till 11 p. m. a distance of 30 miles in a hackery drawn by a cross-bred bull. On my complaining to the driver of his cruelty to this fine animal he said that it was a very hardy animal frequently travelling 15 to 30 miles a day to and from Colocabo. He mentioned another fine well-shaped cross-bred black bull which had smashed its hackery the previous day against a tree; having got frightened after trotting 3 miles at some noise. To avoid breaking my neck I hastily jumped out of the hackery.

This bull was as spirited as a young Australian horse, though he had travelled the previous day a distance of 50 miles, I am informed. Well I daresay there are many more such hardy animals in the Negombo district; but I am afraid such animals are seldom or never to be found in and around Colombo where there is a great demand for them at present when many well-to-do people who drove about in horse-carriages are using decent hackeries. It strikes me that it would be well for the natives to try to rear bulls of this hardy nature and improve the stock of the island cattle.—Yours truly,

PRO BONO PUBLICO.

[This reminds us of the wonderful number of bullock hackeries which now find employment at the various railway stations. This was not anticipated by the bullock bandymen who intreated the late Mr. De Soysa not to join the Europeans in ruining them by promoting a seaside railway. ED.]

QUALITY OF TIMBER-TREES.

Jan. 17th.

DEAR SIR,—In your interesting articles headed "Railway Sleepers," I see you make mention of "Timbiri" as good for spars and as having been given a trial for use as sleepers. This tree is very abundant in the Chilaw districts, but is looked upon as worthless timber "for even fire-wood." The juice of the fruit is, however, very commonly used for preserving fishing nets and in caulking canoes. I have never seen further use made of the tree,* and should be glad to hear that the timber is of any value. You also mention *Pleurostyliia wightii* called by the Tamils here "Peiyaru" (not Pasari); a very valuable wood for house building, but, as far as my experience goes, an inferior kind for outdoor work. The grand "Palu" seems to be the best, all round, for use as sleepers, as it is not only hard, even-grained and not liable to crack under exposure, but it is also one of our commonest timber trees throughout the drier parts of the island. Apologizing for trespassing on your valuable space,—Yours faithfully,

GEORGE D. MILLER.

[All such communications are welcome. Of course, in writing, we gave the best information available, relying specially on the opinions of members of the Forest Department. But even they are not agreed in every case, and hence the great value of the series of trials now instituted. There can be no doubt that age at which felled and the period and mode of seasoning have much to do with the qualities of timber. Specimens even of the best timbers, if immature or imperfectly seasoned, are sure to be condemned.—ED.]

GREEN TEAS MANUFACTURED ON KINTYRE, MASKELIYA.

Colombo, 21st January 1890.

DEAR SIR,—Your planting readers will, doubtless, be interested in learning that Mr. H. Drummond Deane of Kintyre has been most successful lately in the manufacture of green teas made by a machine of his own invention which he is patenting.

I know nothing of the machine itself, nor is it within my province, even if I did, to write on the subject until Mr. Deane has secured his patent, but I can report as to the quality of the teas produced by the machine.

The samples submitted to me are without exception the only green teas that have come under my notice in Ceylon that are all that green teas

* The astringent bark is used for sores and ulcers.—ED. T. A.

should be. By Mr. Deane's process the green leaf does not ferment in the least during the rolling. There is consequently no oxidization, a result not obtainable by firing the green leaf immediately after it comes out of the roller. The infused leaf is therefore of a *uniformly yellow* greenish colour, as it should be, and the liquors of a pale, pure, pungent Japan character, with all the characteristics of fine flavoured green tea.

Mr. Deane has at last overcome the difficulty he for a long time experienced, of obtaining and retaining the requisite wiry twist of leaf.

I consider there is a great future for Ceylon green teas of the quality and character lately produced by Mr. Deane, and I am decidedly of the opinion that when these teas are made in sufficient quality, and become known, that they will, in time, drive the China article out of consumption, just in the same way as Indian and Ceylon black teas have, and are still doing.

These are the teas that the Ceylon Planters' American Tea Company would do well to begin the campaign with in America,—as the taste is already established there for these unfermented teas, by the long use of China and Japan greens. Americans will then have an opportunity of judging of the superior quality of pure Ceylon greens as compared with the faced China teas of the *same class*.

Mr. Deane may possibly publish my reports as soon as he has obtained his patent, which I hope and believe will prove as great a success as the teas are, made by it.—Yours faithfully,

F. F. STREET.

NEURALGIA.

NEURALGIA, or "nerve-pain," may occur in any part of the body, but the commonest variety is that which attacks the face, and is known as tic or tic-douloureux. The pain is usually very intense, and may keep the patient awake many nights in succession. When the pain attacks the arm it is generally known as ulnar neuralgia, whilst the same pain attacking the sciatic nerve of the leg is known as sciatica. Attacks from neuralgia may persist for many years, the intervals in some cases being long, and in others short. Much may be done by timely care and attention to ward off attacks of neuralgia. Diet (regular and homely), exercise, a sufficient amount of sleep, and the avoidance of badly-ventilated rooms, are all points to be attended to.

One of the best remedies to be referred to in cases of neuralgia is quinine, this drug being specially indicated when the complaint depends either directly or indirectly on the presence of ague. One of the Quinine Tablets should be taken every three hours, until relief from the pain is obtained. When the patient is pale, and the condition of the blood is below par, Dialysed Iron (Wyeth) may be given for a few days to begin with. Another good remedy is chloride of ammonium, but it is essential that it should be taken in fairly large doses, two or three of the ten-grain tablets every four hours. Arsenic, sometimes, is highly beneficial, and should be given in the form of the Tablet Tablets, one-hundredth grain, one three times a day.

When the pain occurs in the limbs, benefit may be derived from the application of a Menthol Plaster. Blisters often do much good, and other counter-irritants, as they are called, such as mustard and iodine, are useful. Treatment by means of electricity may have to be resorted to, under medical advice.—*Health*, London.

A COMPANY has been floated in London with a capital of £150,000, to carry on the business of indigo planters and manufacturers of, and dealers in indigo, and to acquire and turn to account certain inventions connected with improvement in the manufacture of indigo of Mr. E. C. Schrottky, of Dresden and Mozufferpore, Tirhoot. Mr. Schrottky, who has devoted considerable attention to the subject, has taken out in India patents for various processes in connection with indigo manufacture. These will be acquired by the new Company.—*Madras Mail*, Jan. 13th.

COCONUTS IN THE United States, are used for numerous purposes, as confections, &c. We find an advertisement in the *American Grocer* to the following effect:—

Dunham's Concentrated Shred Coconut. Put up in fancy tin flower pots, decorated in blue, pink and gold bronzes. This is the handsomest package ever used, and is useful as well as highly ornamental. The shred coconut has a light, snowy appearance, which makes it far preferable to the meat of the fresh nut for decorating cakes and pastry. It is also put up in extra large quarter and half-pound paper packages which retail at 10 and 20 cent each.

THE CONSUMPTION OF COFFEE IN AMERICA is apparently steady, not advancing, as formerly, about eight to ten per cent annually. This may be due to the high prices of the past three years, as compared with the low prices ruling from 1880 to and through 1886, since which time the cost of the article has nearly doubled, leading to a more generous use of coffee mixtures. The trade for this year is about abreast of the same time last year, the monthly consumption showing an average of 18,106 tons for eleven months of 1889, against 18,015 tons for the corresponding period in 1888, a difference of only 91 tons per month. The daily consumption of coffee absorbs about 600 tons or 10,200 bags.—*American Grocer*, Dec. 11th.

THE TRADE OF COLOMBIA.—A report from the British Consul at Bogotá, on the trade of Colombia, which has just been issued contains statistical tables which represent the labour of several months of the German Minister of Colombia and his secretary, who have compiled them from a mass of undigested materials in the possession of the statistical department. The total imports in 1887 amounted to £859,269, and the exports to £1,396,322; but in 1888 they amounted to £1,064,225 and £1,666,818 respectively. The increase is due to internal tranquillity and the prospects of order being maintained. Colombia trades mainly with four countries—Great Britain, France, Germany, and the United States. In 1888 their respective shares in the import trade were 49, 21, 13, and 12 per cent., and in exports 34, 10, 12, and 40 per cent. The United States take nearly all the Colombian coffee, cacao, and timber; Great Britain takes nearly all the cinchona and all the ores. The decrease in the export of the latter has caused a slight decline in the British share of the export trade. No gold has recently been coined. A considerable sum has been exported, and much is locked up, so that practically no specie at all is now current. The limit of the bank-note circulation allowed by law has been almost reached, and is not sufficient for the requirements of the country, especially as the notes of those banks for which the Government was responsible have been rapidly called in. One railway has been completed, and there is no abatement of the great activity in all classes of mining operations. The chief ports, in order of importance, are Barrandulla, Cartagena, Cucuta, Buenaventura, and Tumaco.—*London Times*,

CEYLON UP-COUNTRY PLANTING REPORT.

THE INGENUITY OF THE THIEVING NATIVE AND CACAO STEALING—LIBERIAN COFFEE PROSPECTS—PEPPER AND NUTMEGS—SHEEP-REARING IN UVA—WEATHER AND CROPS.

Jan. 20th.

The ingenuity of the thieving native is astonishing. If directed in proper channels, what a career there would be for some of those fellows whose lives seem to consist of preying on the public, either inside or outside of the jails, and whose wits are sharpened to such an extent as almost to demand admiration. The latest of their dodges which I have heard of is connected with that fruitful and remunerative branch of their service, cacao stealing. We have heard of them using the young cacao pods for curry; but as the market for this must be limited to the demands of their own stomachs, or the appetite of their most intimate friends, it is pretty clear that in this department of their art there is very little scope, and a glut soon takes place. It is the ripe nib that has charms and potentialities which enlarge with the advance of price; and when cacao touches R60 a cwt. in the local market the wits of the Sinhalese raiders are then at their best. Whatever has been carried off must, if at all possible, be utilized. With the ripe pods there is no difficulty, if they alone can be gathered; but for trade reasons it is not always possible to adhere to such everyday distinctions, nor be so very particular. Of course there is more safety in selecting naught but ripe fruit, for if caught and brought up before the magistrate, this act only involves imprisonment; whereas to be in possession of unripe pods might be rewarded with stripes over and above. Nevertheless, when helping themselves to the fruits of another man's labour, without his knowledge or leave, they are not too particular; and so it comes about that when the results of a raid into a cacao garden are examined a number of half and three-quarter ripe fruits have to be disposed of. It is in working up this to meet the local market and the local demand that the ingenuity of the raider comes out. As it is difficult to get unripe cacao to separate nib from nib, this is managed by boiling the pod; and as this process is not conducive to the fine red colour which buyers desire, the necessary tint is got up by the use of annatto! This hand-made article when mixed with the real thing in not too large proportions will pass muster, and be even unsuspected.

Liberian Coffee is having its "ups" at present. The high price of coffee is causing more attention to be paid to the various varieties of the fragrant berry, and the despised Liberian is evidently not to be neglected. One man who has a small acreage of this tree was telling me that he was more than satisfied with the crop just gathered, as he had had a return equal to R1 a tree. In the old days of Arabian coffee half of this was deemed a fair average price when land was taken, and if Liberian is to do anything like what my informant has netted, this despised product has clearly a future before it.

Those who have gone in for Pepper speak hopefully of it as an adjunct to other products. The local price of R14 a bushel is not to be despised; and when it is known that to collect a bushel of this spice involves the labour of only seven coolies, it is evident enough that there is a good margin for the normal fluctuations of the market, and a fair profit to the grower.

Nutmeg culture is being prosecuted in a quiet way, and the demand for seed is steady enough. In the lowcountry I hear of several places where the growth is very encouraging, and

the prospects good. An experiment of growing nutmegs in the shade, and by themselves alone, is being tried; the undergrowth of the jungle having been removed, and the big trees left standing. It will be interesting to learn by-and-by how this works out; the general idea being to regard the nutmeg as one of those things which will in time take the place of what already occupies the ground, and pays the way. For the nutmeg to rest solely on its own resources may be an interesting experiment, but it will be some years before it is a paying one. The happy owner will however have prolonged that blessed season of hope, which all cultivators who start from the beginning enjoy—his only assured return—and in that may find his reward. Nutmegs sell easily in the local market at better rates than ever was got before, and mace fetches from R1.25 to R1.50 a lb.

An experiment in Sheep-rearing on an extensive scale is likely soon to be tried on the patanas of Uva: an Australian squatter being the man to be first in the field. If this is a success there should be good mutton to be got, and goats' flesh which goes by that name will be a thing of the past. To part with it should not cost any of us a sigh.

The showery Weather which we have been enjoying for a week now has done a world of good. Coffee blossom is in spike—strong and healthy—when the trees are at all in good health! Tea is also waking up, and prospect of flushes fine. Rice unfortunately like Exchange keeps high; and, if one were to believe the chetty, Southern India is on the eve of a season of dire destitution, there being neither rain nor crops in the land. Newspaper reports to the contrary he regards as lying tales, as leanness in the land helps him to a fat price for rice. PEPPERCOORN.

IMPORTANT MACHINERY CASE IN THE KANDY COURT.

BROWN, RAE & Co. v. E. H. SKRINE.

Kandy, Jan. 21st.

A case of some importance comes on for trial before Judge Lawrie in the Kandy Court tomorrow (22nd inst.) involving questions of engineering skill, and for which many engineers from Colombo and upcountry are expected to attend. The plaintiffs in the case, Messrs. Brown, Rae & Co. of Hatton, have summoned Mr. E. H. Skrine of Osborne estate, Dikoya, for the recovery of R1,949.16 value of goods, articles and merchandise supplied to him, and for the Osborne estate, and for erecting on the said estate a water motor and supplying all the requisite materials. The defendant, admitting that the plaintiffs, between June 1886 and April 1887, supplied goods, states that certain items are incorrect, and denies that they did erect, as alleged, on Osborne estate a water motor, or supply all the materials and labour requisite for the erection of the same. The defendant sets out, in detail, the agreement with plaintiffs, and states that the defendant and his servants executed all works which they had undertaken to carry out under the supervision and to the satisfaction of the plaintiffs and their engineers and assistants, and the plaintiffs accepting the said work proceeded in Nov. 1886 to attempt to erect the motor, which work they should have completed within at most a fortnight thereafter, and continued their said attempts until April 1887, with the result that in breach of their said agreement they never did properly completely erect the said motor and bring the same into proper working order, but so mal-erected and injured the motor as to render it inefficient, useless and valueless to the defendant for the purpose he had purchased it; and the defendant avers that the failure to erect the motor and the mal-erection thereof and injury thereto were due to the want of constant and due supervision by qualified European engineers

which the plaintiffs had promised to give; to the errors and defects in construction of works and fitting and adjustment of the parts of the motor; and to the want of due care and skill and the disregard of the plans and instructions given by the makers of the motor shown by the plaintiffs in the attempted erection and working of the machine. In reconvention defendant claims R4,211, damages, as well for their breach of agreement as for the loss suffered by the defendant by malerection, injury to and consequent inefficiency of the machine, cost of labour, works constructed, materials utilized for its attempted erection and of surveys held thereon and expenses by defendant, loss of profits, and greater cost of carrying on tea-making in his factory. There is also a claim in reconvention of R50 in respect of the erection of a sifter said to have been "Bailey and Thomson's sifter," but afterwards found to be one of the plaintiffs' own manufacture.

Plaintiffs in their replication specially deny that their account is incorrect and persist in their charges; as to the claim in reconvention they say that the statement as contained on the answer, of the circumstances under which the water motor was ordered, is contrary to fact; and as regards the erection of the motor that the work which they contracted to perform was only to fit up the motor which was sent from England in pieces, and to erect the gearing necessary to connect the motor with the machinery in defendant's factory. Plaintiffs deny that they agreed to supply any material for the work or to bring the machine into what defendant might consider "proper working order," or that they undertook the supervision of any masonry work or any responsibility whatever as regards such work; or that such work was done to their satisfaction. They deny further that they failed properly to erect the motor or that they malerectioned or injured it, or that there was any want of proper and due supervision of qualified European engineers or any want of due care and skill or disregard of plans and instructions given by the makers.

The witness on the plaintiffs' list are Mr. G. F. Deane of Dmbetenne, Mr. George Greig of Laxapana, Mr. Arthur Anson of Osborne, Mr. David Michie of St. Sebastian Mills, Colombo, Mr. C. D. Pattulo of the Colombo Commercial Company, Mr. D. J. Sarasinhe of Walker & Co., Kandy, Mr. R. J. Farquharson of Lower Haloya, Mr. Harcourt Skrine of Osborne estate, and Mr. John Brown of Slave Island. Those on defendants' list are Mr. James Brown of Hatton, Mr. A. J. Pearson, Mr. W. D. Smith, Mr. C. A. Hutson and Mr. A. Garrean.

There was a proposal to refer the questions arising in the case to arbitrators, but this was objected to by one of the parties.

THE FIBRE INDUSTRY.

A process has been invented at Peabody, Mass, for bleaching the ramie fibre so that it can be worked in the present cotton machinery, and at the Toppan Manufacturing works in that town may be seen the first importation of ramie grass for manufacturing purposes. The works have orders ahead for a large amount of the new material, one mill alone calling for the equal of 10,000 pieces of dress goods. The discovery bids fair to open a new industry in the South in the cultivation of this heretofore neglected grass. The works are being enlarged by a 40 x 20 addition, two stories in height.

A decorticator has been tested at Bristol, Pa., within a few days that will interest the people of the South. The machine was intended principally to separate the fibres of the ramie plant from the wood. The first test was made by running a batch of dry stalks of the ramie plant, which had been brought from North Carolina, through the machine. A quantity of jute stalks were then put through, and finally the green stalks grown on a neighbouring farm. The machine did

its work in a most satisfactory manner, leaving the fibres clean and free from wood. The fibre was placed in a chemical preparation, after being taken from the machine, for the purpose of dissolving the gum. It was steamed two hours, after which it was placed in the bleaching vat. After bleaching for about thirty minutes it was taken out and dried, the entire process of transforming the green stalks into delicate fibre ready for the spinner having occupied less than three hours.—*American Exporter.*

NOTES ON PRODUCE AND FINANCE.

The delay in the delivery of tea is causing some members of the tea trade to express themselves vigorously upon the subject. One correspondent in a long letter, asks: How long is every tea dealer in the United Kingdom to be inconvenienced by such conduct?

Epitomised, this correspondent's suggestions are:—

1. All weights to be ready for delivery at the time of making the sale. The undelivered whole or part to be subject to a reduction of 1d per lb., but if overdue seven working days 2d per lb.—buyer always having the option of refusing absolutely any undelivered weights.

2. All catalogues of teas for auction to be issued as follows:—For Monday's sale, previous Thursday at latest; for Tuesday, previous Friday; Wednesday, previous Saturday; Thursday, previous Monday; Friday, previous Tuesday; and Saturday, previous Wednesday.

3. No catalogue to be issued until the samples are actually laid down ready in the warehouse show room.—*H. & C. Mail, Jan. 3rd.*

COCONUTS:

REPORT BY THE SELECT COMMITTEE OF THE LEGISLATIVE COUNCIL STRAITS ON THE COCONUT TREES RESERVATION BILL.

(From the *Straits Times*.)

PENANG, Dec. 23rd, 1889.

SIR,—We have the honour to report upon the Coconut Trees Preservation Bill as follows:—

From the information we have received, and the opinion expressed by many experienced planters, we find that section 2, while too drastic in one respect is not sufficiently comprehensive. There seems to be no reason why trees attacked by beetles should be destroyed. All the evidence we have gathered goes to show that such trees, even when severely attacked, recover if the beetles are removed, and the trees properly manured. On the other hand, a tree that dies no matter from what cause, is certain to become, if allowed to stand, a breeding place for beetles. A large number of coconut trees are annually killed by lightning, and these trees appear to be favourite places for beetles to breed in. Instead, therefore, of the present section, which necessitates the destruction of all trees attacked by beetles, and says nothing about those that have died from other causes—though we are aware that section 4 includes the latter—we would suggest a section to this effect.

"It shall be the duty of the owner or person in charge of every coconut tree which is dead to cut it down forthwith, and destroy all the beetles, and all eggs and larvæ therein, and to consume the tree with fire, or bury it in the ground at a depth of no less than two feet."

Our reason for suggesting the burial of dead trees as an alternative to fire is the enormous difficulty—almost impossibility—of burning coconut trees to ashes. If only charred they would still be liable, after decay had set in, to become breeding places for beetles, whereas, if cut down at once and buried, there would be no chance of beetles breeding in them. Indeed it is only after a tree has been dead for a considerable time that it becomes a breeding place. Trees newly dead are seldom found to have eggs in them. We of course, refer here to the black beetle. The habits

of the red beetle are different, the grub, and not the beetle, in the case of the red beetle, being the destroyer. The red beetle, however, is so rare here that some experienced planters have never seen it, and all agree that for practical purposes it is unnecessary to consider it.

To section 3, we would suggest an addition. The different planters we have consulted are of opinion that the District Officer is more likely to learn and see for himself, when trees are not attended to, than the Director of Gardens and Forests, and we would, therefore, suggest after the words "Director of Gardens and Forests" the words "or the District Officer or such other person or persons as the Governor may from time to time appoint."

Section 4 is, in some respects, the most important in the proposed Ordinance. Manure and rubbish heaps are, no doubt, great beetle breeding places, and, therefore, it is necessary to deal with them; but inasmuch as manure is required for agricultural purposes, and other favourite breeding material for other trades, the matter must be dealt with in such a manner as not to injure or interfere unnecessarily with agricultural or other interests. We, therefore, recommend that while the public generally shall not be allowed to keep on their premises any matter likely to harbour or become breeding places for beetles, those engaged in undertakings requiring the use of manure or other matter in which beetles are likely to breed, shall be allowed to keep it on their premises, provided they take every precaution for preventing the breeding of beetles. The best plan for carrying this out effectively appears to us to be the granting of licenses. Every one whose calling requires the use of material likely to harbour beetles, should obtain a license for keeping such material on his premises. Any one keeping such material without a license should at once be prosecuted. Those obtaining licenses and not fulfilling the conditions on which they are granted should, of course, also be liable to prosecution. From the information we have received, such precautions present no difficulty. In the case of manure and rubbish heaps, a little care and attention, the frequent turning over of the heaps to a depth of a couple of feet or so, and the destruction of all the larvae found therein, are all the precautions that are necessary. But there is another important matter. Since the introduction of Indian cattle here, which require straw for fodder, beetles have increased enormously, and some planters are of opinion that the stacking of paddy straw is the chief cause of this increase. The beetles breed at the bottom of the stacks close to and in the ground. To prevent this all that appears to be necessary is to stack the straw on trestles about a foot or so from the ground. We would, therefore, suggest, instead of section 4, two sections to the following effect:—

"If any person keeps on his premises, except under the conditions hereinafter contained, dead coconut trees or stumps or coconut timber, rubbish heaps or other accumulations of dung, vegetable refuse or other matter which would be likely to harbour or become breeding places for the said beetles, and neglects or refuses to remove and destroy the same when required so to do by the Director of Gardens and Forests, or the District Officer or such other person or persons as the Governor may from time to time appoint, he shall be liable to a fine not exceeding \$25, and the said Director or District Officer or person appointed by the Governor, may cause such trees, stumps, timber, rubbish heaps or other accumulations to be removed or destroyed and may recover the cost of such removal or destruction from the defaulter in the Court of Requests."

"Persons engaged in planting or gardening or in other trades or callings requiring the use of cattle manure, vegetable refuse, straw or other matter in which beetles are likely to breed, shall apply to the officer who shall be appointed by the Governor for the purpose, for a license to keep such cattle manure, vegetable refuse, straw or other matter on their premises and, on obtaining a license, shall take such means for preventing the breeding of beetles in the cattle manure, vegetable refuse straw or other matter as the

officer appointed by the Governor shall in writing from time to time direct, and any person holding a license who refuses or neglects to carry out such measures within a reasonable time shall be liable to all penalties under the preceding section as though no license had been obtained by him."

It will be noticed that, in the first of the two sections we suggest to take the place of section 4, we add the words suggested as an addition to section 3, namely, "or the District Officer or such other person or persons as the Governor may from time to time appoint"; and as we consider it most important that the District Officer as well as the Officers of the Gardens and Forest Department should have every facility for enforcing the regulations and preventing the breeding of beetles, we would recommend an addition to section 5—which would become section 6—giving them similar powers, and a further addition authorising both Officers of the Gardens and Forest Department and District Officers to inspect stables, cow-houses, &c. even when not near a coconut plantation. This would render a large portion of the section unnecessary. In fact we would suggest that it be altered to read as follows:—

"All Officers of the Gardens and Forest Department and the District Officers and their assistants and such other persons as the Governor may appoint for the purpose shall have access at all reasonable times into and upon all lands, stables, cow-houses, sugar factories, rice mills, tanneries, or other places within the Colony wherein beetles are likely to breed, for the purpose of discovering whether there are thereon any such things as in the last two preceding sections are referred to."

The reason why we suggest such a comprehensive section is this. We are told that the beetles fly miles away from the places where they breed to the coconut plantations, that the stables both in towns and in the suburbs are the sources whence myriads of the beetles come, and that, without these being supervised, the pest cannot be so effectively dealt with as is desirable.

With the modifications and additions that we have suggested, we believe section 6 to be unnecessary. Trees would only be destroyed when utterly valueless, and there can be no question of compensation for an utterly valueless and, moreover, dangerous thing. In cases where the owner of a dead coconut tree may be in needy circumstances, the most that he can fairly look to the Government to do is to cut down and burn or bury the tree without charging him with the expenses incurred.—We have, &c.,

J. M. B. VERMONT,
J. Y. KENNEDY.

THE COCONUT TREES BILL.

(From the *Straits Times*, Jan. 11th.)

The report on the Coconut Trees Bill published in our issue of yesterday contains several valuable suggestions derived no doubt from discussions with the principle coconut planters in Province Wellesley. The chief of these suggestions are that dead trees, whether diseased are not, shall be cut down and buried, and that the district officers shall be made inspectors under the Act. It is also proposed that persons whose business requires them to store quantities of manure or other decaying matter shall require to obtain a license for doing so, and that they shall be bound so to keep that matter as to render it less liable than at present to be a breeding place for coconut beetles. So far we are entirely with Mr. Vermont and Mr. Kennedy in their conclusions, but there is one point on which we are compelled to differ from them. While recognising the merits of their valuable report, we are sorry that they avoid any discussion on the habits of the red beetle, upon the plea that the existence of that beetle is so very rare that it need not be taken into account. Now, as a matter of fact, in the island of Singapore at all events, the red beetle is by no means so very rare as Penang planters seem to imply, but on the contrary it may be frequently seen in coconut plantations. Still it is to be admitted that it is far less numerous than the black beetle, but on the other hand it is very much more dangerous. It seems that the

members for Penang and Province Wellesley and their planter friends are making the mistake which is common to planters in all parts of the world, and which frequently leads to numerous losses and from time to time to the annihilation of planting industry. That is to say they decline to take any measures against a pest until that pest has become so considerable that it cannot be readily overcome. The red beetle may be rare, but it has destructive proclivities far in excess of those of the other, and it should be remembered that we are so little conversant with the habits of insect life that we have no means of providing against a possible large increase in numbers. The experience of all those insect pests is that suddenly, and for no apparent reason, they are liable to largely increase in numbers; and this being, so to ignore their existence would be foolish, at a time when the matter is engaging our attention. It is true that Province Wellesley is chiefly interested in this question, but there are hundreds of small plantations scattered around this neighbourhood, the owners of which by the Penang proposal are to be compelled to take precautions only against an enemy that is common to all, while they are, as far as laws go, to be utterly indifferent, if they choose, in the case of a more deadly, though it may be less frequent, danger.

AN ACID-PROOF PAINT.

A successful experiment is reported to have been made recently at the laboratory of the Joseph Dixon Crucible Company, in Jersey City, N. J. A piece of iron ten inches long, two inches wide, and one-sixteenth of an inch thick was used, and one-half of its surface painted with silica-graphite paint, while the other half was left unpainted. It was suspended for several days in a bath of diluted sulphuric acid. The bath was much stronger than any sulphur water met with in mining. On taking the iron from the bath the unpainted part was found eaten off to about one-half its original bulk. The painted part did not sustain even the slightest blemish, thus apparently proving the ability of this paint to withstand sulphuric acid, and demonstrating its usefulness where iron piping is laid in acid water, such as is sometimes met with in mines containing pyrite or other sulphides which, under certain conditions produce acid water in the form of sulphate solutions, resulting from the decomposition of the sulphide minerals.—*Engineering and Mining Journal*. [As there can be no doubt that the graphite in the paint came from Ceylon, we submit that the paint, which is we believe fire-proof, ought to be tried on our tea factories.—Ed.]

THE GEMMING SYNDICATES AT WORK IN SABARAGAMUWA.

[FROM OUR GEMMING CORRESPONDENT.]

Jan. 22nd.

The Gemming Syndicates are hard at work exploring and prospecting throughout this district, principally on private lands, as the Government does not seem to give any encouragement to do anything on Crown Lands. For what reason no one seems to know. All licenses have been refused for some time back to natives to gem on Crown Lands. The conditions laid down by Government for gemming on Crown Lands are so objectionable, I hear, that no Company cares to have anything to do with them. Some of these conditions I may just mention for the edification of the general public:—1st. All timber that is damaged or made use of has to be paid for at a price fixed according to quality. 2nd. All mines or pits have to be filled in before abandonment. 3rd. No streams or watercourses are to be turned, &c. &c. And last but not least—fabulous prices are expected for the lease or purchase of Crown Lands. So I suppose the Crown will have to keep them and allow the natives to carry on (as hitherto) illicit gemming, which has become much more prevalent since licenses have been refused. When the British public are offering capital to any extent for the pur-

pose of developing our Gem Mining Industry and are now prepared to unearth the hidden treasures of our would-be backward colony, why should the Government discourage and frustrate the attempts made to introduce the much needed British capital? Look at the liberty and encouragement extended to prospectors to look for precious metals &c. on Crown Land in any other colony. Why off they go prospecting all over Crown property and when they find gold or other metals they peg off their claim, and when worked, should it prove a success then and not till then does the Government step in and demand its royalty. I believe this is the way in most of our new Colonies, and in that liberal policy success is warranted. Now, here we are scheming all sorts of ways and means to make revenue out of a concern before it is started by imposing a tax to be recovered from all landowners who seek for gems. Perhaps it may be said that we are not at the prospecting stage, but I maintain that we are and should get every encouragement from Government to develop the hidden treasures of our Island. I could say much more on the subject, but I am too disgusted with it for the present. Look for instance at the encouragement the late Mr. Home got when he wanted to search for gold, *re* your book on Gold and Gems in Ceylon.

THE NILAMBE DISTRICT was in its early days one of the richest coffee producing divisions in the country; it included over 2,500 acres of coffee giving 16,000 to 20,000 cwt. each year. For the current season, all the coffee remaining is expected to yield 70 cwt. of crop!; but then the old district is to give 700,000 lb. of tea; 100,000 lb. cinchona bark; 15,000 lb. cardamoms and 50 cwt. of cocoa—all this going far to make up for the deficiency in coffee, especially in view of the greater economy now exercised in management of plantations.

TAMBRACHERY ESTATES.—The eighth annual general meeting of the Tambracherry Estates Company, Limited, was held on Monday at the Cannon Street Hotel, E.C., under the presidency of Mr. James Labouchere. The chairman, in moving the adoption of the reports and accounts, said the company had done fairly well; they had paid their expenses, and had something to the good, but, as in the two previous seasons, that which they had to the good was not good enough to enable them to pay a dividend. On the other hand, they were left as they were as regarded the value of the estates, and for success in the future they must look to what prices, crops, and seasons would do for them. The coffee crop, which was estimated to realise certainly over one hundred tons, had only realised eighty-six tons; on the other hand, prices had been excellent, and what they had sold had realised £7,771. The report was adopted.—*H. and C. Mail*.

THE CEYLON TOBACCO COMPANY AMALGAMATES WITH THE GERMAN COMPANY.—We are glad to say that arrangements have been made whereby the Ceylon Tobacco Company, Ltd., takes over all the land purchased by what has been called the German Syndicate for the cultivation of tobacco, the latter taking payment solely in full paid up shares of the Company. Messrs. T. N. Christie, O. S. Armstrong, and Hugh Fraser have just concluded a careful inspection and valuation of the land purchased by Mr. Frelz Meyer, and have concluded the arrangements for taking over the land with his Mr. Schappe, who holds his power of attorney. This practically means the amalgamation of the two Companies, leaving the capital of the Ceylon Tobacco Company free to work the land. Mr. J. K. Ingleton having an agreement with the German Syndicate, the Tobacco Company takes it over, and Mr. Ingleton will now reside on the Matale property with full charge over all the land of the amalgamated Company. Mr. P. W. Keir will reside on the Kurunegala land, working under Mr. Ingleton and, after one or two crops of tobacco have been taken off the land, tea will be planted in Matale and coconuts in Kurunegala. We wish the Company all success.—*Local "Times,"*

“INDIA AND CEYLON INSECT PESTS.”*

(Third Notice.)

THE CEDRELA TOONA MOTH—BAMBOO INSECT—THE MANGO WEEVIL—THE BOLLWORM.

We give, as of local as well as general interest, the description of

9.—THE CEDRELA TOONA MOTH.
Magiria robusta, Moore.

Plate III, fig. 3, a moth, b pupa, c larva; all natural size.

Specimens of this pest have been received from Mr. E. E. Green, of Ceylon, who writes that the larvæ damage *Cedrela toona* trees which are cultivated on the coffee estates for firewood and timber-supply.

Mr. Green writes † :—
“The larvæ appear to affect the new growth only, living on the succulent tops and devouring the pith of the stems and leaf stalks. The effect of the borer is to kill off the leading shoot, after which numerous adventitious shoots appear below the point of injury. The presence of the borer may be detected by the accumulation of the excreta at the mouth of the tunnel where they are fixed and woven together with silk by the larva.”

The following extract is taken from a paper‡ signed T. S. G. that appeared in the *Indian Forester* in 1876, and which appears to apply to the same species :—

“The insect almost yearly attacks the young shoots of the toon tree, boring its way along the pith which it seems to live upon, and leaving behind it an unsightly looking mass of transparent gummy exudation. The larvæ is white with black and yellow spots. . . . It attacks trees both in plantations and in the forests, and prefers those about three feet in height and of strong growth. It seems to attack, however, more particularly those trees which grow in cleared lad or near roads, while others growing close by, in grass or with other trees, have been comparatively unharmed.”

Some larvæ of this insects have been sent to the Museum by the Sub-divisional Officer of Alipur, Western Coors, who found them in the wood of some young mahogany trees. In this case, whowever, it seems probable that most of the injury was done by some Coleopterous larvæ that were also found in considerable numbers.

Mr. Moore, in his *Lepidoptera of Ceylon*, Vol. III, p. 366, quotes from Thwaites that the larvæ feed within the branchlets of mahogany.

From the Director of the Forest School, Dehra Dun, have been received specimens of what appears to be the caterpillar of this moth, found by the Forest Ranger of Nilambur, Madras, “attacking the succulent branches of experimental mahogany plants.”

Caterpillars of this insect were also obtained from the Museum of the Forest School, Dehra Dun, where they were marked as having, in June 1886, proved destructive to the seed§ of *Cedrela toona*.

Mr. Moore, in his *Lepidoptera of Ceylon*, classes the insect in the family Phycitida.

The following is his description :—

“Female. Fore wing, pale ochreous-brown, very thickly speckled with cinereous-white along the anterior border, and sparsely speckled with black scales along the posterior border; all the veins, excepting the submedian, lined with black, crossed by a discal, denticulated, whitish-speckled line; marginal points white; hind wing, ochreous-white, semi-hyaline, rightly opalescent, with a pale ochreous-brown slender marginal border; cilia white, with a brown inner line. Body, palpi and legs ochreous-brown: sides of collar, tegulae, and base of abdomen with a cluster of black speckles; fore legs above dark-brown, with white bands; middle and hind legs whitish speckled; a brown band on middle tibiae, and whitish bands on the tarsi. Expanse of the female one and three-tenths of an inch.”

“Pupa dark purple-brown, enclosed within an elongated slight silken cocoon attached to the stem of the food-plant.

Mr. Green describes the larva as follows :—

“Colour dull purple. Head black—second and thirteenth segments each with two black corneous dorsal plates. Other segments each with a transverse series of six raised black corneous spots, with a second row of two similar spots on each of the fifth to the twelfth segments. A small dull orange-coloured lateral spot on second and fifth to twelfth segments, Spins a compact whitish cocoon.”

The larvæ reared by Mr. Green were full fed about the end of September, the moths appearing towards the end of October.

Cedrela toona and Mahogany, allied species, are badly attacked at Peradeniya, but at 4,000 to 6,000 feet, the red-foliaged toon has in our experience escaped. The white toon, on the other hand specially liable to attack, while its branches and the tops of trees are broken by wind.

Clothes moths are noticed, and naphthaline as a remedy. The Bengal rice Hispa (*Hispa anescens*, Baly) is prevalent all over India, but is not mentioned in connection with Ceylon. We quote as follows :—

From the reports that have been received, it seems that the pest appears often in vast numbers during the rains when the rice has just been planted out and is still young and tender, the insects feeding on the parenchyma of the leaves and stalks, leaving the fibre exposed, so as to give the plants a white and withered appearance. The insect pupates on the plant.

The effect of the pest would seem to be to stunt and weaken the plants and cause them to yield but a small crop. The rice is apparently in no case completely destroyed by the insect, but the outturn may be reduced by from twelve to fifty per cent.

No very definite information has yet been received with regard to remedies: the only two that are mentioned as adopted by the cultivators, being the smoking the insects out of the field, and the letting out of the water.

A curious superstition prevails with regard to the insect, and is entirely believed in by the cultivators. The notion being that the surest way to get rid of the pest, is for a man or boy who has been born in the month of Bhadro, to walk over the field and stick a leaf of a date tree in some part of it, then to pinch off the heads of some of the insects and bury the headless bodies in the field. The superstition has so strong a hold on the minds of the cultivators that whenever the pest appears they invariably (and sometimes at great expense) seek out a Bhadro-born man or boy and get them to perform the ceremony.

The tree bark borer seems to have no local interest. The following we must quote :—

10. BAMBOO INSECT.

Mr. G. Anderson, of Munzerabad, Mysore, sends pieces of jungle wood attacked by an insect locally known as “Cootee.”* He writes :—

“This class destroys bamboos, watties (basket-reeds) and many jungle woods. The natives have a superstition that no jungle poles or bamboos should be cut when the moon is full, as they argue that the sap is then very abundant, and unless the bamboos are well soaked in a tank and subsequently preserved with plenty of smoke they will be rapidly destroyed by the *cootee* and other borers. The advice is excellent and should be invariably adopted, but it would be interesting to know what actual effect the moon has on the motion of the sap in growing trees. These insects also attack the pod, or capsule of cardamoms, and, I think, are propagated in the forest rubbish; but the fact that I have found the insect in the larval and perfect state inside the capsule, suggests the probability that the female punctures the outer skin, lays its eggs therein, and the grubs, having passed the pupal stage, emerge as perfect beetles by the small

* Indian Museum Notes, issued by the Trustees, Vol. I., No. I. Notes on Indian Insect Pests;

† Letter dated 7th January 1889.

‡ Indian Forester, Vol. I, p. 197 (1876);

§ This may possibly be a mistake.

round hole, leaving the cardamoms perfectly empty. 'Cootee,' also attacks horse and cow-gram (*Dolichos in-flosus* and *lablab*) and will utterly destroy solah pith hats, bread, baskets, mats, &c.*

The insects which Mr. Anderson sends belong to a species of Bostrychidæ Beetles (Apatides), which, however, it has not been possible to identify precisely in Calcutta; specimens have therefore been sent to Europe for comparison.* It may be observed that all the substances which Mr. Anderson mentions, are not likely to be attacked by the same species, though they may be attacked by species which are very nearly allied to each other. The idea which prevails with regard to the effect of the moon is a curious one, and would really seem to have some foundation of fact to rest upon, the writer having been told that it prevails generally, both in Behar and also in the North-West. About the only explanation that has been put forward is to the effect that the 'cootee,' like most other wood boring insects, prefers to lay its eggs in wood which has commenced to wither, and which consequently has no longer a healthy flow of sap to interfere with the insect in its burrow, though still full of nutritive juices on which the insect feeds. If this is the case, the time immediately after the bamboo has been cut down would be the most likely one for it to be attacked; and moonlight nights would give the insect a quiet time, with plenty of light, for finding the bamboos and ovipositing in them. This explanation, however, is little more than a guess and requires confirmation.

It seems to be the generally received idea that soaking bamboos, and also other timber, in water, for a considerable time, immediately after it has been felled, makes it less liable, than it otherwise would be to suffer from boring beetles of all kinds. It is supposed that not only does the water prevent the beetles laying their eggs during the time the wood is immersed in it, but that it also drowns the larvæ already at work, and dissolves much of the nutritive matter on which they would otherwise feed.

It is notorious that bamboos suffer very considerably from the attack of small boring Bostrychid (Apatid) beetles. The writer has found that sponging the bamboo over with kerosine, in sufficient quantity to penetrate into their burrows, destroys the insects effectively and prevents further damage. This treatment, however, is obviously only applicable in a limited number of cases.

The mango weevil (*Cryptorhynchus mangifera*) is represented as spreading in India. Next we have:—

12.—DERMESTES VULPINUS, Fabr.

Plate IV, fig. 2, a larva (dorsal view), b larva (side view), c pupa, d imago; all enlarged; fig. 2, e imago (nat. size).

Some specimens of *Dermestes vulpinus*, the leather beetle of America, have recently been sent to the Indian Museum by Mr. J. Oleghorn, of Rajshahye, who says that the larvæ attack eggs, worms, chrysalids and moths of the mulberry silkworm. During the rains cocoons having often to be reeled off, on account of damage done by this insect, within a fortnight of having been received, instead of being allowed to ripen as in the hot weather, The cocoons are thereby depreciated in value, sometimes to the extent of £12 per maund. Mr. Oleghorn has observed that the insects are most abundant during the rains, their numbers diminishing during the months between October and May, though causing loss of produce even during these months.

So long ago as 1839 Westwood, in his Modern Classification of Insects, wrote that *Dermestes vulpinus* occurred throughout Europe and America, and also in Java; that it had at one time done so much damage in skin warehouses in London that a reward of £20,000

* Specimens of this insect were submitted to Dr. Günther, who had kindly undertaken to have them examined. He has since reported on them as belonging to a species of *Stenoxylon* which is unnamed in the collections of the British Museum. He also reports on a second species that was obtained by Mr. R. D. Oldham, in Dehra Dun, from a tent pole, which it had completely destroyed, as belonging to a species of *Dinoderus*, not in the British Museum collection.

was offered for an available remedy, without, however, any being discovered, and that an entire cargo of cork had been destroyed by it, the insects also damaging the timbers of the ship.

We quote the following with reference to the revival and we trust the full success of cotton cultivation in Ceylon:—

THE BOLLWORM.—In the Museum collections is a specimen of the Noctues moth *Heliothis armigera*, ticketed as having done injury to the poppy crop in Patna in March 1879; there is also a half-eaten poppy-seed capsule apparently eaten by this worm, which is ticketed as having been damaged by an insect known as *kujra*; that is also injurious to the potatoe.

In March 1887 specimens of *Heliothis armigera* were received from Arrah, where the insect was said to be injurious to poppy. In 1887 some caterpillars doubtfully referred to this species, were received from Mr. J. Cameron, of Bangalore, who writes that they live chiefly on pulse crops, and especially on *Dolichos lablab*. A single caterpillar, also doubtfully referred to this species, was received in January 1888 from Mr. R. Rainey, of Kulna, who reported the insect as having been injurious to paddy. The Museum contains specimen of the moth which have been obtained from several localities in India, and the species has been recorded as occurring in Ceylon, Europe, Africa, America, Jamaica and New Zealand.

In America it is known as the "Bollworm," and has proved most destructive to cotton, Indian corn, leguminosæ, and many other plants. A most complete account of it was given by Dr. Riley in the fourth report of the United States Entomological Commission, p. 354 (1885). In the case of the American insect, Dr. Riley notices that the eggs are deposited all over the cotton plant, the larvæ pupating in the ground and generally hibernating in the pupa state, though generation after generation is produced until the approach of the cold weather. Dr. Riley recommends autumn ploughing for destroying the pupæ, in countries where there is frost; the destruction of the moths by poisoned sweets and lantern traps; the destruction of the early broods of larvæ, in the restricted areas where they first appear, by hand-picking, or better by *Pyrethrum*; also the encouragement of insectivorous birds and poultry.

THE AMSTERDAM CINCHONA AUCTIONS IN 1888.

[It is rather strange that the complete return for 1888 is only given in the *Chemist and Druggist* of 4th January 1890. It will be seen that the total of bark sold was equal to 4,977,410 lb. which averaging 4.12 per cent. of sulphate of quinine was quite equal, we suppose, to about 10 millions of Ceylon bark. Java most certainly, rather than Ceylon, may be said to rule the cinchona market in the future.—Ed.]

Our Amsterdam correspondent sends us the following statistics relating to the cinchona sales which took place in Amsterdam in 1888:—

Date of Auctions	Total quantity of bark		Of which were:—		Average percent- age of quinine sulphate	Average unit of the manufac- tured barks
	Kilos.	Succirubra barks	Ledger barks	Total weight in quinine sulphat Kilos.

PLANTING REPORT AND CROP ESTIMATES.

A planter who travels about a good deal sends in his estimate for the current season's Exports, too late to be incorporated in our average results, so we reprint it in full, together with a report on prospects:—

Tea.—I doubt its reaching the 40,000,000 lb. Coffee 90,000 to 100,000 cwt. Cinchona bark: a very big drop may be looked for—probably to 5,000,000 lb. Cocoa:—crops are not lasting so well as was expected: 16,000 cwt. at the outside. Cardamoms: 200,000 to 250,000 lb.; people are rushing in for cardamoms at a great pace and no doubt prices are encouraging.

I have no fear of Labour Supply running short, except it may be a sudden *rush* of leaf here and there; people will complain of it then! Rice—Chetties all crack it on *terrible!* I hope it does not go much higher.

Our N.-E. monsoon is full of vagaries! and one does not well know what to think, dry weather is succeeded by welcome rain which came down on 12th, and 13th; we expected more, but alas! this cold wind is driving it all away again; meanwhile the little we have had has made a tea jump again!

I went through the Dikoya and Maskeliya districts a short time back and was surprised and pleased to see the "Old King" looking so well, on the patches still reserved, and I have advised some friends to "pull out the tea"; and fig the old "chappie" up with matter that may do his heart good and put on another crop or two!

Parchment in one or two favoured stores knee deep, and the old pulper being rattled round right merrily by the waterwheel quite reminds me of "old time." May we live to see some more of it.

THE RICE CROP IN BURMA.

The report on the prospects of the crop on the 31st December is as follows:—"The area under rice cultivation in the ten chief rice-producing districts of Lower Burma is now estimated at 3,813,294 acres or 182,214 acres more than the area under cultivation in 1888, and 5,154 acres more than was estimated last month. It is reported that there is a 20-anna crop in two districts, an 18-anna crop in one district, a 17-anna crop in four districts, a 16-anna crop in two districts and a 15-anna crop in one district. It is estimated that there will be available for export 1,260,000 tons of cargo rice, including what will be required for Upper Burma."—*Government of India, Calcutta, Jan. 11th.*

GEMMING IN CEYLON THROUGH LIMITED COMPANIES.

A contemporary pretends not to understand how the present multiplied attention (through Syndicates and Companies) to the Ceylon Gemming Industry has arisen. He wilfully ignores or undervalues the influence of the press! We think that the persistent way in which during the past year, we have urged the claim of our gemfields to the attention of European capitalists, affords the explanation required. Ever since the formation of the Burma Rubies Company, we have preached from the text that if Burma deserves to have so much British capital (over £300,000) thrown into it for a new and, to a certain extent, speculative industry, much more ought the peaceful and readily accessible Colony of Ceylon, with its old established gem pits worked solely by the natives with primitive appliances for more than a thousand years. We think this argument is unanswerable, and as the result proves, it took effect on the minds of leading financiers in London and Paris, who, it is evident, are now

fully prepared to do justice to the development of local gemming resources. One expert who first had his attention drawn to the subject in this way, went straight to the Colonial Office, Downing Street, and asked for any works of reference to the Minerals and Precious Stones of Ceylon, and at once our compilation of "All About Gems, Pearls, &c. in Ceylon and Southern India" was produced, and perused with full satisfaction. We learn again that it required but a glance on the part of an expert at the native workings in Rakwana, to see how modern scientific appliances could be used with immense economy and of course far more complete results. Without at all wishing to make too much of the start made, we think we are safe in saying that for the first time in the history of the island, a full and satisfactory investigation with machinery and other scientific appliances is to be given to our gemmiferous country, and that not through one Syndicate or Company, but through several Associations owning or leasing or prospecting over a very considerable area of land. So much even now, from the information at our command, we regard as settled; and whatever be the result, we think such trial workings—which we trust and are hopeful may prove very successful—should be regarded with gratification in the interests of the Colony, while the fact of their being undertaken is undoubtedly due largely, if not mainly, to the information supplied and circulated from the *Ceylon Observer* press.

GEM FIELDS AND PROSPECTS.

(By a GOOD AUTHORITY.)

As regards big gems, the Morawak Korale is coming to the front very much this season. A catseye weighing $4\frac{1}{2}$ rupees has been recently found. This stone, I am informed, sold for R19,650. It will have to be cut into three pieces. A ruby weighing 2 $\frac{1}{2}$ rupees has also been quite recently found, and I am informed sold for R40,000. I have myself seen a ruby 23 carats (rough), and six other smaller ones, a sapphire weighing 156 carats, a catseye of 32 carats, and some ruby stars, for which the owner asked the modest sum of R25,000. By dividing this amount by 5 you arrive at their full value. A rough ruby changed hands for R2,500 last week. All Morawak Korale stones, a sapphire Rakwana R1,400, two catseyes (Rambukoya and Ratnapura stones) R2,000 and R3,000 in the trade. The latter, I believe, have since been sold to Mr. H. M. Stewart who left by the "Robilla." Mr. Stewart bought a lot of rough Burma rubies in Singapore, but I am informed they were not up to much, being full of silk and flaws. Burmah rubies beat Ceylon for color, but also for silk and flaws and want of fire.

New fields are being discovered every day for gemming. I had a stone offered me by a Sinhalese who is gemming in Maskeliya, near a Mr. Wright's estate he says. Beside this I have been stones from Dikoya. The great prospectors will no doubt open our eyes this year if they don't loosen our purse strings. Fahey will get Brown (brown), Brown will be feeling Baddeley (badly) and Baddeley will want to go to Galway (Galwey) or perhaps Galle way if things get too hot for him up in old tracts.

DOMESTIC FUEL HERE AND AT HOME.

The recent and prospective rises in the price of coal throughout Great Britain have caused very serious misgivings, not only on the part of manufacturers and others who are large users of the article but on that of the ordinary householder. The cost of fuel is a very large item in the

expenditure of a family at home, and the addition to this that is to be faced has caused the friend who has on several occasions given us the results of his experience as a guide to those of our island community who may contemplate settling in the old country, to send us remarks on this special branch of domestic outlay. What the cost of fuel here in Ceylon is, is, of course, well-known to every household, and we need not therefore touch at length upon this branch of our subject. It is, however, fully realized here how greatly the amount of this particular item varies in different localities. In some of them it is really a very serious item of domestic expenditure, apart from the large and increasing demands of tea and other factories. Some thirty years ago now, as we are informed, the expenditure of the Government Agent at Kandy on fuel was but little below—if at all below—the ten rupees weekly. It is true that the then incumbent of that office entertained very extensively, and all his arrangements for hospitality for the numerous guests he received were made on the most lavish scale. Still, when it is remembered that his salary was at that date but £1,500 per annum, the fact that one-thirtieth of it went for fuel alone is sufficient to prove that even here in Ceylon, in certain localities within it at least, the item of domestic fuel is no light one, for firewood is now far scarcer and dearer than it was a generation back.

But when we turn our attention to the colder climate of England, it will be seen how natural it is that the annual domestic coal bill is one which necessitates the exercise of a very careful economy in the use of fuel by those whose incomes reach but to a moderate standard. The consumption of an ordinary middle-class family, our friend tells us, as the result of his own experience and that of inquiry widely made, ranges from an average of one ton monthly to five tons monthly. In cases when there are very young children, both day and night nurseries must be kept at an equable temperature; and in the case of families where this has to be done the suavity or mildness of a winter makes a very considerable difference in the household expenditure. Perhaps, our friend considers, it will be well to accept a mean for families whose gross expenditure is between £500 and £600 per annum of 2 tons monthly throughout the year. The price of coal at present in London is twenty shillings per ton for kitchen coal and twenty-five shillings per ton for coal used for other purposes. These prices will seem moderate enough when it is recollected that a hundred years ago the price of coal in London ranged between £2 and £3 per ton. What the poorer classes must have had to suffer in those days, when wages were quite 100 per cent below their present standard, may well be realized from this fact. The amelioration of their condition as the result of the construction of railways and the employment of improved methods of "winning" coal—as it is termed—is certainly not among the least of the benefits to the wage-earning classes which the passage of a century has wrought.

Pursuing the theme of the communication by our friend, it may be set down that the expenditure of a moderate household in England for domestic fuel averages about £30 a year. Several economies may, however, be practised which tend somewhat to reduce this amount. Many people find it inconvenient to store two descriptions of coal, and, as a matter of fact, what is sold as kitchen coal is amply good enough for all general use, though of course the higher descriptions give a brighter fire and burn with less of

residuum, and are consequently less provocative of dirt, than the commoner kinds. In the mere matter of cost, however, a very considerable reduction may be effected in the coal bill by foregoing these two advantages. Then, again, in many frugal households coke is largely burned in combination with coal. This is a very efficient fuel for use in the "kitcheners" with which most English kitchens are now furnished. Indeed the strong draught which is possessed by such an apparatus causes coal, when employed by itself, to burn away with a rapidity alarming to economical housewives. The admixture of it with coke in such cases is therefore almost obligatory, and this is a material which is so cleanly to handle and store that it may be housed in almost any available corner or cupboard. Our friend, indeed, advises its partial use even in sitting-rooms, though he admits that in many cases of delicacy the fumes given out by it unfit it for extended employment for such purposes, and he counsels that it should never be used in nurseries or for the heating of sleeping rooms. Still he advises careful use of it by those to whom economy is necessary, and in the case of his own domestic experience he has found that by following out the use of kitchen coal for all purposes, and that of an admixture of coke, about five fires can be kept burning throughout the winter season—and the kitchen fire of course all the year round—for about £15 per annum. Such an outlay, our correspondent thinks, may be accepted by those of our readers who have in view a residence at home as a sufficiency for this branch of their estimated expenditure. But it is certain that, in view of the anticipated rise in miners' wages and other conditions likely to affect the cost of coal raising, this datum may certainly be expected to prove inadequate. It affords, however, a basis on present rates quoted, upon which a reliable estimate may always be formed.

ARTIFICIAL JEWELLERY.

The Parisian master is a critic of precious stones; he knows how to cut, how to mount, and, immediately afterwards, how to imitate them; he is an artist in enamel, mosaic, and gilding; he can amalgamate gold with silver, producing every kind of splendid illusion. Jewels, true or false, are in constant demand, and for the production of the latter variety a philosopher's stone of some sort must be found, which shall convert cheap substances into glories. The false French diamond, for which so enormous a desire has for years been exhibited at Paris, was, until lately, the very centre of this sparkling commerce. It is a bit of colourless paste, superimposed upon another, with a darting central radiance, both perfectly white, except for the prismatic aurora incessantly playing through them.

The ordinary materials employed in the fabrication of false precious stones are of a very commonplace character. A Parisian mechanic, engaged upon these manipulations, may be required to make a false diamond out of white sand; first, he washes it with hydrochloric acid, and then with simple water. Minium, calcined soda, borax, and oxide of arsenic are subsequently added, and a perfectly lucid combination results; but when the Parisian artisans come to the sapphire—the second in their estimation of all precious stones—they have to deal with its wonderful and varying colours, and the obstacle lies in the production of that lovely dark light burning in and bursting from its heart, for which the stone is famed, in all its hues—white (the rarest), pale blue, ruby tinted, vermilion, milk coloured, violet,

and green. The Jews of Amsterdam will charge you a hundred guineas for sapphire! but buy a little strass and oxide of cobalt and you can make one for yourself. Little need be said of the Parisian fabrication of chrysoberyls, chrysopals, and "floating light," which are really not jewels in the strict sense of the term. The last, known in the slang of the French market as aquaphonanes, are of an asparagus green, rather shell-shaped, with two refractions, and pretty enough when flashing under a galaxy of chandeliers. In imitating the ruby—always providing that mere red glass and the other pitiful ideas of toy arcades are out of the question—great difficulties have to be overcome. Properly speaking, there is only one ruby (known to the lapidaries as the spinel), of a tender red; the Oriental, Barbary, and Brazilian are generally sapphires, amethysts, or topazes. The colour of the true stone may best be described, perhaps, as a combination, exquisitely delicate, of rose and cherry; but some are wine-tinted, or of a violet hue, or tinged with yellow. It is astonishing how far a mixture of white lead and pulverised and calcined flints will go in competition with the jewel beds of India. So with emeralds; the same paste that is used for artificial diamonds is blended with a precipitate of oxide of copper, and the green gem sparkles brilliantly. The garnet requires paste dyed with the "purple of Cassius"; it is, however, exceedingly difficult to imitate its starlike ray. Oxide of cobalt and the Cassian purple will produce a beautiful semblance of the amethyst, though a better is obtained by a mingling of white sand, treated with hydrochloric acid, red lead, calcined potash, calcined borax, and the purple. Thousands of these mock gems are annually sold, at considerable prices; and thousands of them are worn by those who would have the world believe in heirloom jewels.

The manufacture of false pearls, which had its origin in the French capital, and thence spread to Italy, is exceedingly curious. As its foundation are used the scales of the blay, a small flat fish, with a green back and a white belly, the latter being of a very silvery appearance, and easily detached. The scales are scraped into bowls of water, dried in a horse hair sieve, melted, and converted into "essence of the East," to which is added a little gelatine, and this mixture is spread, with the utmost care, over delicate globes of glass. When cool, these are pierced and filled with white wax to give them the necessary solidity and weight. Occasionally, real opals, powdered, are used for the most costly kinds. The trinkets imported as "Venetian pearls" are glass, and their production presents no difficulty.

Infinite care is bestowed upon the mounting of spurious gems by the French artificer. He has to consider how his sham settings—they must be sham, since he must sell them cheap—are likely to suffer from exposure to the atmosphere or from the action of heat, water and acids; and he resorts to copper, lead, platinum, iron, steel, gold, silver and their amalgams accordingly. The history of their manipulation by his or several sets of hands, the softening, the purification, the moulding, the washing, the hammering, the melting, the colouring or bleaching, the chiseling, and so forth would about occupy an entire technical dictionary. There are instruments for stamping, instruments for welding, instruments for soldering. One workman chamfers, another files, another stands at the laminating machine; the fourth bends over the delicate enameller's knife, sharp as a diamond's edge, and nearly as hard; a fifth subjects the completed work to a microscopic examination. This industrial economy

is peculiarly interesting, the diversity of aptitude, of course, encouraging the division of labour.

Reverting to the French meretricious jeweller's other arts—those of coating common with precious materials, and enamelling, few have any idea of the extent to which these tricks in manufacture are carried. The ingenious and cheap French enamel, white or coloured, made up into rings, collarets, and bracelets, brings a great profit to the workmen, and is really attractive. But it requires time and study to obtain a mastery over this art. There is the fixing of the translucent glass upon the metallic surface, the painting of the vitreous plane, the choice of tints, the subtle application of heat, the consideration of chemical action exercised by one oxide upon another, and the due admixture of materials. Then, the engraving of enamels is a task requiring all possible exactness and tenderness of touch. Gilding, or as the Parisians style it, "gold" colouring, calls into requisition methods the most various, the oil, the hot, the cold, the bronze, the copper, the steel, and the ether; but the magic of silvering is scarcely less intricate, especially when the surfacing is to be totally false, or what is termed "argenterie des charlatans." As for coating copper with gold which is quite different from gilding, this belongs altogether to a higher artistry, applicable also to lead, and even to iron.

The manufacture of steel trinkets by the French is of old date, and the finish and polish of the fancies produced for the Palais Royal by the artificers of the riotous Faubourg St. Antoine have never been excelled, even by the ambitious mechanics of Austria, who are Dutch in their perseverance and Italian in their taste. But, after all, these artists aim mostly at the imitation of jewels and gold.

A number of workmen in Paris have, for many years, been dependent upon the mock jewellery industry, and thrived by it. It is not by any means a degrading business, simply because the deception is, in fact, no deception. It is avowed in the marketplace; the objects are sold as shams; no one of common sense or knowledge could take them to be anything else; but they bring, or have usually brought, to the artisans of Paris an enormous annual income.

NATIVE AGRICULTURE IN INDIA.

(From the *Indian Agriculturist*, Dec. 28th.)

Dr. Voelcker, who left Calcutta for Cawnpore on the 20th instant on tour, has come to India for twelve months under special engagement with the Secretary of State for the purpose of suggesting improvements in Indian agriculture through scientific means. As far as his observations have extended, Dr. Voelcker has been struck by the evidences of careful cultivation which he has seen in the country through which he has travelled. Nor has he failed to recognise the difficulties in the way introducing agricultural machinery and the free employment of manures in this country. It is believed that Dr. Voelcker has been especially charged by the Secretary of State to deal thoroughly with the question how the wheat trade between India and England can be improved and developed. Dr. Voelcker's researches are also, we think, to be extended to the conditions under which linseed is now exported to England, more especially with a view of preventing the adulteration of the seed and securing a completely satisfactory oilcake for use by British farmers.

According to the Director of Agriculture in Bombay, Mr. Dhimbhai Kirparam, the ryots do not need to be familiarised with the rotation or interculture of crops, nor do they appreciate the benefits of high farming; but they want such help as will enable them to utilise the results of science, and adopt such practical methods in agriculture as well-tested experiments have

incontestably shown to lead to better results. They have, for example, to be taught the advantages accruing from the interchange between different parts of the country of the best selected seeds for grains, fruit, and vegetables; and they have to be taught what mixtures they have recourse to in cultivation to protect themselves in seasons of drought and famine, and to save themselves from the caprices of the season or the continuance of bad seasons. The fullest information might also be given regarding the diseases of crops and the remedies therefor, as well as regarding the animals and parasites to whose ravages crops are subject. Dr. Voelcker will no doubt utilise his time in India by drawing up a compendium of instructions for the improvement of Indian agriculture, suitable more or less to all parts of the country.

An ensilage experiment at Poona seems to have proved completely successful. A *jowari* crop, 68,000 lb. in weight, was cut flowering at the end of September, 1888, and placed in the silo pit the following day. The filling process took fifteen days, the silo was filled a foot above the brim, and the top layer was covered with a four inch layer of weeds. When the temperature rose to 120 degrees F., the top was plastered over with a layer of clay two inches thick, and the whole was weighed down by a layer of *moorum* a foot thick. After five months the silo was opened, when the silage was found to have sunk two feet below the brim. It was, however, almost as fresh as when put in, and was greedily eaten by the farm cattle as green food throughout the hot season.

NORTH-BORNEO: PROGRESS DURING 1889.

POLITICAL.—A BRITISH PROTECTORATE over British North-Borneo became an established fact during last year, the Protectorate also being extended to Sarawak and Labuan. In addition to this the Court at the request of H. M.'s Government have agreed to administer the Colony of Labuan, and as this number of the *Herald* is published, the ceremony of installing His Excellency C. V. Creagh as Governor of that Colony is proceeding. For the first time in the annals of the State a Durbar has been held at Sandakan. It took place on May 28th last at Government House, when chiefs from all parts of the territory met His Excellency Governor Creagh. The event has made a fixed and lasting impression and will greatly help to extend the influence of the Government over the more remote tribes of the interior, and greatly improve the relations between the people and their rulers.

TERRITORY.—By the successful conclusion of the little war with Pangeran Shabbander in February last, the independent state of Padas Damit has been incorporated in the Company's Territory, and now forms an integral part of Province Dent. The war was brought to a successful termination by the capture of the Fort Galila, and the submission of Pangeran Shabbander, who had also to accede to the oft repeated demand of our Government that Patek should be surrendered to undergo his trial at Brunei for the murder of one of our subjects, who was also in the employ of the Government. This gives us a large additional area of capital Sago land, and there are parts of the district where it is stated tobacco can be planted. Independently again of this addition to our agricultural lands, a long standing nuisance has been swept away. We are rid once and for all of the constantly outcropping question on the subject of boundaries, and the country in the neighbourhood has now every chance of peace. In old days Padas Damit was as far as we were concerned a sort of Alsatia where murderers, robbers, and criminals took refuge to avoid the just punishment of crime committed in the Company's Territories. It was always also a matter of suspicion that conspiracies against our Government were fomented there, while arms, ammunition and other contraband of war were smuggled into the district from Labuan and other places. Now we have changed all that. We believe also that in addition to this we shall shortly be able to announce the acquisition by purchase

of the Inanam, Membakut, and other rivers the native chiefs of which are willing to come under the Company's rule. Government being desirous of avoiding any further troubles with the Brunei Chiefs have offered liberal terms for all these rivers within the Company's boundaries, and the Government proposals are being considered by the Sultan of Brunei with whom the settlement of this long vexed question now rests.

PLANTING.—As in the year 1888 so in the past year tobacco has made greater strides. Two new estates have been opened in the Kinabatangan, a new estate has opened on the Labuk another on the Tungud a tributary of the Labuk. The Sugut is also progressing and all the estates in Darvel Bay are looking well. The Segaliud estates in Sandakan Bay are also very highly spoken of. Experts who have been visiting the various estates during the year are loud in praise of the samples inspected by them on the Darvel Bay plantations, and on Mr. Vander Hoeven's estate on the Labuk river. Ranow in Marudu Bay as usual is still to the front as also the other estates in Marudu Bay. A crop from Banguey island sold at an all round price of 2/5 per lb. in the Home Market, the purchaser reselling two days later for 2s 11½d per pound. On the strength of this the German Company open 100 new fields this year. Some tobaccos have realised up to 5s 6d per pound. The Sungei Koyah estate in the Kinabatangan has produced tobacco of an excellent quality which is most highly spoken of. On this river there are five estates at work and two more to open shortly. Tobacco land has been raised to \$6 per acre and applications coming in. The *Deli Cowant*, the organ of the Sumatra planters, stated the other day in a recent issue, on the authority of an expert (a disappointed one evidently,) who had visited this country, that British North Borneo did "not contain an acre of land suitable for tobacco planting." This is curious coming as it did simultaneously with the news from home of the famous quality of our tobacco and the prices fetched in the Home markets. Our planters already see their way well on to success, and are not likely to be discouraged by anything they may read in the paper in question. Mr. Christian's coffee estate at Kudat realized the very satisfactory price of 60s in the cherry and 80s clean. This estate is to be formed into a company, the capital increased, and works carried on on a much larger scale.

TIMBER.—Next to Tobacco, Timber naturally takes the second place in our list of products. This industry has greatly increased during the year. First and foremost the China Borneo Company have erected and nearly completed an extensive Saw Mill about half a mile from the B. B. T. and P. Co.'s mill. Communication by telephone is laid on from the Mill to the Company's Office on the Praya, and also at the residence of the Managing Director of the Co. Mr. E. E. Abrahamson. A full description of the engines, appliances &c., of this mill was given in our last number. Part of the machinery is now at work and we hear treating some 24 logs daily. The China Borneo Co. have this year sent away sixteen ships containing 5,000 tons of Bilian and other timbers to the Hongkong and China Markets. The B. B. T. and P. Co. sent away the full rigged American ship O. C. "Chapman" with a cargo of 700 tons during November. We anticipate a very large output of Timber from the China Borneo Company's Mill during this year.

IMMIGRATION.—Large numbers of coolies, Chinese and others have arrived in the Colony during the past year, principally Immigrants from Singapore and China, and several coolies have arrived from Java. These coolies have naturally been mainly absorbed by the Tobacco Companies in Sandakan, and Marudu and Darvel Bays. Sandakan and Kinabatangan Labuk and Sugut rivers have taken some 4,000 alone, an equal number being divided between Darvel Bay and Marudu Bay. Several free labourers have arrived in both Sandakan and Kudat and have started as Carpenters, Agriculturists, Shopkeepers &c. The price of Labour however has not been much reduced and work being always to be had there is room for more to come. In

addition to these some hundreds of natives from the Spanish and Dutch territories are settled in various places under the Company's protection.

SIGNIFICANCE OF GEMS AND COLOUR.

The following remarks by Mr. William Cooper, in an American contemporary, will be read with interest. Certainly no portion of external nature is disregarded by science, but neither is anything which it contains outside the domain of poetry. And as poetry is more ancient than science, as well as in all ages the most kindly of its foster parents, the very commonest things were often ennobled by it long before they became objects of particular study, as, for instance, precious metals and gems. Language, *per se*, is the flowering forth in speech of the intellect and the emotions, while poetry with her ready wand of metaphor touches the most ordinary of objects and converts them into the most sublime. In nothing is this more exemplified than in the goldsmith's craft and precious stones.

The poetical employment of the precious metals is as old, at all events, as literature itself. It has been stated that the allusions, in the Old Testament to gold number fully 250. The majority, no doubt, are of purely literal intent, as when we read of the golden crowns worn by monarchs. Goodness, purity, unflinching faithfulness of heart, with concurrent gladness and peace are in all cases intended by gold, when thus employed as a metaphor. A drop of molten gold is one of the most ravishing objects the eye can rest upon. Qualities and properties possessed by gold are in no other metal, and indicate a truly noble, representative character. Shakespeare introduces the word in many a familiar line, as "golden sleep" and the "golden cadence of poetry," &c.

Silver signifies, in ancient lore, that which we commonly designate as a clear and quick-sighted intellect a shining and elegant mind, purity and truth, *i. e.*, "A word fitly spoken is like apples of gold in baskets of silver." Love has been likened to

The silvery link, the silken cord
Which heart to heart, and mind to mind,
In body and in soul can find.

But to gems, or precious stones, the poet's art has similarly supplied many a beautiful image, alike in secular as well as sacred literature. The diamond, the ruby, the sapphire, the emerald, the jacinth, the topaz, the turquoise, represent in their several ways, all different, though harmonious, emotions and qualities of the human heart. So do the admired stones we call spars and crystals, marble and alabaster, amethyst, opal and agate, jasper, jet and lapis lazuli; with not far off those other lovely gifts of nature, outcomes now of plant and animal life—amber and ivory, coral and pearls. What beauty can equal the ravishing eloquence of the beauty of a chaste pearl! The mere word "pearl," conveys the idea of all that's lovely, refined and holy.

Colour is one of the grandest factors of the language of nature. Excepting in the tender pictures where the gray hairs of old age find a fitting place, we have nothing in the way of colour that is neutral or diluted, from the ancients, down to the present time.

Red is representative of dignity and inexpressible worth, chastity and lofty propriety of conduct. Thus: "Who shall find a virtuous woman? for her price is far above rubies."

Blue is identified with the early royal robes and the priesthood, representing constancy, loyalty, patriotism and fidelity.

Green is the colour of spring, hence it was that in the olden time the emerald was reputed to be a certain cure for the bite of venomous snakes; thus it is today that an emerald ring is considered the most appropriate gift to the betrothed.

Yellow and white are the colours respectively of gold and silver. White comprehends also the quality of innocence, a meaning quite consistent with that which links silver to intellectual worth.

Combine red with blue; mingle, as it were the ruby and the sapphire, and we then have purple.

the colour representing, in all ages, that which is consummately grand and illustrious—nature's united masculine and feminine.

What dignity resides in black, though custom associates this colour with ideas of bereavement and sorrow. While looking at it from the inferior or negative side, it is no doubt quite natural to do so. Black is soon discovered to have its more cheerful metaphor as well as dismal one. All the finest and richest shades of black are suffused more or less with lustrous purple, as shown so beautifully in the glorious plumage of the raven or rook; or again, when in combination with white it shows up in contrast with that colour's brilliancy and purity, so that jet is not merely a badge or adjunct of mourning, but is as cheerful in its significance as even the emerald itself.

All of these points go to prove what a delightful study that of precious stones is, and how we raise our trade and ennoble our own minds by cultivating a full appreciation in others of nature's rare and beautiful gems.—*Home paper.*

RAT PEST AMONG COCONUTS IN THE LACCADIVES.

The depredations committed by the swarms of rats among the coconut plantations in the Laccadives being the cause of great loss of revenue, the islanders appealed to the Collector of Malabar to supply them with arsenic to destroy the vermin. But as an immense quantity of the poison would be wanted, and great and unceasing vigilance required to prevent the remedy being a cause of danger to the community, the proposal has not met with approval. Mr. Winterbotham suggests the introduction of the large corbie crow which would prove an effectual rat catcher; but the Government has asked Mr. Winterbotham to first of all consult Dr. Bidie, Mr. Thurston, and other naturalists on the most effective way of destroying the rats; and it has also suggested the use of dry powdered plaster of Paris sprinkled on boiled rice. This when consumed induces intense thirst, on quenching which the plaster hardens and kills the animals within a short period. The islanders get up periodical rat hunts, in spite of which the animals increase at a prodigious rate.—*Madras Mail*, Jan. 17th.

RAW COTTON is, as everyone knows, one of the most important staples of the Indian export trade, and cotton manufacture one of the most important of Indian industries; but these facts have perhaps never before received such strong emphasis or adequate illustration as in a manual of cotton statistics which has just been published by a Bombay merchant. Who "A. F. B." is we can only surmise; but he must be a man of infinite patience and assiduity: there is scarcely a detail missing concerning the cotton trade or industry, the production of the fibre, the number of the mills, or the peculiarities of consumption, on which statistics are available. Perhaps the point of most general interest is the testimony which the figures of consumption bear to the extraordinary development of cotton manufacture in the country. We know this from the enormous increase in exports of twist, especially to the East; but it is brought home even more forcibly when we find that, whereas in 1886-87 the consumption of raw cotton in Indian Mills was only 60,000 bales, last year it was close on 889,000 bales, an increase in two and twenty years of 1,381 per cent. This may not be the most striking instance of rapid industrial development on record, but considering the political and economic conditions of the country in which it took place, it is certainly the most remarkable.—*Pioneer*, Jan. 11th.

[We should think so; and further it seems probable that the time is at hand when India will cease to export raw cotton, all she can produce being used in her own mills.—*Ed.*]

NATIVE ENTERPRISE IN TEA.—We learn that several native gentlemen are engaging in tea-planting on a considerable scale in the Bentota district: one of them, Mr. Clovis de Silva, a well-known Moratuwa renter, is opening about 200 acres of forest land, and doing his work on a thoroughly liberal scale. Other clearings of 40 to 100 acres are reported.

THE DIAMOND INDUSTRY OF AMSTERDAM.—The industry at present is in a sad plight, owing, it is said, to the dearth of the rough stones. More than 7,000 diamond cutters are believed to be idle at this moment. So much, at least, was stated without contradiction in a mass meeting of over one thousand workless cutters, held the other day at Amsterdam. It is now proposed to start a co-operative diamond cutting factory, for which a capital of half a million guilders is required. If the money cannot be found in Amsterdam, the promoters propose to transport 5,000 or 6,000 workers to London, and negotiations have already been opened to that effect with the Rothschilds, who would provide the necessary funds for the emigration scheme and the London establishment. Nothing is as yet settled.—*Industries.*

THE CHEMICAL TRADE OF GERMANY.—The American Consul at Mannheim, in a recent report, states that Germany exports to all parts of the world all kinds of drugs and chemicals in a finished state. Last year about 233 million marks worth of raw material was exported, and 236 millions worth of manufactured chemicals was exported from Germany. This branch of trade forms 7 per cent. of the total trade of the Empire. The raw materials imported included medicinal drugs, resins, pitches, and tanning stuffs, while the exports were composed of bases, acids, salts, ether, oils, medicines, perfumeries, colours, &c. The Consul says that the Germans are labouring with ceaseless energy to get the command of this profitable and important branch of commerce. Time, money, and energy are expended in ever-repeated efforts to beat others and secure new discoveries. In Mannheim and the adjacent towns "a large number of skilful chemists are constantly employed producing and experimenting. The gold mines of an El Dorado or the silver ores of Colorado are not richer in yielding wealth than the laboratories of these establishments. Their alembics yield more wealth than the necromancers of the middle ages dreamed of getting from theirs."—*London Times.*

ASSAM.—Assam, under the rule of Mr. Fitzpatrick, enjoyed a year of more than average prosperity in spite of a very heavy rainfall, and the comparative failure of the cold-season crops. The tea industry was severely tried by the weather, but although in some parts the outturn was prejudicially affected, the total production amounted to upwards of 72½ million pounds, or nearly 4½ millions more than in the previous year. At the close of 1883 there were 863 tea-gardens in the province, a favourable sign of the times being the amalgamation of six gardens with others, with a view to economy and convenience of working. The largest outturn was that of the district of Sivasgar (16,127,240 lb.), followed by Cachar (15,477,096 lb.), Lakhimpur (14,481,587 lb.), and Sylhet (13,575,338 lb.) All districts except Cachar and the Khasi Hills showed an increase as compared with the preceding year, but the falling off in Cachar alone was considerable (1,079,202 lb.) and is attributed to the weather and the prevalence of blight. The average outturn per acre for the province was 386 lb. against 384 lb. in the preceding year, and, as in previous year, the gardens in the Lakhimpur district were most productive with an average of 522 lb. per acre in 1883, against 487 lb. in 1887. Comparing the two valleys, the average yield per acre in the Surma Valley was 3.9 lb. against 3.79 lb. in the preceding year, while in the Brahmaputra Valley it was 415 lb. against 388 lb. in the preceding year.—*Englishman.*

TEA IN BADULLA DISTRICT.—Writes a planter on the 20th instant:—"Old Gonakellie has now nearly 800 acres in cultivation and the tea is grand." Well done! And yet there are croakers who say the estimated tonnage of traffic will not be available for the railway: why each acre of tea gives much more traffic up and down than a similar area of coffee, and besides cinchona is bound to keep up in Uva.

THE CEYLON TEA PLANTATIONS COMPANY which is announced as once more earning 15 per cent on its capital in the island and whose splendid Mariawatte property has done so well again last year, is evidently full of confidence in the future of our tea enterprise. We judge this from the large way in which they have been buying and adding to their tea investments out here of late. From Sir Wm. Gregory they have bought the Dimbula estate of Tangakellie with 323 acres of tea. Some time ago they took over the Alton property in Maskeliya with 410 acres; and the other day another estate purchase was reported by a contemporary which we cannot refer to at the moment. But today we learn on, we believe, good authority that Mr. Herbert Anderson of Dimbula has arranged to sell to the Company his valuable and extensive Dimbula estates of Holyrood—nearly 500 acres under cultivation—and Waverley of 157 acres. The Ceylon Tea Plantations Company, it is evident, therefore, is in a fair way to own a greater acreage under tea than any other proprietor or Company connected with Ceylon. We wish them continued success in their investments.

NYASSALAND.—The Rev. Horace Waller, the companion of Livingstone, has come out with a timely volume on Nyassaland, and from a review in the *London Times* we learn how great is the progress made not only by Mission bodies, but in planting and commercial settlements. One firm Messrs. Buchanan Brothers has taken up some hundreds of square miles of splendid land suitable for coffee, tea, cinchona &c., and they have begun planting coffee and cinchona in good earnest—200 acres of the former having been put out already with large nurseries and clearings of land for extension. And all this is in the territory which, for the first time in history, was lately invaded and claimed by the Portuguese! No wonder though Lord Salisbury was firm remembering how from Livingstone's day onwards, the settlement has been uniformly British.—From the notice in the *London Times*, we quote as follows:—

He does justice to all the branches of the Church that are carrying on the work of civilization in the Shiré highlands and in the neighbourhood of the lake; as also to the enterprise of the Lakes Company. He gives especial prominence to the work of the Buchanan Brothers, who, on the slopes of Mount Zomba, have coffee, sugar and cinchona plantations, with the necessary machinery for the manipulation of the produce. Their estates at the present time extend to over 50,000 acres of the very best and healthiest land in Central Africa. The titles to these lands were granted by native chiefs; copies were lodged with Consul Hawes on the spot, and also with our own Foreign Office. Sawmills and sugarmills have been erected, and tropical plants are on their trial from various parts of India and other countries. Last August no fewer than 27,000 additional pits for coffee-trees were dug on the Mudi estate, bringing the acreage up to close on 100, while at Mlungusi and Mount Zomba another garden also of 100 acres is in full bearing. Moreover, very large tracts of land in the neighbourhood of Blantyre have recently been purchased by gentlemen in England and Scotland, who for the most part have examined the country for themselves. This is just one fact among many presented by Mr. Waller as constituting the British title-deeds to Nyassaland.

THE YATIYANTOTA TEA COMPANY, LTD.

Report of the Directors for presentation to the Annual Ordinary General Meeting of the shareholders to be held on Friday, 7th Feb. 1890, at noon.

Directors: Charles Young, Esq., A. Thomson, Esq., W. D. Gibbon, Esq., W. H. G. Duncan, Esq.

The Directors have pleasure in submitting to the Shareholders the Accounts of the Company for the past year. The crop secured in the year was 153,107 lb. of made Tea, being 13,107 lb. in excess of the estimated quantity, and the cost of laying it down in Colombo amounted to R36,955.25. In addition to the produce of the estate, 5,632 lb. of Tea were made from purchased leaf at a cost of R2,534.40; whilst the average net price realized for the total out-put of 158,739 lb. was 48 cents per lb.

After making the usual provision for depreciation of Buildings and Machinery the net profit for the year (including a small balance from 1888 account) amounts to R29,475.18, equal to nearly 33 per cent on the paid-up Capital. An interim Dividend of 8 per cent was paid in August last, absorbing R7,200, and of the balance of profit the Directors propose to apply R15,300 in paying a further Dividend of 17 per cent, to place R6,500 to credit of an "EXTENSION FUND" and to carry forward to next year's account the remaining R475.18.

During the year the Company has acquired from Government at upset price 143 acres of land adjoining Polatagama estate, making the total acreage owned by the Company 910 acres, which with Buildings and Machinery stand in the books at a cost of R100,262.54. The Directors have decided on extending the cultivation of Tea on Polatagama, a course which they have no doubt the Shareholders will approve, and arrangements have been made to plant up 54 acres early this year. The estimated cost, to the end of 1890, of this extension is R4,800.

The crop in 1890 from 404 acres is estimated as 170,000 lb. Tea against an estimated outlay on the estate of R43,000.

In terms of the articles of association Mr. C. Young retires by rotation from the office of Director but being eligible, offers himself for re-election.

TANNIN IN CEYLON AND INDIAN TEAS.

The extract under this heading which we append, will be read with interest by all connected with the growth and manufacture of tea, and also by many who use the fragrant leaf and desire to ascertain the time for infusion which will give a strong but not a harsh liquor. The period may be taken at 5 to 7 minutes, with perfectly boiling water. In most cases, it will be seen from the article quoted, one-third of the tannin contained in the leaves was extracted in five minutes, while close on 60 per cent was yielded in 15 minutes. The con-

clusions cannot be disputed that tannin is the source of strength in tea; that it is a natural constituent of the leaf and cannot be suppressed by modes of cultivation or manufacture. It does not follow, however, that cultivation and especially manufacture may not develop this constituent in varying degrees, and so with theine. We should like to see analyses of teas from natural soil of an ordinary character and the produce of the same land when treated with nitrogenous and phosphatic manures. We know that, as the result of liberal manuring on an estate in Chittagong, not only was the yield of leaf increased, but appreciably better prices obtained for the produce sent to market. The remarks with which Mr. Cochran has favoured us will receive respectful attention from our readers. He notices that, so far as his experience shows, there is small difference in the proportion of tannin in tea grown at medium and high elevations in Ceylon. But certainly the results of Mr. Hooper's analyses do not disprove the popular idea that the proportion of tannin in tea is in general ratio dependent on altitude,—being more abundant in low-grown tea and diminishing with height above sea-level. Eliminating the curiously exceptional case of the Travancore tea, which can probably be explained by local circumstances, the order in which the teas are classed for average tannin has marked reference to elevation, thus:—

Assam (generally under 1,000 feet) ..	18.6
Ceylon (generally sea level to 6,000 feet) ..	17.9
Coorg (about 3,500 to 4,500 feet) ..	16.13
Nilgiris (5,000 to 7,000 feet) ..	15.3
Darjeeling (same as Nilgiris) ..	15.0

If Coorg did not intervene, the comparison would be as between 17.9 for Ceylon teas, many of which are low grown, to 15 for the Nilgiris and Darjeeling teas, which are grown at high altitudes. Granted that modes of manufacture may not affect the proportion of tannin inherent in tea (10 to 25 per cent: average about 16),* Mr. Cochran's experiments show that the next most important constituent, theine, is certainly affected. An analysis of tea leaves in the green state made by this gentleman showed a very considerably larger proportion of theine than was yielded by roasted tea. We append Mr. Cochran's remarks:—

"According to your extract from Mr. David Hooper's paper the average amount of tannin in Ceylon teas is a high one. However, these figures appear to be the result of only 13 analyses, and I am inclined to think that a more extended series of analyses would show a considerably lower average. My own experience is still very limited. I can only give data from 12 samples of Ceylon teas, six of these from an estate at medium elevation, and six from an estate at a high elevation. At medium elevation the lowest result was 9.8 per cent of tannin (gallo-tannic acid), and the highest 12.36, the average 11.36 per cent. At the high elevation the lowest was 9.98 per cent, and the highest 11.23, average 10.41. Judging, however, from some experiments I made with green tea leaves, I do not doubt that there may be lowcountry teas in Ceylon which would yield up to 19 or 20 per cent of tannin. The lowest amount of tannin I have found was in a sample of tea from the Nilgiris, which only yielded 8.94 per cent. The moisture, however, in this sample was high, viz., 8.80. If calculated to tea with 5 per cent of moisture the amount would be raised to 9.30. These figures represent what could be obtained from the tea leaves, after boiling them with water for one hour. The precipitant used was not acetate of lead, but acetate of copper, which I found by repeated experiments on the same tea to yield very closely concordant results. I might mention that in a series of analyses of

Indian green tea leaves undertaken by O. Kellner, to ascertain the effect of season on the composition of tea, he found that between May 15th and Nov. 30th the average amount of tannin in the particular tea experimented with was 10.6 per cent, calculated into the dry matter of the leaves. The lowest amount was on the 15th May, viz. 8.53 per cent; and the highest on Nov. 30th, viz. 12.16 per cent. Mr. Kellner exhausted the leaves not with water but with alcohol. Dr. Battenhall gives, as the result of the analyses of Indian teas by American chemists, the following figures for tannin: 13.04 to 18.868 per cent, average 15.323. The samples analysed represent 2,414 packages, and the process used for the estimation was in many, probably in most, cases the acetate of copper process. I am of opinion that the popular view that tannin decreases with elevation is true for Ceylon; but it may be found, as the few analyses I have made would indicate, that while the difference in the tannin between low-grown tea and tea grown at a medium elevation is marked, the difference in respect of tannin between medium and high-grown tea is relatively small. I do not think that the different modes of preparation will appreciably affect the amount of tannin in teas. It requires a temperature of 482 F. to decompose gallo-tannic acid."—M. C.

TANNIN IN INDIAN AND CEYLON TEAS.

(From the *Chemist and Druggist*, Jan. 4th.)

Mr. David Hooper communicates to the *Chemical News* a paper on this subject which is based on analyses of 65 specimens, 29 of them from the Nilgiris (including 10 green teas), 6 from Travancore, 3 from Coorg, 13 from Ceylon, 6 from Assam, and 8 from Darjeeling. There has hitherto existed most erroneous notions regarding the amounts of tannin in tea. Thus Mulder's figures for black tea are 12.88, and green tea 17.80 per cent. Dragendorff found in teas of Russian commerce 9.42 to 12.70 per cent.; Jank obtained a maximum of 9.14, and a minimum of 6.92 per cent. in eighteen samples; Wigner, analysing some astringent teas, reported as much as 27.7 to 42.3 per cent., Hassell gives as the average 15.24 in black, and 18.69 per cent. in green teas; Clark found from 5 to 19 per cent.; and Geisler, an American chemist, obtained 14.87 as the average percentage of tannin in a large number of packages of Indian teas imported into New York.

Mr. Hooper's analyses show that the percentage in black teas ranges from 10 to 21 per cent., his lowest, 10.14, being that of a Nilgiris Congou, and the highest 21.22 per cent., afforded by a Travancore broken Pekoe. The following figures are calculated from Mr. Hooper's table, which is too long to reproduce, and show the totals of tannin extracted:—

Samples.	Highest.	Lowest.	Average.
Travancore (6) ...	21.22	17.37	19.63
Assam (6) ...	20.3	16.18	18.6
Ceylon (13) ...	20.87	15.00	17.9
Coorg (3) ...	16.93	15.15	16.13
Nilgiris (19) ...	18.55	10.14	15.3
Darjeeling (8) ...	17.74	13.61	15.0

The specimens of green tea were taken from two different estates on the Nilgiris, and showed an average of 19.1 per cent of tannin, the highest being 24.37 and the lowest 11.52 per cent., the latter being a coarse leaf. The effect of the figures is to show that the finest teas are those which contain the most tannin, and there is a gradual declension of this principle as we approach the Souchongs and Congous. The elevation does not appear to affect the amount of tannin, as has been supposed. The Dodabetta estate, the highest in the list, shows a smaller percentage of tannin in the leaf than all the rest, but does not very much differ from the samples from Aratapara, some 4,400 feet below; and in this respect there is very little to learn from the altitudes of the Ceylon teas. The highest tannin content occurs in Travancore tea of the Sea-field estate, a tea of great fragrance, and considered to rank very high-class in the home market, and the Glenorchy Broken Pekoe of Ceylon, although containing 19 per cent of tannin, is one of the best-priced teas

* Mr. John Hughes' analysis of tea from a Nuwara Eliya garden gave "soluble tannin" so low as 6.37 per cent.—Ed.

of the island. Other determinations, referred to above, show that the kind of shrub cultivated in India contains more or less tannin according to its original habitat. The amounts of tannin were obtained by perfectly exhausting the leaves, precipitating the filtered decoction with acetate of lead, weighing the dried lead precipitate, and calculating as gallo-tannic acid.

The infusion of the family teapot extracts more or less tannin, according to the sample used and the time allowed for the leaves to soak in the boiling water. The brokers' test of five minutes takes out one-fifth of the extract, with a corresponding amount of tannin. The teapot infusion of ten minutes removes about one-third, fifteen minutes one-half, and twenty minutes two-thirds. The following experiments were made to show the amount extracted by infusing 1 per cent. of tea in boiling water for five and fifteen minutes:—

— Tannin	Extracted in five minutes		Extracted in fifteen minutes	
	Per cent.	Per cent.	Per cent.	Per cent.
A ...	11.08	3.04	27.4	—
B ...	12.10	4.40	36.2	6.88
C ...	12.32	4.28	34.7	—
D ...	13.25	—	7.88	59.5
E ...	13.55	4.60	33.9	—
F ...	23.50	6.26	26.6	9.52
				40.0

The tannin is, undoubtedly, the source of the "strength" of the tea, and the higher the tannin the richer the infusion, and the more of body will the sample possess. Tannin is likewise a natural constituent of the tea, and is not amenable to suppression by higher cultivation or by the ordinary processes of manufacture.

CEYLON TEA IN GLASGOW.

Mr. Andrew Polson, wellknown as a respected Ceylon planter, seems to have been among the most energetic of established home agents of Ceylon tea. He is now Director of the "Indian Tea Bazaars Co. Ltd," Glasgow, with a capital of £25,000, the object of which is thus indicated in the prospectus:—

"This Company has been formed for the purpose of acquiring and extending the business at present, carried on in Glasgow, Dundee, Greenock, Leith, Hull, and other places, under the name of "The Indian Tea Bazaars."

"The business consists of the sale, wholesale and retail of Indian and Ceylon Teas, Coffee, Cocoa, &c., for household consumption and otherwise, and the sale of these articles as refreshments in Tea and Luncheon Rooms specially fitted up for the purpose. This business the company proposes to develop and extend over the whole of Great Britain as opportunity offers." Writing to a friend in Ceylon, Mr. Polson says:—"We state without fear of contradiction that the Indian Tea Bazaars Co., Ltd., put out more Ceylon Tea than any company or firm in Scotland. It was a disappointment to me and to the manager that we could not have had the name altered from Indian Tea Bazaars Co. to a more distinctive Ceylon one."

From a very picturesquely illustrated pamphlet issued by the "Indian Tea Bazaars" some years ago, we see that they have a long list of agencies and new ones have lately been added in the South of Scotland and North of England. The pamphlet itself is taken up with India and its tea; but a specimen of the canisters now issued with tea is before us, gorgeously lackered and coloured, with a picture of a Tamil girl resting from plucking on the top; and on the sides, representations of Mutval boutiques and palms, talipot tree and elephant, Kandy Lake and Colombo Clock-tower and street. These tins are used for pure Ceylon teas only. We wish Mr. Polson and his Company continued success through a largely extending business.

THE NEW MINING ORDINANCE,

Among the half-dozen drafts of new Ordinances, this is perhaps the most important and most generally interesting. It is called:—

An Ordinance relating to Mines of Gold, Silver, and Precious Stones in Lands other than Crown property.

But this Ordinance may be cited for all purposes as "The Mines Regulation Ordinance, 1890."

From the rest, we quote the important clauses and sideheads:—

In this Ordinance—"Land" means every description of land not being the property of the Crown, and includes the bed of every river and stream adjacent to or flowing through such land.

"Mine" means every mine which from and after the date of the coming into force of this Ordinance shall be opened for the purpose of searching for or obtaining gold, silver, gems, or precious stones, and includes all shafts, levels, planes, works, machinery, tramways, and sidings both below and above ground, which may be sunk, driven, erected, or constructed in and adjacent to any such mine.

"Shaft" includes pit. "To open a mine" means and includes the sinking of any shaft or the driving of any level or inclined plane, or any act whatsoever whereby the soil or earth or any rock, stone, or quartz in or under any land is disturbed, removed, carted, carried, washed, sifted, or otherwise dealt with for the purpose of searching for or obtaining gold, silver, gems, or precious stones therefrom.

"Person" includes any association or body of persons whether incorporated or not.

From and after the coming into operation of this Ordinance, it shall not be lawful for any person to open any mine without having previously obtained a license as hereinafter provided.

The government agent may issue a license to open a mine in any land within his province, reserving for the use and benefit of Her Majesty and her successors such share, not exceeding one-tenth, of the gross value of the gold, silver, gems, or precious stones which may be obtained from such mine as the Governor in Executive Council may from time to time determine, or such fixed annual rent in lieu thereof as may have been agreed upon between such government agent and the licensee, and such license shall be substantially in the form set out in the schedule hereto.

(1) Before any license is issued, the person applying for the same shall furnish the government agent with a declaration in writing containing—

(a) the name and boundaries of the land in which the mine is to be opened;

(b) the nature of the right of the applicant to open the mine on such land; and

(c) the name or names and residence or residences of himself and of the person or persons under whose management or superintendence the mine is intended to be opened and worked.

(2) If the party making such declaration ceases to have an interest in the mine, or if any person or persons other than those named in the declaration shall be entrusted with the management or superintendence of the mine, the licensee shall make a further declaration thereof to the government agent.

Every such declaration shall be signed by the party making the same, or by his duly authorised agent, and shall be filed of record in the office of the government agent.

License may be refused or revoked. Appeal to the Governor in Executive Council.

Production of license, which is not transferable.

The government agent shall from time to time make, and when made may alter, amend, or cancel rules for—

(a) securing the share reserved to Her Majesty and her successors of the gross value of the gold, silver, gems, or precious stones obtained from any mine, or the rent in lieu of such share;

(b) inspecting and examining into the state and condition, and ensuring the due ventilation, of any mine or any part thereof;

(c) regulating all matters and things connected with, or relating to the safety of the persons employed in or about any mine and

(d) every other purpose necessary for carrying out the several provisions of this Ordinance.

Any person who shall open, work, or use, or cause or suffer to be opened, worked, or used any mine in breach of, or in any way contrary to, the provisions of this Ordinance or of any rules made under section 8, or otherwise than in strict accordance with the license in that behalf granted under this Ordinance, or after such license shall have been revoked, shall be guilty of an offence and be liable on a first conviction to a fine not exceeding fifty rupees, or to rigorous imprisonment not exceeding three months, or both, and on every subsequent conviction to a fine not exceeding one hundred rupees, or to rigorous imprisonment not exceeding six months, or both.

When any person is convicted of mining without a license, or contrary to the conditions thereof, all the gold, silver, gems, or precious stones or mining implements which at the time of the commission of the offence were found on the person or in the possession of such offender shall be liable, by order of the convicting magistrate, to confiscation, and such confiscation may be in addition to any other punishment prescribed for such offence.

In any prosecution instituted under this Ordinance against any person for having opened, worked, or used any mine without a license, the burden of proof that he holds a license shall lie on the party accused, and until the contrary shall be proved he shall be deemed to have no license.

THE PRUNING OF TEA.

Mr. Wood of Langa Tea Estate, Sylhet, recently made some inquiries regarding the effects of pruning on the tap root of the tea plant. As some of the points raised have an important bearing on the question of treatment of young tea, especially in all gardens and dry districts, Mr. Wood's queries were sent to Dr. King, and his replies, with the questions, are given in the Proceedings of the Agri-Horticultural Society of India, and are here reproduced:—

1st.—Does the tap root of a tea plant extend downwards in proportion to the height of bush?

2nd.—At what proportion? Ans. (1). As a rule, yes; (2). Local conditions may, however, modify the proportionate growth of roots to size of bush.

3rd.—Does pruning arrest the downward growth of the tap root entirely, partially or does it encourage its downward growth? Ans. Partially arrests; certainly does not encourage.

4th.—Does pruning, when the sap is up, arrest the downward growth of the tap root entirely, partially, or *vice versa*? Ans. Pruning when the sap is up weakens the bush, and anything which does that probably diminishes the growth of the roots.

5th.—Does pruning when the sap is dormant arrest the downward growth of the tap root entirely, or not at all? Ans. Pruning, when the sap is not in full flow upwards, probably affects the root very little, if at all.

6th.—Is the sap in a tea bush (*i. e.*, evergreen) ever entirely dormant? Ans. Not entirely. Evaporation from the leaves never quite ceases, and sap must be continually supplied from the soil to keep them alive.

7th.—Supposing the very top, or succulent part, of the main stem of a two-year-old seedling be plucked—does this in any way stop the downward growth of the tap root? Ans. I cannot answer: experiment would have to be made.—*Indian Planter's Gazette*, Jan. 14th..

NATAL TEA COMPANY.

The second annual general meeting of the shareholders connected with the Natal Tea Company was held in the office of Messrs. Steel, Murray & Co. (secretaries) on Thursday afternoon. There were present:—Messrs. T. S. Flack (chairman), T. H. Drury, W. R. P. Murray, E. Snell, Geo. Goodricke, W. Peck, W. Bowhill, J. S. Wylie, and Davidson (manager).

The directors submitted their annual report, of which the following are the principal paragraphs:—

The lease of the company's tea plantation terminated at 1st Nov. 1889. Under the lease agreement the company were entitled to purchase a large tract of land at a fixed price per acre. A portion of the ground leased having been found useless for tea cultivation has been given up, but your directors are pleased to state that they have on behalf of the company secured about 250 acres, including the ground upon which the tea beds of the company are situated, with a new portion of ground adjoining, which runs further into the country. The price and payment have been made on favourable terms for the company.

The manager of the company reports that he is well pleased with the appearance of the tea plants as sprung in the beds, that they are strong and healthy, and bearing well in proportion to their size, and he is proceeding to transplant as speedily as possible on the new ground acquired by the company. The tea beds contain plants sufficient to plant out the whole of the company's ground. There have been transplanted this season 9,850 plants, and there are about 1,434,500 plants in the tea beds.

The tea grown and made by the company is of good quality and flavour, and finds a ready sale at good prices. As the season is only beginning for tea picking, the quantity obtained so far has been small, but warrants your directors in hoping the company will prove a success if the plants grow steadily and in "flush" and tea bearing.

The company have during the year imported, and have now working at their plantation, (1) a tea rolling machine, and (2) a tea drying machine. The Manager reports that he is very well satisfied with these machines, and is now in full working order to secure this season's crop, the picking of which lasts till March next.

Mr. Swinburne, the manager of the company, had in the beginning of the year to leave Natal on account of ill-health, and is not to return. Mr. Davidson, for some time previously in the company's employment as assistant manager, has been appointed to succeed him.

The directors hope, under his energetic management, the prospects of the company may rapidly improve.

The statement of accounts showed a balance of £250 out of the capital of £2867. Tea seed had cost £424, labour £508, the European establishment £223, formation £83. The sale of tea, &c., had realised £141.

The Chairman in moving the adoption of the report and statement of accounts, said he was pleased to preside over the largest meeting yet held of the company, which for a young venture, was in a fairly satisfactory position. He trusted the shareholders would visit the estate at Isipingo, and by their suggestions assist the directors in their labours.

After a short discussion, during which the Chairman said the company might require some slight assistance pending returns coming in,

Mr. Snell seconded the motion as above proposed, and the reports were unanimously adopted.

On the motion of Mr. Goodricke, seconded by Mr. Snell, the appointment of Mr. J. W. Leuchars on the Board of Directors was confirmed, and Mr. W. R. P. Murray was re-elected director.

Mr. J. Sinclair was re-appointed auditor at the usual remuneration.

It was also resolved to alter clause 49 of the Articles of Association so that the directors might be empowered to hold the annual meeting in April instead of December, it being pointed out that the picking season ended in March; which would enable the Board to finance better for the company's year.

Votes of thanks to the Chairman and directors for their valuable services during the past year brought the meeting to a close.—*Natal Mercury*.

SERICULTURE AT SAIDAPET.

The result of the Honorable Mr. J. H. Garstin's visit to the Saidapet Farm on the 15th instant, reported in our issue of that date, which was made with a

view to the selection of a suitable spot for experiments in sericulture, has been that he has chosen a plot of land about one acre in extent for the purpose. The site at Meyur, in the Chingleput District, selected by Mr. Rego, was considered inconveniently distant from Madras, and therefore abandoned. About R2,000 has been estimated by Mr. Rego as the cost of the experiments, nearly one-half of which will have to be spent in wire netting, with which the selected land is to be enclosed. Casuarinas and plants of quick growth, upon which the tassa worm usually feeds, are to be at once planted, and these plantations are to be protected on the top by netting of Bengal twine to prevent inroads from the natural enemies of the worm. The trees will be sufficiently grown to afford food for the young worms by July next, which is the month for the bursting of the cocoons, the pairing of moths, and the laying of eggs. The nursery will be guarded by three men, while Mr. Rego will occasionally visit the spot, and afford all the information he can to those who require the same in regard to the rearing of the tassa worm and sericulture in general. Should the trees not be sufficiently grown by July, food for the worms will be procured from elsewhere.—*Madras Mail*, Jan. 22nd.

A FREE BREAKFAST TABLE.

TO THE EDITOR OF THE "TIMES."

Sir,—Will you allow me, as one who has always advocated a reduction or abolition of the import duty on the wholesome and palatable teas of India and Ceylon, to direct public attention to the disastrous results that would inevitably ensue from any ill-advised attempt to bolster up the trade in the doctored and deleterious products of the heathen Chinese by any general abolition of the tea duties? It will be admitted by everyone who is acquainted with the tea trade that any such indiscriminate abolition will act simply as a heavy bounty, paid by the British taxpayers, to the Chinese producers of those low-priced teas which, even under present conditions, do so much to injure the good name of tea as a wholesome article of food. For the abolition all round of a duty of 6d a pound means a reduction of something like 33 per cent on the average cost of production of Indian and Ceylon teas; but it is a reduction of at least 100 per cent on that of the low-class China teas.

The course of trade of late years has shown incontrovertibly that the British consumer, if left to himself, prefers the pure and wholesome growths of his own fellow-countrymen in India and Ceylon to those of China. Moreover, for every pound of tea that we purchase from India and Ceylon, we are able to sell to those countries a proportionate amount of our cotton and other manufactured goods, far greater relatively than our sales to China on the same inducement. An immense amount of British capital is now invested in the tea-gardens of Assam, Darjeeling, and Ceylon, and is now, solely on the merits of the tea produced, beginning to yield a fair return, which return, if the trade be not checked by fiscal changes, is daily becoming larger. But this trade, I think, would be greatly injured, and am sure that the cause of temperance would be greatly discredited, if the cry of "a free breakfast table," seductive as it sounds, were to induce us to give protection to the cheap and nasty growths of China.

Of course, it will be obvious that the better and more wholesome teas of China—of which, equally, of course, there are many—will suffer equally with the teas of India and Ceylon from any such ill-judged measure.—Yours faithfully,

ROPER LETHBRIDGE.

Carlton Club, Jan. 8th.
—*London Times*, Jan. 11th.

[Sir Roper Lethbridge goes a little too far—at any rate 2d to 3d off the duty would benefit the distribution of Ceylon teas in the packet business very considerably.—ED.]

SIR LEPEL GRIFFIN AND THE RUBY MINES OF BURMA.

We (*The Times*) are informed that Sir Lepel Griffin, at the urgent request of the board and principal shareholders of the Burma Ruby Mines Company,

has consented to visit and inspect the property of the company in Upper Burma, and that with this object he will, accompanied by Lady Griffin, leave England by this week's Indian mail.

The work that Sir Lepel Griffin will have to perform may be thus described:—He will have to inspect the property, to supervise the organisation of the staff who are already engaged and at work, to arrange any matters which may be under discussion with the Government, to look to the working of the rules to be put down smuggling under the special regulations, and generally to see what has to be done to make the concern a profitable one as speedily as possible. It must not be supposed from this statement of what has to be done that nothing has yet been accomplished towards realising the expectations formed of the ruby mines district, or that the affair remains still in embryo. The most important piece of work done is the completion of the road from the Irrawaddy to Mogok, a distance of 60 miles. This road is now in perfect working order, as may be inferred from the fact that a lady contemplates travelling by it to visit a remote part of our Burmese territory. Moreover, heavy machinery has been conveyed along it to the mines. It is also important to note that a great quantity of machinery—cranes, steam pumps, and other implements whose use has been proved by mining experience in America, Australia, and Africa—has already reached the spot, is on its way to the mines, or has been ordered in England. A considerable staff under the direction of Mr. Lockhart as chief superintending engineer, and Mr. Atlay as company's agent, has been organised, with its headquarters at Kyatpyen, while Major Adamson, the Deputy Commissioner at Mogok, has, on behalf of the Government, actively co-operated in all the efforts to improve communications, and to put an end to the dacoities which still occur fitfully and on a small scale. The co-operation of the Burma administration has been assured, and is essential for the successful arrangement of all matters with the native miners who hold licences. Rules for the grant of licences were drawn up on Nov. 1st last, and these provide, among other things, that licences shall only be given to *bona fide* miners who have worked since the British occupation, that a fee of eight rupees a month for each workman shall be paid, that a licence shall be for only six months and not transferable, and that all fees on stones found go to the company, which, moreover, possesses the first claim on all stones dug up, and of these a careful register is to be kept, at the miner's risk of forfeiting his licence for not doing so.

These rules, excellent and comprehensive as they seem to be, may be found on further trial to require some modification, as it will be not the least important part of Sir Lepel Griffin's task to closely supervise them, so that while regard is paid to the interests of the native miners every means will be employed to insure for the company its legitimate advantages, and for the Government the increased rent to which the company's success will entitle it.

THE CORK PRODUCE OF SPAIN.

This industry flourishes in spite of the obstacles interposed in foreign markets. Thanks to the recent introduction of machinery for making cork, Gerona can compete successfully even with the cork industry of the United States, in spite of the *ad valorem* duty of twenty-five per cent. During the last few years, hundreds of machines for making corks have been introduced into the province, and have given work to numerous families in the rural districts, and the movement is likely to increase. The authorities and the proprietors of the cork groves seem to be

apathetic towards the ravages of the voracious worm which has wrought immense damage, and even threatens the extinction of the Spanish cork tree. But this year the pest has notably diminished on account of the attacks of a greenish beetle, armed with a kind of needle, and of another insect which enters the nest and devours the eggs during incubation.—*Electrical Trades Journal.*

THE TEA DUTY—A FREE BREAKFAST TABLE AND SIR ROPER LETHBRIDGE AND THE FUTURE OF CEYLON TEAS—THE PLANTING INDUSTRIES OF CEYLON BEFORE THE SOCIETY OF ARTS.

A subject which we observe has already received some amount of discussion by the Ceylon press has been brought into somewhat prominent notice among your colonists now at home by a letter addressed by Sir Roper Lethbridge to the *Times* which appeared in an issue of that journal early in the present week. The appearance of this letter has naturally led up to the passing of many remarks upon its topic by Ceylon men, and we find the views taken with reference to it by such authorities to be extremely divergent, some—though not many—fully agreeing with Sir Roper Lethbridge's opinions, but by far the larger majority dissenting from them. After carefully weighing what has been said on both sides, it seems to myself that, taken in two senses, there is much to be said for both lines of argument followed.

One gentleman—on whose judgment in such a matter we should be disposed to place great reliance—remarked to me:—"Unless pains have been taken to examine all the conditions attendant on the sale of tea generally—not that of Ceylon alone—among the poorer classes of our population, it seems to me to be scarcely possible for anyone to correctly estimate what the effect would be of any reduction of the present duty on tea. Now I have made it my business to closely inquire into the circumstances under which tea is sold among the people of Limehouse, Whitechapel and other similar districts of London, as well as in the small country shops in some of our remoter provinces. It should be remembered that it is the inhabitants of such localities—those in which our working classes mainly reside—who are the consumers of the bulk of all the tea imported. It is the 'millions' who are the customers of the tea trade, and it is their procedure, and not that of the 'thousand' who consume the more expensive teas, which must control the consideration of this difficult question. My experience is the great mass of tea is sold throughout the country at 1s 6d the pound. Out of this the retailer takes customarily a clear fourpence, while the dealer from whom he purchases takes fivepence, out of which he defrays all charges of packing, carriage, &c. To that preliminary 9d has to be added the universal duty of 6d; and we see, therefore, that, deducting this 1s 3d from the 1s 8d, the retail price, there remains but 5d available for the purchase of the tea in the Mincing Lane market. Probably, I should say, the general purchasing price does not exceed 4d, or perhaps 4½d at the outside. I know personally that in many cases the intermediate dealer is not content with the 5d mentioned above, and therefore feel sure that the purchasing price must be as low as 4d, though we will assume an average of 4½d. It is evident therefore from such a fact that at the present time very little of Ceylon tea can reach the 'millions' referred to. Such purchases must necessarily be confined to the lowest grades of China, and, possibly, to some of the coarser teas of India and Japan. It seems to me consequently certain that, were the duty taken off, it would

not have the effect—as Sir Roper Lethbridge assumes that it would have—of unfairly handicapping the average teas of India and Ceylon. Directly you apply the case to teas sold at 2s and upwards, a higher taste, that of the more refined palate, comes in, and the question of price does not assume the same prominent position. I do not therefore think that the removal, or reduction, of duty would in such cases operate one way or the other, and it is on these grounds that I deem Sir Roper's view to be a mistaken one."

In reply, it was remarked by me that my friend's argument might be held to cut both ways. It appeared to me that he was fully correct in his assumption as regards the higher priced teas, as with those it would manifestly be a question of taste and not one of price. But as regards the consumption of the poorer classes, were the duty taken off the percentage of disproportion between the rates at which common China teas could be vended and those at which the lowest grades of Ceylon teas could be sold would be more strongly marked than it is at present—that disproportion would appeal at once, and most strongly, to the poorer consumers, and must result in their showing even a stronger preference than they at present show for the cheap China teas. Put into figures, it seemed to me that the latter, sold at 1s 2d,—i. e. the 1s 8d less the duty,—would appear far more attractive than Ceylon tea sold at say 1s 5d;—the relative saving of 3d on the pound at those rates would appear greater—and would be greater—than the same saving on teas when the relative rates are, as now, 1s 8d and 1s 11d.

My friend admitted this, and ended by agreeing with my argument that the matter has to be considered in two lights; but said he hoped that in time the superior economy of Ceylon tea, on account of its greater strength, would redress the irregularity of price in the minds even of the poorer classes of consumers. But from what is known to me of the habits of thought of such people, being aware as I am that they rarely look beyond the price of purchase, it seemed to be very doubtful if they would ever realize in what direction true economy is to be found. My narration of these two views will inform you pretty fully as to the course of discussion here on this subject: my conclusion from all said to me relative to it being that the removal of duty, or of any part of it, might, and probably would, increase the consumption of "tasty" teas—that is those over 2s of retail price,—but not that of the bulk of your own lower grade teas.

But we are glad to think that this topic is shortly to receive a full public discussion, the result to which will probably be a clearer light upon what is certainly a somewhat intricate subject. It will be gladly heard by you, as affording assurance that the exhibit and vending of your teas at the Paris Exhibition have not been without effect, that Mr. Truman Wood and Mr. Cunliffe-Owen, having had their interest strongly excited at what then came under their notice, have requested Mr. Shand to read a paper dealing with Ceylon planting industries before the members of the Society of Arts, or, to give that Society its full title, the "Society for the Encouragement of Arts, Manufactures, and Commerce." On Tuesday next, in compliance with this invitation, Mr. Shand will address the members on "The Tea, Coffee, and Cocoa Industries of Ceylon." Calling this week on Mr. Shand in the hope that I might obtain an advance copy of his proposed paper, I found that gentleman just completing his sheets preparatory to sending them off to the printer, so

that a copy cannot be sent to you by this mail. If possible, I shall be present when it is read, but fear it will be impracticable for me to do this. Anyway, you shall have a copy of the paper and such information as may be obtainable respecting the following discussion to be expected, by the next mail. It is said that Mr. Shand proposes to illustrate his remarks by a carefully prepared table showing the relative course of the tea and alcoholic trades for some years past, and we hear that that table will be remarkable as indicating how steadily the upward course of the former trade has followed the downward course of the latter one.—*London Cor.*

COMMERCIAL OIL OF CINNAMON.

Mr. Frank E. Ballard, manager to Messrs. A. Moore & Co., of Smyrna, sends us the following interesting notes on the commercial tests for cinnamon oil:—

While living in Ceylon it was often my duty to examine and report upon various samples of the cinnamon oil of commerce, and to write certificates as to its specific gravity, it being the custom for Colombo merchants to send a sample of the article to a chemist for examination before accepting a consignment from the native producer, or giving an advance upon it pending its transmission to and sale in a European market.

This special work was quite new to me, so I began reading up the subject as far as possible, and at the outset found some little difficulty, by reason of the variations in specific gravity given by the various authors I consulted, no two of them being alike. Books failing me, I began questioning the buyers I met as to the means they adopted.

A gentleman told me he tested his samples by allowing single drops of the oil to fall into a glass beaker of water, and judged by the relative rapidity or slowness with which they reached the bottom as to their freedom from adulteration, the deduction being, that the lighter the oil the slower it travelled, and *vice versa*. Rather a risky and unsatisfactory operation, anyhow! Another buyer staked his money on his taste, and defined a good oil as one which tasted very sweet in the mouth, and left no hot, peppery after-flavour. This test, I afterwards found, had a certain amount of value. The specific gravities given in the books I consulted varied between 1.026 and 1.035, which leaves a very wide margin of doubt and uncertainty when applied to such a product as cinnamon oil.

I next tried to get a guaranteed specimen of pure quill oil as a standard. This was unobtainable, no merchant being able to state from what part of the plant any oil he had been distilling. It would not have done to depend upon a native specimen, so I was under the necessity of distilling it myself. This was done, and by careful collection I got $\frac{1}{2}$ oz. of oil from 12½ lb. of bark, all quill.

But such an oil! beautiful to see, delicious to smell, and as different from the native product as creosote is different from crystal carboic acid. It was of a bright pale golden colour, sweet taste, rapidly diffused, and leaving no bitterness on the tongue. Its sp. gr. was 1.019.

Now, whence came such abnormal sp. gr. as 1.026 and 1.035. I shall be able to show. On inquiry from distillers I found that they can produce, practically, as many grades of oil as they please at specific gravities between 1.019 and 1.045. The finest and lightest oil is the product of quill bark alone and will not vary in sp. gr. more than between 1.019 and 1.021. A second quality is produced from chips, root bark, broken quill, and the cinnamon *débris* of the factory generally. The sp. gr. of this oil will vary between 1.025 and 1.032. A third oil is distilled from the leaves alone, and is very different in its characters from the other varieties. It is light brown in colour, and sweetish, but it leaves an acrid burning taste on the tongue, and its odour is rough and when smelled after a fine quill oil, it is decidedly unpleasant. Its sp. gr. varies, but, as a rule, will be from 1.040 to 1.045.

With these data it is easy to understand the errors in description of specific gravities given by various writers on materia medica and pharmaceutical chemistry. They have never had a pure sample of oil for examination, but simply the common market variety, which is never—so far as I could learn from native distillers—prepared from quill bark alone, but is, as a rule, a mixture of the varieties named, in varying proportions. It would not pay them to send home a first-class oil, for the highest prices paid seldom pass 1s. 10d. per oz., and frequently an ordinary oil has been left unsold at 6d. or 8d. Consequently they send the bark to Europe, and make their oil from the refuse, and hence the sp. gr. is given in the United States Pharmacopœia as 1.040, and in Muter as 1.035; while MM. Salet, Girard, and Pabst, in the *Agenda du Chimiste*, give 1.033, and Hager 1.005 to 1.030. The British Pharmacopœia gives the *coup de grâce*, and tells us with the most charming naïveté that "it sinks in water." What a lucid definition!—*Chemist and Druggist.*

ROOT PRUNING.

We can do little to improve our climate—though much has already been done in that direction by thorough drainage and by deeper and better cultivation. The latter, in fact, may be called an extension to the utmost possible limits of surface drainage. And in so far as it perfects and completes surface drainage, it improves the climate; for every drop of water that passes through the earth instead of being lifted off it by evaporation, renders the earth and surface atmosphere warmer and drier in consequence.

But root pruning deals directly with the plant, or tree—not indirectly upon it through its environment, like superior culture and its surroundings. The main results of root pruning are the limitation of the supplies of food, and the improvement of its quality, and both processes tend to augment and sustain fertility. It may be—is, in fact, difficult to explain the whys and the wherefores of the operations that lead to such desirable results; but the facts themselves have been demonstrated over and over again; and some of the more potent causes of them may be formulated thus:—Granted a limited amount of heat, light, air, elaborating or manufacturing forces, and an unlimited quantity of food or raw material, the producer becomes handicapped or swamped by the excessive supplies of the latter. He loses, as it were, his legitimate power over the products produced. Experience also proves that excessive supplies of plant-food are mostly expended in wood-making. This is Nature's mode, unaided by art, of restoring the balance between supply and expenditure. The evils of an excess of plant-food may be modified if not cured by extending the area of their expenditure. As the plant grows larger, the pressure on over-fed vessels—congested elaborating organs—becomes less, and finally ceases. It may matter less to the plant than many suppose, whether the evils of an excess of food be cured through a mere extension of growth or augmented fertility. From the fact, that Nature left wholly to herself mostly takes the former course, we may infer that, on the whole, it is the best for the health and longevity of the plant. Both these plans, however, tend to rectify and adjust the balance between supply and demand, the acquisition and expenditure of force or food from without. Growth and fertility are both compensatory remedies for excessive supply.

Root pruning, on the contrary, is an instrument, and, as many too readily assume, an unnatural remedy for the same disproportion between force and functions. But really it is not at all unnatural, for what are our barren, hard subsoil—our shallow, poor tilths—our gravelly deposits, the prevalence of loose stones, and our solid strata of rocks, but so many natural instruments of root pruning, and a few of Nature's many means of cutting off perforce excessive supplies of food from the roots of our fruit trees and other plants? As what is most unnatural, is the planting of these on deep, rich soft tilths filled or mulched to repletion

with stimulating manures, and with every obstacle or check to root extension carefully removed, and then to profess to marvel greatly that Nature returns us for such food-gorging conditions great crops of wood, chiefly—or only.

Had fruit growers learned more, and to better purpose, the great lessons that Nature teaches, in almost any natural soil, even the artificial practice of root-pruning might never have been needed. For the natural checks to growth caused by scarcity of plant-food are intended to check growth and establish and maintain a high state of fertility.

Forgetting these lessons, the cultivator who has over-manured, and so over-fed his trees, with the one hand, has been compelled to prevent their consuming it to excess by pruning off a large portion of their roots with his knife in the other. But whether practised by Nature or art, the object aimed at in all root-pruning alike, is the enhancement of fertility by reducing excess in the food supplies. In the manipulation of the roots, either by Nature or art, for this purpose, we gain secondary advantages of equal, or even more importance than the primary one. These have been briefly referred to as improving the quality of food supplies. Without going into minute details, no one conversant with the more obvious and immediate effect of root-pruning will deny that it metamorphoses pipe-like roots into masses of fibres. Further, all practical fruit growers agree that in these fibrous roots the basis of fertility is laid, and the habit of continuous fertility perpetuated.

But not only does root pruning change the character, but the situation of the roots; generally it raises them nearer to the surface, exposes them to more heat, and brings them into contact with sweeter—that is, better and more immediately available food.

That much may be done through raising roots to more genial plains or fields of labour, is abundantly proved by the mere act of root lifting, where little or no, or as little as possible, of root pruning has accompanied the process. Barren trees have thus been made fruitful, cankered stunted trees become clean, and grown into robust health by thus forcing the roots to gather their food closer to the surface. By these and other methods, the root pruning, readily and necessarily, limits the supplies of food and improves its quality, and by both processes they succeed in establishing and perpetuating fertility. Much of success or failure, however, in these great culture and productive achievements, depends on the times, modes, and extent of rooting and pruning, and hence a second article may profitably be devoted to practical instructions on these important matters.—D. T. F.

[The practical results of root-pruning are obvious. The benefits of the process when judiciously performed are also obvious. But while in our present state of nescience we should hesitate to supply any other explanation of the causes of the good result than that furnished by our correspondent, we are by no means satisfied that he is correct. The increased production of fibrous roots resulting from root-pruning, so far from limiting the supplies of food must surely increase them, though it may regulate and diffuse the current of absorbed liquids. Again, the use of the word fertility in this connection is misleading. The growth of what we call the fruit is not necessarily an evidence of fertility, but only an extension of the vegetative growth by which leaves and shoots are formed. Real fertility consists in the development and ripening of the seed and of the embryo plant within it, which is another matter.—Ed.]—*Gardeners' Chronicle*.

DISEASES OF PLANTS.

By H. MARSHALL WARD, M.A., F.R.S., F.L.S. Romance of Science Series. Published by the Society for Promoting Christian Knowledge. London, 1889.

The student of botany fifty years ago devoted his energies almost exclusively to the collection of specimens; to him the formation of a "Hortus siccus" was the great object to be attained; while "life history" was as unfamiliar a term as "biology." During the latter half of the present century a complete change has come over the botanical world. The younger

botanists now turn their attention more and more to the study of the phenomena of life, which their predecessors so much neglected. Perhaps the advent of the Potato disease in 1845 had as much as anything to do with the popularisation, so to speak, of the study of plant diseases. The past generation of botanists troubled themselves very little as to how a plant lived, still less how it died. In this country we are yet far behind our continental brethren in the study both of biology and vegetable pathology. This has arisen from a variety of causes, such as the want of proper laboratories for botanical work, the lack of students willing and able to take up such investigations, but to a very large extent it has been owing to an absence of books treating of these subjects in our own language.

Foremost amongst the workers in this field of study stands the author of the book before us, and we heartily congratulate him upon the excellent little manual of *Plant Diseases* he has just published. Mr. Marshall Ward has produced a very readable and a very instructive book, treating of several of the more common and typical plant diseases, in such a manner that anyone who wishes to do so can understand all the main points connected with their production, their development, and the best available means of combating them.

Although one might think otherwise from its title, only those diseases of plants caused by fungi are treated of. The twelve chapters of which it consists are all of them worthy of careful perusal. They include the damping-off of seedlings caused by *Pythium De Baryanum*, Finger and Toe (*Plasmidiophora brassicæ*), the Potato disease, smut, bladderplums, the Lily disease, ergot, the Hop disease, and the rust of Wheat. Each of these subjects is treated of thoroughly and clearly from a biological stand-point. In the chapter on the Potato disease, a subject which has for so many years been the battle-ground of investigators, and which is consequently a very thorny subject, the author has succeeded in keeping clear of partisanship, and has given a lucid and exact account of the disease. In spite of all the work that has been done, there are yet many points connected with the life-history of *Phytophthora infestans* that would repay investigation; for instance, the duration of the vitality of the conidia under various degrees of dryness. The duration, too, of the vitality of the mycelium, both in the stems and in the tubers, is more taken for granted than demonstrated. We think the author has dismissed somewhat too summarily the possibility of checking the ravages of the disease upon the foliage by external remedies, such, for example, as the copper-salts, of which French mycologists speak so highly.

The title of Chapter XI, "The Rust of Wheat," is not happily chosen, as in this country the rust stage of the ordinary Wheat mildew, of which the chapter treats, is not by any means so prominent a phase as botanists would have us believe.

The Lily disease is, of course, treated by a master hand, and for the rest of the book we can find nothing but praise.—*Gardeners' Chronicle*.

TEA CULTURE IN NATAL progresses but slowly to judge by the report on page 564 of the proceedings at a recent meeting of the Natal Tea Company. In South Africa as in Russia, it will soon be found that it is more costly to grow tea than to import the pure article from Ceylon.

MICA.—I hear that the mica trade for electrical engineering purposes is just now very brisk. One of the London houses, Messrs. Wiggins & Son, at present executing a large number of orders for electric companies in England and on the Continent. —Our American contemporary, *Modern Light and Heat*, states that a patent has recently been granted to the Gould & Watson Company, of Boston, for the use of flake mica in electrical conduits. The system briefly consists of a box tube or electrical conduit, into which the wires are drawn, the conduit itself being filled and packed with flake mica.—*Electrical Trades Journal*.

THE NEW GEMMING ORDINANCE.

We call attention to a letter (page 576) which strongly condemns the new draft Ordinance and the Government for bringing forward such a measure at this time of all others. The occasion is felt to be most inopportune and the measure itself appears to be unworkable, impracticable of application, apart from its impolicy and even injustice. Now, in the first place there is no greater evil committed in the name of legislation and law than the placing of enactments on the statute-book which, on the face of them, are not expected to be worked or capable of application. The practice is one of the best possible means of educating the people to despise both the law and the Government and to cause neglect not simply of necessary demands under the particular measure which cannot be adequately enforced, but in regard to other and obviously more imperative obligations. If there is one direction more than another in which the Ceylon Government has failed—completely failed—to maintain or enforce its authority or collect its legal dues in the past, it is in respect of the so-called licenses which all Gem prospectors and diggers have been bound to take out before commencing their operations. Hundreds if not thousands of natives have for years deliberately scorned—and certainly never paid—these dues to Government. Even Europeans have been known to carry in gemming operations without any license—in some cases ignorant of the need of such restriction (so little has been made of it even in Sabaragamuwa) and in other cases through the difficulty of getting such a document in reply to application! At the time of the “gold rush” in 1881, regulations were hastily framed and in answer to the condition of a ten-rupee license being requisite for prospecting, a leading commercial house sent in the amount; but to this day no license has ever reached the hands of that firm, and not even the courtesy of an acknowledgment. If, therefore, there was room for reform at all at this juncture, it was in the direction of trying for the first time to enforce the comparatively simple and equitable regulations of 1881 and certainly until it was demonstrated that the new industry under European auspices was to be a success—until capital and machinery had secured returns, and until resulting dividends showed that wealth was being extracted from the colony,—it is the height of folly, perfect midsummer madness, for the Ceylon Government to put forth a measure which in its pretensions is calculated to stop the European gemming enterprise in its very inception, to drive away the men who have begun to take an interest in the industry and to strongly discourage a single British capitalist from investing his money in a country where the Government have, at the very first hint of such possible investment, made such unreasonable demands.

We trust it is not too late for the Government to abandon this obnoxious measure. To endeavour to extract a large percentage of the gross proceeds from gemmers, or gem digging Companies, is not only wellnigh, if not altogether impracticable; but it indicates great ignorance of the true direction in which the Government can fairly expect the revenue to be benefited. Surely Mr.

Wace and his superiors are not blind to the indirect, but very real advantages which would accrue to his province and to the general revenue—the Customs especially—from the initiation of a Gemming industry by European Companies? Apart from the proceeds of licenses or even a moderate levy per acre taken up by each Company, there is the very considerable outlay in stamps for every transfer and agreement made by such Companies. We are convinced that for the Government in addition to try and get a hold of a share of the proceeds in gems—or to hold such a claim *in terrorem* over the heads of any intending investors, is most unwise and impolitic, to say nothing of the injustice. For the last ninety years of British rule, we suppose, the natives have been extracting precious stones out of Crown land without even the shadow of a shade of such claim being made—at the very most a small license being levied—and that only collected in the case of units out of hundreds if not thousands of diggers. But now that European enterprise and skill are to be applied, the brilliant idea occurs to Mr. Wace—for surely neither the Attorney-General nor any other member of the Executive is guilty of the foolishness—of proposing an impracticable partnership in results. The inference would seem to be that the Ceylon Government would prefer to allow the Gemming country to be dealt with by natives in the future as during the past, and to see all European prospectors, experts and Limited Companies and their agents clear out of the place. If this be the explanation, far better to preface the new Ordinance with such explanatory clause, to run, “Whereas it is considered desirable to choke off any attempt on the part of London or Paris capitalists to develop the gem fields of Ceylon, Be it enacted”:

BECHE-DE-MER IN CEYLON.

Last Gazette contains, in addition to what we have quoted respecting Mines, a draft of Ordinance to consolidate and amend the laws respecting the collection, curing, storing and exporting of chanks and béche-de-mer. It is of a very stringent nature, requiring licenses for which fees are to be charged, while royalties are to be levied on chanks exported. The penalties for fishing without license, or for infraction of conditions, include imprisonment, simple or rigorous up to six months, with forfeiture of boats, carts, &c. Apart from the object of obtaining a fair revenue from the articles named, the main design, probably is the protection of pearl banks, and no doubt it is mainly with reference to this fruitful source of revenue that youths under 18 preparing to become divers by profession, can be exempted from license and penalties.

GRAFTING ON CUTTINGS.

This matter is touched upon in the October number of the *Garten und Blumenzeitung*, its advantages over the grafting of rooted plants with scions in a state of rest, and the good results of the method as employed by the French Vine growers in grafting European varieties of the Vine on American stocks being alluded to. It is well known that grafts unite with less loss in the case of some species of plants when they are placed on unrooted cuttings; the rooting of the latter and the union of graft and stock taking place simultaneously. It is the method commonly pursued with *Correa* varieties, using *C. alba* as the stock; with *Clematis* on *C. vitalba*, and with *Ampelopsis Veitchii* on the common Virginian Creeper. Examples are given of grafting weeping Elder on strong one-year-old matured shoots or suckers of the common Elder. These should be chosen of at least 6 to 7½ feet in length, cut across

just under a joint, and potted in 6-inch pots, the best time for the operation being the commencement of the winter. The soil should be covered with moss, and the shoot secured to the pot with string. The pots are then placed in a shed to which frost has no access, the grafts being placed in the stock by saddle-grafting in February, and secured properly with binding and grafting-wax. The cuttings are then brought into a house with a temperature of 65° to 70°, but which is not kept very humid, the stocks being sprinkled with a syringe but two or three times daily, and the young growth diligently cut off them, so as to prevent the drying up of the scion. In the same way it is stated standard Gooseberries may be obtained on long shoots of Currants, or *Ribes aureum* and *R. palmatum*.

As soon as union has taken place between stock and scion, as will be seen from the growth made by the latter, the plants are by degrees accustomed to a cooler air and ventilation, and stood out-of-doors in May. The pots may in summer be sunk in the earth, the latter being mulched with litter. In autumn the plants may be planted in the nursery. The above method of grafting is recommended for any plant which makes roots freely.—*Gardeners' Chronicle*.

CEYLON IN 1879 AND 1889:

COFFEE AND TEA.

In going over old papers we lighted on a letter by our correspondent W. A. T. written towards the end of 1879, but not published. We submitted the old letter to the writer, and he has returned it with his views of the change which has occurred in the decade and the outlook for the future:—

No. I.

Central Province, Sept. 13th, 1879.

DEAR SIR,—I have considered all along that it would need a rude shock to shake Ceylon men in their belief in coffee. Such a shock, however, is necessary; and such a shock is being now experienced. Why do we persist in sticking to a crazy ship? Who can deny now that our former staple can be compared to such. We have treated coffee with all the deference due to it, as the means whereby Ceylon has become what it is. But surely in the light of facts staring us in the face we cannot continue to do so.

Some years ago William Smith of Mattakally warned us to turn our attention to tea and cinchona; and, I ask you, have subsequent events proved he was wrong? It is only the fortunate few who have possessed fine land in a fine climate who have made money by the cultivation of coffee. I exclude speculators. A great deal of money has changed hands in speculation in coffee property—especially in the younger districts. But cannot speculation, the healthier sort, be carried on as well, even better, in cinchona? In cinchona the out-turns can be more confidently anticipated; and therefore speculation in standing crops, and in the cutting and curing of the same, will afford a brisker flow of trade and money, than is the case of the present stagnant state of the coffee enterprise.

Cinchona cultivation requires less labour, less appliances, and less supervision, and therefore less expenditure.

Look what "high cultivation" of coffee comes to. It is heart-breaking to think of the thousands of valuable rupees daily sunk in maintaining a diseased and comparatively unproductive plant. Wearisome weeding! High-pressure manures to afford fuel to the accursed flame of *Hemileia*! to make luxuriant foliage to be torn off by relays of pruners and handlers! Buildings up and pullings down! Costly maintenance of bovine herds, for what? For the production of crude manure to be washed by the monsoons to the rich fields of the Government-pampered villages below.*

* Largely true: but the cry now is that the poor villagers have been deprived of irrigation water by the forest clearances of Europeans!—ED.

To anyone travelling about the coffee districts, the general unsettled, discontented air of the men he meets could not but be apparent. There is not a superintendent sure of his berth; some are not sure of their pay; have their hands tied in carrying out necessary works owing to the pressure of the time. If this is the case with superintendents, you can believe that proprietors are not much happier. The fall of "Houses" and the mutterings of the storm have brought proprietors out with a rush, displacing good tried men, who are thus thrown out of employment. Altogether it seems as if the "crisis" be near, and then—what have we? Sad ruin to many and deplorable distress; but anxiety over—the worst known, and is not that better? And afterwards the calm! cinchona and tea in the higher altitudes, cacao in the lower, Liberian coffee in Liberia, Arabian coffee in Arabia!

You may say that I am too summary in my disposal of coffee. You may instance the cases of potato blight, and vine blight; but I reply that neither potatoes nor vines, in health or in disease, can be compared to coffee. Potatoes and grapes are severally cultivated by a people dwelling in the country of their fathers, to whom the cultivation of any other product would be a species of heresy. Their fathers before them lived by this cultivation, and no arguments save absolute sterility would ever persuade them to change it for something else. Thus both blights were combated with for long. The people were assisted in every way by their Governments, and some success at last attended their efforts. Now let us come to coffee. It is cultivated by men who have come across the globe to a country where nature forbids them to "multiply and replenish the earth," where no permanent settlement can be made as in America, Australia, or the Cape. Their object then is to make money speedily and quit the country. Is it so likely then, that the campaign against blight will be so combinedly and energetically pursued?

And if it has been so to a certain extent, what help have we experienced from Government? Ours is not, as in the case of the Governments I spoke of, a Paternal Government. It is a Government steeped in Official Ink, beswaddled in Parchment, and bound hand and foot with Red Tape! The departure of Mr. Morris offers a deplorable instance of the kind. I ask your readers to turn to the lucid narrative of Mr. Shand. How ineffably disgusting was the whole affair! An able man comes to Ceylon to assist Dr. Thwaites in his efforts to keep up wonderful correspondence and exchange of plants with other countries—useless fiddle-faddling amid the shadows of trees whose age testifies to the length of time wasted and money spent. This able man sees at once what his duty is. He is heard of very soon amid the assemblies of Planters. At last he is proclaimed a doughty champion who has entered the lists against the red-spotted *Hemileia*! And he proves no empty braggart. But!! Ye gods and little fishes! Tell it not in Galle! Whisper it not in the Fort of Colombo! Just as the enemy was being worsted, when it was merely a matter of time, our champion was tempted away, in fact had on alternative, and our cursed enemy is still at large!

Let this enemy range at will amid the gardens of the heathen, let him fiercely ravish the sickly plants sprung from animal deposits, let other climes supply the fragrant cup to dwellers in the north. We can laugh the fungoid fiend to very scorn in cultivations his rusty finger cannot harm. We can stroll amid our cinchona or cacao groves which will soon enable us to stroll along the sweet hedges of England or climb the bonny heather hills of Scotland; and far from blighted fields, where hope deferred sickens the anxious heart, enjoy thoroughly, and realise what it is to be at home. W. A. T.

No. II.

21st Jan. 1890.

A great deal has happened since 1879. Tea is understood so well that we have sent men to the Indian tea districts and have had hardly any Indian men to show us the way. The day is long past the experimental stage. Armstrong and Owen are counted as

behind the age, Rutherford is no longer a leader, and each man doeth what is right in his own sight, knowing his work as in the old coffee days. The coolies have become familiar with the flying rollers, and whirling belts, and grimy firing machines, and even the engine, room has lost its wonders. The power of steam and adoption of machinery has proved a wonderful educator of the natives. Field work has become but a regular routine, and every coolie boy knows every move in the game. Those planters who had former experience in coffee and field work generally have found it rather to their advantage to have delayed acquiring tea experience, as they avoid all the circuitous wanderings and step straight into the middle of matters armed with the Planters' pocket-book, and furnished with trained coolies and ready found machinery.

The old coarse plucking has been given up; and up-country men study flavour, lowcountry men study "point," medium elevation men study the main chance, and all are as keen as ever to give or take a "wrinkle" from his neighbour. I am glad to see those prize essays and lectures given up. Each district, nay each estate, nay each field, has its individual characteristics, and it is only the manager who is in touch with the market through the medium of his own manufacture who can really judge. At present the market is in favour of lowcountry growths, a strong liquor with pungency and "point" being desiderated, and this in the lowcountry can be had by *no* fermentation. Upcountry growths are flavoured but weak in liquor.

To leave tea I would point out that even supposing there comes a day of adversity I can see a great field for the ever-undaunted Ceylon planter. I see all the northern part of the island and round to Batticaloa under cotton with machinery and bungalows. I see a large tobacco enterprize. Depend upon it Ceylon will not founder. Who is the "James Taylor" of the coming cotton enterprize? The extension of tea in the lowcountry proves, how well planters thrive there. Then there is the *Gemming Boom*. Many fingers will be burnt over that pot—but you will yet see the gem factory surrounded by high palisades, guarded by fierce bulldogs, entered only by naked natives, and fitted with machinery not only under lock and key, but under the stern eye of the well paid and intelligent European. Imagine big pipes carried through the palisades into large rooms in which are rocking and spinning basins (a cross between a sugar *vacuum* pan and a "Rapid" roller), the water splashing and dashing through the machinery, and the precious "eeelan" being thrown in by buckets on an endless chain fed from an underground store. The sediment then would be shot down into another underground floor where no natives should be permitted to enter. All this is in the future, but don't forget the bulldogs or the palisades.

Cacao is a small profitable product suitable to a limited area.

Cubeb is a mine of wealth if you could get the true article.

Coffee might be a profitable product if cultivated in suitable localities with full attention to husbandry and shade.

But let the planter persevere with tea till Nature holds her hand; and when blights come, the lowcountry can be over-run with cotton plantations; and it will only want a palm-leaf hat, pyjama suit, big collars and a banjo to complete the picture of South Carolina. Ceylon planters will never be driven into the sea. Shall I be spared to give you my views in 1900?

W. A. T.

[We hope so; but our correspondent's character as a prophet is somewhat qualified by the collapse of cinchona.—Ed.]

"COLONIA."

"Colonia" is the title of a new venture in connection with the Colonial College, Hollesley Bay, Suffolk, the Principal of which is Mr. Robert Johnson. From an article on the origin of the College, we learn that a proposal to found an institution to be devoted to the

object of training youths for colonial life was made in 1884-5, and the favourable opinions expressed by eminent colonial men as to the necessity for such a college led to its opening in 1887 but with only 3 students. This number has now increased to 65, and since its foundation some 32, to judge from the directory of old boys, have passed through the collegiate course and settled down in various parts of the world—three of them having come to Ceylon and established themselves at Kadugannawa, Dimbula, and Maturata. The great advantages of a term of residence at such a college are that students will be able to discover whether they have any aptitude for colonial life, if so in what direction, and whether they will be constitutionally fitted for one or other of the various climates all about which they will get to know; that they will have opportunities of going abroad with friends, and will have a connecting link through the college with other colonists. The old students' column consists of contributions from the various colonies where the students trained at Hollesley Bay have settled. One writes of tea-making in Ceylon, another of the discovery of an auriferous quartz reef in South Africa, another of farming 3,000 acres at Cape Colony, another of land clearing in Canada, and still another, who has evidently started on a large scale, of having 30,000 sheep and 15,000 head of cattle on his estate in Buenos Aires. Dr. Taylor, who is well-known as the editor of *Science Gossip* contributes some "Australian Notes." He refers to the discovery of a five feet seam of coal, in Victoria, which he says is perhaps worth more than all its gold-mines put together. He considers it a mistake for young men to think that they are going out among a rough and ignorant lot in the Australian Colonies, and speaks in high terms of the refinement and culture in Australian houses. The State Schools, which are redistributed all over the country, are free; and in some of the colonies the pupils are carried to and from school by the State railways at no charge. The Australian colonies, says Dr. Taylor, do not require doctors, lawyers, surveyors or engineers. "The best outfit a young fellow can take with him is a healthy constitution, willingness to work and to go anywhere to work if necessary, and sober habits. If he can take a little capital with him all the better—particularly if he has sense enough nor to spend it, but to take care of it until the inevitable favourable opportunity turns up. "Orange culture" in Orlando, Florida, gives a short sketch of the method of cultivation and winds up with a calculation showing that after the trees have been fully established, a profit of 200 dollars an acre is a reasonable estimate. "I feel sure," says the writer, "that a fellow who is willing to work hard and steadily and keeps his eyes open will get on, and it is as jolly a life as one can wish for." T. H. Rutherford gives a chatty account of a new chum's life in the land of the Maori: J. D. Telford writes on Imperial Federation from an Australian student's point of view, which is not a favourable one, and agricultural, dairying, veterinary, surveying, and college notes fill the rest of the number. It may be safely predicted that the new venture to judge from the first issue (which by the way has seen to a second edition) will be a great success, for while it circulates useful information for those it is intended for, it will be a happy medium for the interchange of ideas and the discussion of interesting subjects, a strong link that will bind the new colonists to each other and their *alma mater*: while its best work will be the dignifying of labour, the developing of energy, and the fostering of ambition.

A NEW TANNING SUBSTANCE.

[Some months ago I remember you had a leader on some Ceylon trees, the bark of which was said to be suitable for tanning purposes. Here is something.

—Cor.]

Experiments have been made recently in Newark with a South American bean called the "Angola" with the view of substituting it for gambier, but we understand that the tests were not satisfactory. This

new material has been offered at one cent per pound less than gambier, and New Jersey tanners imagine that they had been put in possession of a valuable addition to their raw materials until the trials demonstrated that gambier could not be substituted so easily. The importation of the peculiar bean has practically ceased in consequence, and South American houses have been requested to pursue their investigations further in the hope of obtaining some new product which would be of value in this line, as there are times when it is desired to prevent the fluctuations in gambier by pushing an article to take its place. Some attention is being directed to the canaigre root, which was described in *The Reporter* of September 4th, but great difficulty has been experienced in obtaining supplies from Mexico. The inquiries come from tanners, but thus far they have not been satisfied, and it is questionable if a cheaper article than gambier can be found to meet the same requirements.

GEMMING IN RAKWANA.

(FROM OUR MINING CORRESPONDENT.)

Jan. 31st.

EUROPEAN EXPERTS AT WORK—NATURE HAS DONE FOR GEMS WHAT SCIENCE CANNOT DO—THE CAUSE OF FAILURES—GOOD AND BAD "ILLAN"—ANCIENT GEMMING BY INDIAN PRINCES AT RATNAPURA—GOVERNMENT INDIFFERENCE TO THE INDUSTRY.

Mr. Harding has arrived at Ratnapura and has been joined by Mr. Barrington Brown, who came from Rakwana to meet him. They have been engaged for some days past examining the strata of gem gravel on the different lands secured by the Syndicate, and intend to proceed to Pelmadulla and Balangoda in the course of a day or two.

There is no doubt nature has done for gems what science cannot, viz. decomposed the matrix and allowed them to find their level in the alluvial deposit of valleys and river beds, where they have been lying for centuries, some worn by long travel and others almost in the same shape and form of crystals as they were formed, and left their original rock matrix. One of your contemporaries says that gemming has been carried on so many years under the eyes of Europeans of great sagacity, and even on their own properties, in the most favourite localities, and had they succeeded, local companies would have been started, also that they have invested largely in the Burma Ruby Mining Company, &c. &c. Now who are those Europeans, I would like to know? I think your morning contemporary (who admits that he knows nothing about gemming) had better stick to the Grain Tax, National Association or something else, instead of starting upon gemming at this late hour, after the subject has been so thoroughly thrashed out in your columns.

Europeans have been satisfied with their agricultural interests, and superintendents were debarred by proprietors of estates from gemming on their own account in Rakwana and Balangoda districts, and it is only lately (since coffee and other products have failed) that any European has thought of gemming. Now about local companies. I can assure your readers that they have been at work for centuries and are still at the present day. Whenever a good gem has been found on any rich illan discovered, a native company is formed, and the place is worked till every inch of the ground is turned over and in many instances large fortunes have been made.

Everybody of course does not know good "illan" when they see it, and it requires the practical miner to find it out. Then who, pray, are the Europeans who know anything about good or bad illan? Natives who have seen the results from good and bad illan and have made a special study of gemming can tell it, but there is not, to my knowledge, any European in the country who knows good illan from bad, and they would be just as willing to work a barren illan, as a rich one, which perhaps has been the cause of the failure of one or two Europeans who have tried their luck on a small scale in Rakwana

lately. In the Ratnapura district there never have been resident Europeans, except Government servants, who are prohibited from speculation, but native companies have been at work about Ratnapura, since the right to gem was conceded to them after the king of Kandy was captured, before which the kings used rajakariya labour. Indian princes came to Ratnapura for gem digging with Tamil labour hundreds of years ago, and in the illan about Ratnapura we sometimes find ancient Tamil jewellery and pottery, which signifies that Tamils were at work ages ago I believe brought over from the Coast for the purpose of gemming. The natives never know good gem land till it has been tested, and do not exercise the same precautions as a practical, judicious miner would, in selecting land; such as studying the flood outlets, the bars on the hillside, the old and present course of the streams, the nature of the rocks above where the gems have come from which doubtless accounts for so many unsuccessful prospecting pits. It takes a very careful intelligent European 12 months' study to know good land from bad, even with the aid of geological knowledge.

The experts now at work have too sound a reputation at stake to dream of forming an opinion on anything but facts based upon actual results of prospecting openly; and the British public who may speculate in gemming in Ceylon may feel confident that they are not being misled or deceived in the slightest degree by the scientific practical men they have confided in; who are sparing no time or trouble, and leaving no stone unturned, to ascertain the main point at issue, viz.—will it pay?

Messrs. Armitage and Fahey are at Rakwana prospecting and Mr. Biddley is still at Balangoda. Not one acre of land has been taken over from Government, and it is not likely to be, although many hundreds of acres—yes thousands—are offered, and are being leased from natives. A Government official was heard to say the other day to the representative of a company:—"We don't want a lot of *navvies* in our newly inaugurated Sabaragamuwa Province." I would very much like to know who the Ceylon men were who bid for the lease of the Burma ruby mines *re* "Independent." It has been discovered now that rubies cannot be got out of the limestone matrix without cracking and otherwise damaging them. Nature has done for us what dynamite, fire and chemicals cannot.

VITICULTURE AND WINE-MAKING IN THE SOUTHERN DISTRICTS OF QUEENSLAND.

(From the Annual Report of the Department of Agriculture for 1889.)

MR. SEARLE'S VINEYARD.—I visited this vineyard and went carefully over it in company with the proprietor.

The township of Mitchell is situated on the western bank of the Maranoa River; the surface is flat, of a siliceous formation, and the soil in Mr. Searle's vineyard is a fair sample of the surrounding district.

Although, as Mr. Searle admits, he is but an amateur viticulturist, he appears to be possessed of a good deal of common sense, and is quite aware that it is not sufficient for the growth of vines to dig a hole and stick a vine into it, or to plough the land shallow and then lay out the vineyard and plant the cuttings. All the ground in this vineyard is trenched to a full depth of 2 feet, the soil well turned up to the weather, and by these means a good crop of fruit has been secured even in dry weather. At the time of my visit his vines looked remarkably healthy, and were heavily laden with fruit. The vines are planted well apart, affording plenty of space for light and air.

In training the vine for fruiting purposes, different growers have adopted different systems, without regard to the nature of the plant. Some adopt the "trellis" system, others again simply tying to stakes; while at one vineyard at Roma the owner, Mr. Twine, has, with some of his vines, adopted what is called the "goblet system," which is accomplished by taking a long fruit vine, bending it round in arch form, and tying it back

to the main stem. For convenience in working the ground and keeping it clean, the stake or goblet system is preferable to the trellis; but, on the other hand, a larger quantity of fruit is secured by the latter system. Mr. Searle has adopted the trellis, as it answers his purpose very well with the small area of land he has under cultivation, and which can be easily worked and kept clean.

As knowledge of the nature and habits of the grape vine increases amongst the viticulturists of this colony, it will doubtless be found when viticulture has become a fixed industry that different varieties of vines require different varieties of soil.

In the Mitchell district are to be found different classes of soil—rich, deep loam, scrub land of volcanic formation, and sandy soil well drained, and yet retaining sufficient moisture to develop the fruit even in such a protracted drought as the district was suffering from at the time of my visit.

Although Mr. Searle is but an amateur, he has got hold of the correct idea that by grafting he can increase the hardiness of his vines and secure a better class of fruit. As yet he has experimented with only one vine, but to judge from appearances his graft has been a thorough success.

Grafting is a matter that the viticulturists of this colony cannot too soon devote some time and attention to, for it is a well-known fact that by grafting the more delicate vines on to stocks that have proved themselves more able to resist the diseases that grape vines are subject to in this colony, the better chance there is of securing a crop than by growing direct from the parent stock. And there is another point which must also be kept steadily in view: So far, Queensland has been exempt from the dreaded *Phylloxera vastatrix*. As this disease has already attacked some of the vineyards in New South Wales, it may almost be looked upon as a certainty that at no distant day this disease will visit Queensland; therefore it behoves every viticulturist to commence without delay raising resistant stock on which to graft the weaker kinds, which would be more liable to attack by this enemy to vignerons.

BASSETT'S VINEYARD—Mr. Bassett's vineyard is situated about 1 mile from the town of Roma. The soil is of a loose, sandy nature, evidently well adapted to the growth of the grape vine. The area under crop is about 60 acres. Mr. Bassett states that, like many others when first entering upon this industry, he was possessed of very little knowledge of grape vines, or the proper method of laying out a vineyard, consequently, after planting the first portion, he found that he had placed the vines too close together, and the rows also too near to each other—viz., 5 feet between and 4 feet in the rows.

In the second portion of the vineyard planted he improved his system of planting by placing the vines wider apart—viz., 6 feet in and 5 feet between the rows.

More experience was gained by his second planting, the result being that in the last portion planted he adopted what he considers to be the proper space in the Roma district—viz., 10 feet between and 6 feet in the rows.

In preparing the soil for the vines, the land was ploughed in the usual manner to a depth of 6 or 7 inches. This shallow ploughing may be sufficient for the loose sandy soil around Roma, but I am of opinion that even in that class of soil considerable advantage would be gained by a subsoil plough following the first plough, thus bringing the soil under the mellowing influence of the atmosphere, and which would undoubtedly prove beneficial to the grape vines, especially young vines.

Mr. Bassett has adopted the stake system in his vineyard, and having such a large area of ground to work, he is probably right in adopting this system.

Although the trellis system has many advocates, tillage is greatly facilitated with the stake system, by allowing the use of horses in keeping the ground clean, and in stirring up the soil both along and across the rows. The hoe can then be used in clearing up near the roots of the vine.

I learnt from inquiry that, except in close, muggy, wet weather, the vines in this district are seldom

attacked by oidium, and when attacked the fungi gives way readily to an application of sulphur mixed with fine ashes. This freedom from disease is, no doubt, to be attributed to the absence of the humidity which induces the disease in the coast districts. Black spot occasionally appears on the vines, but not to such an extent as to do any serious damage to the fruit.

LEACH'S VINEYARD—On my journey back to Roma I visited the vineyard of Mr. Leach, which is situated on a ridge, with a fall to the east, west, and north. The soil is a strong, reddish loam of a calcareous nature, and in my opinion, strengthened by the appearance of the vines, this is the best class of soil in the district for the grape vine. The land was broken up with a bullock plough 17 inches deep, harrowed, and then cross-ploughed to the depth of nearly 2 feet. The effect of this treatment tells its own tale, as in no part of the Roma district did I see such healthy vines, and showing such a large crop of fruit. Altogether there are 26 acres under vines, one-half being vine grapes and the other half table fruit.

REGULATING THE SALE OF TEA.

In compliance with the request of the Indian Tea Districts' Association, the selling brokers interested held a meeting on January 3rd, 1890, at the offices of Messrs. Stenning, Inskip & Co., and it was resolved: "That they will endeavour to regulate the sales, so that for the month of January not more than 35,000 chests shall be printed each week, and not more than 15,000 chests in one day. And after that date for this season a much less quantity will have to be printed per week as the quantity on hand to be dealt with will be smaller."—*H. and C. Mail*, Jan. 17th.

HOW COTTON PAYS IN AMERICA.

Mr. Bolgard, of Bavon Rapides, up to last week had gathered 28 bales of cotton from 24 acres, (the bales averaging each 502½ lb.) and still had in the field, as estimated by Mr. Kincaid, 5 more bales, making 33 bales, or 16,500 lb. of lint cotton to 24 acres.—*Town Talk*.

Mr. John Sample, of Picavunneville, takes the cake this year as the boss cotton farmer. He bought in the spring of the year, cotton seed, the Southern Hope, of Mr. E. J. McGhee, of West Feliciana, and planted six acres, from which he has already gathered five bales of cotton, two of which weighed 512 lb. and another 415 lb. which were sold for thirteen cents per lb. The other two weighed respectively 540 and 425 and sold for fourteen cents per lb. The cotton was sold by Messrs. Harris, Day & Co., of New Orleans. In addition to his cotton, Mr. Sample has sold 13 sacks of seed, at three dollars per sack, and has some ten sacks yet to be disposed of.—*Point Coupee Banner*.

THE VALUE OF LAND IN THE TRANSVAAL.

The enormous increase in the value of land in the Transvaal Republic is shown by the following fact communicated through the "Volksstem" (*Vox Populi*):—Two years ago a building lot in Johannesburg was bought for less than £30. This same building lot now forming part of the site of the vast structure of Malcoms & Co. in Commissioner Street has just been resold for over £30,000. Amongst the most important buildings in Johannesburg being certainly the Palace Buildings. These lately completed structures are esteemed the finest in the town. They are intended for merchants' offices, stores, and shops; whilst the third stories are to be fitted up as sleeping apartments. At the corner of Pritchard St. and Rissik St. is formed a lofty clock-tower, the flagstaff at the top is 93 feet in height above the ground floor. The clock has four faces, and will be visible from all parts of Johannesburg.—*Indische Mercur*, translated by J. D. Y. for the *Observer*.

Correspondence.

To the Editor.

TEA PLUCKING—A QUERY?

DEAR SIR,—I shall be much obliged if you, or some of your readers, will tell me—What is generally understood by “plucking once in eight days.” For instance, if a planter who says he plucks “once in eight days” commences a round on Monday, January 1st, when would he commence the next round?—Yours faithfully,
INQUIRER.

[On Tuesday, January 9th, surely?—Ed.]

THE GAME PRESERVATION MOVEMENT.

Jan. 22nd.

DEAR SIR,—I am glad to see that the Matale Association is not going to be allowed to carry on the Game Preservation movement singlehanded, and I trust that Mr. Armitage's call will in due time receive a hearty response.

I see that Mr. Armitage fixes the 1st February for a meeting of any who may be inclined to support the movement. I recognize with him the necessity for immediate action. I think however it would be well to postpone any general movement until the result of the Commission which His Excellency proposes to appoint has been made known. It will be acknowledged that no unofficial action could exercise any control over the agencies which are the cause of game extermination. This being the case, it would surely be advisable to await the results of the official Commission. We have been given to understand that the matter is to come before the Legislative Council at no very distant date, and it is quite possible that the action hereafter to be taken by the Government Commission might stultify the action of the proposed unofficial movement: we should in fact have to work in the dark, not knowing how far the Government would support our action. I would suggest, therefore, that no meeting be held until we have been made fully acquainted with the proposals of the Commission. I would point out *en passant* that one of the reasons adduced for forming a Game Preservation Society does not exist. There is a close season, a very well chosen one; we do not require a new one, but the enforcement of the existing one; but apart from this there are excellent reasons for the formation of a Society such as is proposed.

What I desire to point out is that we cannot move in such a matter without official sanction. The first shipment of rabbits might be “stuck up” by the Collector of Customs. The only satisfaction the members of the Society could obtain would be perhaps the permission to course the cargo (costing a guinea a head) with fox-terriers on Galle Face!—Yours faithfully,

E. GORDON REEVES.

“GREEN” TEAS AS MADE BY MR. DEANE.

Kintyre, Maskeliya, Jan. 24th.

DEAR SIR,—With reference to Mr. F. F. Street's spontaneous and therefore all the more appreciated report on my green teas, I can only say that in due course I shall be glad to show any one the system of manufacture. I am awaiting the result of my first large break before publishing Mr. Street's reports, and also wish to secure my patent for a certain necessary machine. Samples of my break went forward by the S. S. “Rohilla” to London, and the break itself of some 2,500 lb.

is about to follow. Should the introduction of this class of tea prove of service in opening a remunerative trade with America; no little thanks will be due to Mr. Street who has had I fear considerable trouble in reporting on various green tea samples for me for quite a year, and encouraging me to continue my experiments, which at length appear likely to be successful. Should this be the case there will be no longer the fear of insufficient withering accommodation hindering work as by my process the leaf becomes made tea within three hours of its entering the factory.—Yours faithfully,
H. D. DEANE.

CEYLON TEA IN NEW ZEALAND.

SIR,—The enclosed letter from Mr. J. V. Owen will, I am sure, be read with pleasure by all interested in our tea industry and its representation at the Dunedin and South Seas Exhibition. It shows how much we are indebted to our old friend Mr. Watson for the interest and trouble he has taken in representing us. I have just written and sent him our very cordial thanks.

L. H. KELLY, Chairman,
Ceylon Planters' Association.

Castlereagh, 20th January 1890.

Enclosure.

Dunedin, New Zealand, December 9th, 1889.

My dear Kelly,—I have been intending to write to you some time past, but until now I have scarcely had any leisure time, having been so entirely occupied in doing the sights in this lovely country, and, last but not least, in doing the Dunedin and South Seas Exhibition. I very much wish I had been able to come here before the opening of the Exhibition, as then, perhaps, I might have been of some use to Mr. Watson in his arrangement of the Ceylon Kiosk. However, my intervention would have been superfluous, as he has so admirably and efficiently carried out the wishes of the Ceylon Planters' Association, and indeed more than fulfilled the very onerous duties which he had so kindly undertaken for us. To give you and others in Ceylon a better idea, however, of the Kiosk than any written description could convey, I took two photographs of it, and had some prints taken from them, which Mr. Watson will forward to Messrs. Ferguson* and yourself. The space was naturally very restricted in and about the Kiosk, so that a more comprehensive photograph could hardly have been taken. In the centre you will notice a trophy composed of tea samples, in small boxes, amongst which are to be found Vellai Oya, Theberton, Tommagong, Kintyre, &c., &c. teas, white here and there are spaced photographs descriptive of the various processes in tea planting and manufacture; below is a model of a Sinhalese hut, a chekko, and a cart and bullocks; the whole surmounted by colored grass Kalutara boxes; to the right and left, in front, are the Kandy Art Association exhibits, which by the way are extremely highly priced and I fear will not sell while around the central trophy are placed the tables for tea. The Kiosk itself is very nicely finished and hung with yellow curtains, and with the pillars of blue, yellow, and gilt, and the extremely neat lettering descriptive of the object and inception of the Kiosk, the *toute ensemble* is remarkably good. There are two side wings which are hung with mats, fans, and a series of Ceylon photographs taken chiefly by Soowen. At the back curtains are hung, behind which the servants prepare the tea. Mr. Watson has, no doubt, kept you informed as to the financial part of the profit. I am glad to learn it is so successful in this respect, and that there is at present a considerable profit on the sale of tea in the cup. Up to date the expenses are, roughly, £7 10 per week, and the receipts about £2 per diem. The Kiosk is greatly in request by ladies for giving tea-parties in the evening, and although, perhaps, this may not pay, still the results as to advertising Ceylon tea are great. Naturally, taking so great an interest in Ceylon

* We have had ours mounted and circulated through the Fort.—Ed.

as I do, I have spent a great deal of time in the Kiosk, and from observation, extending now over some days (8), I am able to state that the number of visitors coming in for tea is greatly on the increase. I am not aware what the financial result attendant on the establishment of the Kiosk at the Melbourne Exhibition was, but I believe it resulted in a loss. I do not think that there will be a deficit in this case, indeed, I should say quite the reverse, especially when the X'mas months are taken into consideration when a great influx of visitors may be expected. I am sure we should all be very thankful that Mr. Watson and his very efficient Manager, Mr. Begg, were on the spot, and it is needless to say they have done wonders.

The tea sold is mostly Mariawatte, I think. It seems a pity a more flavory tea had not been sent for the Kiosk, as, although the tea is remarkably good, still an addition of a higher growth might have resulted in a better tea, at any rate for drinking in the cup. There are several importers of teas here, but few import Ceylons. A firm here, by name Nelson, Moate & Co., have a tea trophy near the Kiosk, and impudently advertized "Ceylon teas." It is impossible to discover any Ceylon tea in any samples I have tested, although I purchased some Sinhalese tea, so-called, sold by this firm. I had a very amusing interview with these gentlemen, and gave them I can assure you, a very unpleasant quarter of an hour, enlarging on their boldness in selling tea in which we could not detect Ceylon tea, although Mr. Begg and I both put it to every test we could. I am sending you a sample of this, also of a "Jumbo" brand (save the mark!) said to be composed of Indian tea. The "Ceylon tea" or "Sinhalese tea" is sold at 2/3 per lb. Nos. 1 and 2 "Jumbo" at 2 and 2/3. I enclose some advertisements cut from the local papers I think the barefaced statement that Ceylon tea is "sickly" should be strongly animadverted upon by Mr. Ferguson in his paper. I have not seen any copies of the "Observer" here except at Mr. Watson's. The servants are doing very well and were glad, I think, to see a Ceylon man who could converse with them about their fatherland. They live at Mr. Watson's in a comfortable little house here, his own domicile. They certainly attract a good deal of attention and draw visitors who might otherwise pass by.

The Ceylon and Indian Tea Association have exceedingly nice premises in Prince's Street in a fine building, and with a fine large plate-glass window, so that Ceylon teas are well advertized there to numerous passers-by, as Prince's Street is the street of Dunedin, and I think this venture will prove a very successful one to the shareholders. The opening of this Company has given great offence to some tea-dealers, notably to my friends Nelson, Moate and Co., who have carried their ill-feeling even into the public papers.

The Exhibition is a very decided success, and to anyone not acquainted with New Zealand or indeed Australasia it would be a revelation, shewing what enormous strides these colonies have made during the last 20 to 30 years. The manufactures in iron work, agricultural implements, pottery, glass, woollen and textile fabrics are simply wonderful; indeed there is little which is not equal to and in some cases better than English manufactures. Many people state that this is better, as far as exhibits go, than the Melbourne Exhibition. The expenses are only £300 per week, and Mons. Joubert prophesies a very handsome surplus at the close in April.

I have no doubt in my further travels I may come across more "Sinhalese" and "Jumbo" teas, in which case you shall either have samples or hear from me concerning them if I cannot procure samples. I append a list of exhibits at foot. The trophy will be taken away shortly, when the judging takes place, and will give room for two more tea tables. I imagine all "fancy" teas will be judged, and I do not think from what I can gather that the teas will be classified. Who the tea judges are to be I know not. I apprehend it will not be an easy matter to get perfectly unbiased jurors.

J. VEBE OWEN.

The following is one of the advertisements alluded to:—

"BUY JUMBO."

The Jumbo Blends,

No. 1 and 2 at 2s and 2s 4d.

Are superior and more regular in quality, better liquoring and less distasteful.

To those who are at all inclined to biliousness than any original packages of Indian or Ceylon Teas imported.

As all Indians and Ceylons are sickly and most irregular in taste, we strongly recommend those who cannot drink them trying these pure uniform Blends.

"JUMBO."

Specially prepared and packed by Nelson, Moate & Co.

CINCHONA:—CANKER VERY BAD AND THE GOOD OF A SYNDICATE.

Lindula, Jan. 25th.

DEAR SIR,—The other day a Lindula correspondent wrote you that canker in cinchona was less prevalent now than 10 or 12 years ago. My experience (a pretty large one) is that in 1878-80 canker was almost unknown here, while now trees are dying by thousands where there are any still left. Again he says that the Syndicate will not do much good for the reason that as long as the buyers know that there are so many healthy trees still growing they will continue to keep the price down. To my idea it is exactly the other way. The grower has the whip-hand as long as his bark is untouched. He is gaining in quantity and, probably, quality.

The contrary is the case where the bark is harvested, as the buyers can easily find out what quantity is being stored and they know that the grower must sell sooner or later and is steadily losing every day he holds.

The Syndicate must do some good, though it has been started rather late, but not so much as if we could restrict the quantity to be harvested as in Java, but that is not feasible here.

Very cold nights and frosty mornings. Coffee is looking well in parts and another good crop ought to result when it is cultivated by itself.—Yours truly,
70,000 LB. CHIEFLY FROM CANKERED TREES.

THE MEETING TO PROMOTE GAME PRESERVATION.

Nuwara Eliya, Jan. 25th.

DEAR SIR,—I have read Mr. Gordon Reeves' letter, but I do not see why the meeting fixed for the 1st February should not come off, for the following reasons:—

1st.—The meeting is simply called to see if sufficient support can be obtained for further action in the matter.

2nd.—To appoint a Committee. This Committee would recommend to the Association how the money collected should be spent, and this would of course find out first what views Government had on the matter, especially before bringing out rabbits.

3rd.—Mr. Reeves says a close season exists. This statement unless I am much mistaken is misleading. For I am under the impression that the present close season only applies to one or two provinces, and certainly to only one or two animals. For instance, are the hares, partridges or jungle-fowl included under the present close season?

4th.—I think that the Committee of the Society which is being started could do a great deal to help the Commission with advice from their numbers and experience all over the country. I may say that many names have been sent in, quite sufficient to form a nucleus for the further extension of the Society, and that of these there are some of the keenest sportsmen in the country who I have little doubt will do their best to work with the Government in whatever way the Commission may suggest, so far as it effects the better preservation of game.—
I am, sir, yours truly,
H. P. C. ARMITAGE.

THE PROPOSED NEW TAX ON GEMMING.

Colombo, Feb. 4th.

DEAR SIR,—It has long been known that the present Government is antagonistic to European enterprise and to the introduction of European capital into the island to develop its resources and increase its wealth.

As an illustration of this I have only to point to the hot haste with which it has cancelled the moderate and reasonable mining and gemming regulations of the 16th December 1881, under the protection of which capitalists have been induced to subscribe large sums, and to enter into extensive contracts to bring to light the hidden riches of the island, and to the publication of an ordinance in substitution of the cancelled regulations which, if it became law, would put an immediate stop to the search for precious minerals in private lands, which is now being commenced for the first time by Europeans in a serious manner.

From time immemorial the natives of the island, as is known all the world over, has been successful searchers for precious stones, not only in private but in Government land without let or hindrance. The Government has over and over again admitted its inability to stop their lawlessness, and they will continue in the future, as in the past, to circumvent all efforts to interfere with their favorite and exciting pursuit.

The idea of obtaining a share of the gross value of native pickings, could only have emanated from the brain of the latest Civil Service cadet. As it is the idea is simply ridiculous.

Though the contemplated blow is intended to be struck at natives as well as Europeans, it will fall comparatively harmless on the former. The Government Agents with all their assistants could scarcely watch the output of every pit sunk by native; but it might just be possible if the "illan" raised by Europeans was only allowed to be washed periodically, for an official to be present at each washing to clutch the proposed Government share before it is made away with.

When the Government sold its land, it undoubtedly reserved its right to the precious minerals in the soil, but as it could neither raise them itself, nor grant the right to anyone else to do so the value of the hidden wealth to Government is insignificant. Insignificant as it may be it should undoubtedly be paid for, by those who wish to acquire them; but the price should be commensurate with their value *in situ*.

A trifling royalty as provided by the cancelled regulations, and the direct increase to the revenue from the stamps on transfers and leases, would amply compensate Government for the surrender of its rights. But that the Government does not intend to be satisfied with the terms claimed by the Government of all civilized countries unfortunately admits of no doubt. Under the provisions of the Ordinance now published a heavy and probably an overwhelming tax is to be laid on all gemming. How much it is to be or in what form it is to be levied, it is impossible to guess from the Ordinance as published. If it is to be 10 per cent of the gross value of the precious minerals, it will probably swallow up the whole of the profits. Whatever may be the returns to the shareholders who provide the capital to bring the "illan" to the surface, the Government will at any rate realize the handsome income of 10 per cent on the value of the gems without outlay or risk.

As however this form of levying the tax will be found to be impracticable, and easily evaded; the alternative method of an annual rent on the land will have to be adopted; and if we may judge what

this will be by the other proposal, it will be a swampy one. Whatever it may be it is to be left to the discretion of the Government Agent, who is not only to be omnipotent as regards the tax, but also in dictating the terms on which licenses are to be granted to search for precious stones on private lands for the purchase of which high prices may have been paid.

It is true that as regards the discretion to withhold licenses there is an appeal to the Governor in Council, but that everyone knows is simply an appeal to the Government Agent himself, as it is the invariable practice of the Governor to confirm the decision of subordinate officials, it being a rule of the service that an official cannot do wrong. Judging from the punitive and inquisitorial provisions of the Ordinance it has evidently been drawn up by the hand which framed the Gaming Ordinance when it was first published.

Your space will not admit of my putting forward all the objections which could be urged against the Ordinance, but I hope the unofficial members of the Legislative Council both native and European will raise their voices against the imposition of a tax which may swamp an industry which is the most hazardous that exists, and scrutinize provisions which place such enormous power in the hands of irresponsible officials.—I am, dear sir, yours truly,

C. S.

P. S.—It is probable that prescription will bar Government rights to precious minerals in many private lands.

THE CEYLON TEA PLANTATIONS COMPANY, LTD., IN THE KOTALGALOYA VALLEY.—Our largest Tea Company has just "stretched itself" by the addition of no less than four estates in Dimbula—Cameron's Land, Lochiel, and Rosita in the KotalgaloYA Valley, and Tangakelly. The first three have been purchased from Mr Hill, of Harrington, and the last from Sir William Gregory. According to the Directory, the extent of these estates is as follows:—

	Tea acres	Total acres
Cameron's Land.....	165	257
Lochiel.....	168	204
Rosita.....	nil	310
Tangakelly.....	323	348
Total.....	656	1,149

All the above are estates which ought to do well for the Company, Cameron's Land in particular being as fine and strong a sheet of tea as one could wish to see. Mr Hill keeps Harrington, where he will reside and have charge of the other estates—Lochiel, Cameron's Land, and Rosita—on behalf of the Company.—Local "Times."

THE RUBBER SUPPLY FROM BRAZIL.—A New York rubber importer, speaking of Brazil, said:—"Unless the ports are blockaded, and traffic on the coast interrupted, commerce will be little interfered with, and prices will not fall, as some predict. The only apprehension is in regard to the effect upon Brazilian finances. Brazil has lately enjoyed a boom, something like the Argentine Republic, and everything has become inflated. A considerable amount of money from Europe has been invested in securities and business interests there, and loans have been negotiated by the Government. Brazilian exchange has risen in the last two years from 20 to 28, which is above par. Should a financial crisis be precipitated by the trouble the effect may be serious. I don't think the Brazilian people are ready for a change to a Republican form of government just yet. There is a large class of poor, ignorant people who were recently released from slavery. The existing Government—or the late Government as it may now be styled—has been exceedingly liberal and progressive, and should have had the better classes with it."—*India-rubber Journal*.

COCOA, COFFEE, AND TEA EXHIBITS IN THE PARIS EXHIBITION.

The representation of cocoa manufacture at the Exhibition is very full and complete, our friends from Holland taking a decided lead numerically, as well as in regard to the area of space occupied. Chief among the Dutch exhibitors in this branch of commerce is the eminent firm of Messrs. C. J. Van Houten and Zoon, who have no less than five distinct exhibits illustrative of their cocoa and its mode of distribution to the public. In their principal building, a handsome annex constructed in the sixteenth century style of Dutch architecture, and of which we give an illustration, cups of the firm's cocoa are served to visitors by young girls dressed in national costumes as worn by the women of north and south Holland, Friesland, and Zealand. Crowds of visitors flock to this elegantly-fitted pavilion each day, and partake of Messrs. Van Houten's refreshing beverage. Elsewhere in the grounds forming part of the Netherlands section of the Palais des Industries Diverses, the firm's second exhibit is to be seen, consisting of a pretty chalet designed in the ancient Dutch style, its interior artistically furnished and ornamented with the engraved certificates received by Messrs. Von Houten at previous exhibitions, with glass cases holding medals awarded to them, and with orders conferred upon them in recognition of the excellence of their manufacture. A third exhibit of the firm will be found in the Palace of Food Products on the Quay d'Orsay, where among other goods in the Dutch section a pyramid of Van Houten's cocoa, enclosed in boxes and export cases, attracts much attention. The Javanese village near the Place des Invalides contains another of the firm's exhibits, tended by natives from Java, among whom and throughout the Dutch Indies generally Van Houten's cocoa is, we learn, very popular. The fifth exhibit of the firm is placed in the Colonial section of Holland, and comprises, appropriately enough, the model of a cocoa plantation, showing visitors how the cocoa is harvested, the case containing this model being flanked with cocoa-trees, thus fittingly completing a most interesting display. In the firm's establishment at Weesp five steam-engines are employed to dry very complicated machinery fitted up in the factory, which is illuminated by the electric light, land occupied by about 450 work-people. Despite its capacious proportions, it appears that this factory is not yet sufficiently extensive to meet the increasing demands upon its resources, and that a new structure on a much larger scale will soon become necessary. The accessories to the factory include a workshop where the boxes and cases used for packing the cocoa are made by the firm, some 40,000 tin boxes being turned out every day from this workshop; while there is also a printing-office attached to the factory. In addition to the establishment at Weesp, Messrs. Van Houten & Zoon have a special factory in Germany, situate at Dusseldorf, where they employ some sixty persons in packing and dispatching their cocoa to German customers only. Messrs. J. S. Fry & Sons, of Bristol and London, are the sole representatives of the English cocoa trade in the section devoted to Great Britain. They have a handsome stand decorated in black and gold, and containing samples of their pure concentrated cocoa, prepared by a new and special scientific process, through which extreme solubility is secured and the finest flavour developed. Messrs. Fry also show chocolate in great variety.

The display of tea at the Exhibition is by no means extensive. There is a handsome Indian pavilion in the grounds, certainly, but this building, which has been associated with the names of Indian tea growers, and erected at a cost of several thousands of pounds, comprises for the most part small shops, where Oriental wares are sold, the principal being that of Messrs. Liberty. We searched diligently for the exhibits of our Indian tea growers. The only trace of them we could find was in the most prominent part of the Pavilion, the centre, where the Great Tower-street Tea Company were carrying on an A B C kind of business. Considering that there was supposed to be in this spot

a display by our Indian tea growers, we expected to see exhibited something connected with the production of that article, instead of which we found the names of various tea districts and gardens simply made the appanages of the trade of an individual firm. The whole affair is undoubtedly a tribute to the commercial enterprise of Mr. Thomas Lough (Great Tower-street Tea Company) and Messrs. Liberty (Regent-street), as well as an evidence of the sleepiness of the Indian tea growers or of their Association.

The Compagnie Francaise, of Paris, show samples of tea put up in little fancy packet-shaped tins, each holding about 1 oz. or 1½ oz. On the labels covering the tins is the statement: "Imported by the Compagnie Francaise; 'souchong fin,' box of ten cups for 50c."

Russian tea, or tea as sold in Russia, about which everybody talks, is shown by Messrs. Perloff et Fils, of Moscow. We have sampled some of it as supplied in Paris, and we find it to be a fair representation of the medium grade of tea which is used in the Moscow district of Russia. No doubt the Parisians are pleased to pay the high price asked for this tea, on account of the novelty of the article; but in our opinion a very much higher class tea can be obtained at less money in Moscow or of Russian shippers in London.

With a view of giving our readers information as to what coffee in Paris actually is, we recently visited the coffee-roasting works of Monsieur Ernest Trébucien, Cours de Vincennes, Paris, the most noted manufacturer of the article. His celebrated "Café des Gourmets," consists of blended coffees, highly roasted and coarsely ground. After roasting, the berry is thinly coated with a sugar syrup, by which it is considered the aroma is preserved. Monsieur Trébucien has furnished us with samples of this coffee, which we find has the flavour so popular in Paris. It is a thick coffee, and more suitable for taking with cognac, according to the French fashion, than coffee of a slightly acid flavour, and not too highly roasted, which is preferred by many connoisseurs in this country. We are told that M. Trébucien does one-fortieth of the trade in France, which amounts annually to 68,000 tons; whereas the yearly consumption of coffee in the United Kingdom, according to the latest Board of Trade returns, is under 13,500 tons. Monsieur Trébucien's display at the Exhibition is a very interesting one, comprising samples of his "Café des Gourmets" packed in tins, which are retailed at 95 centimes per tin of 125 grammes, about equivalent to 3s. per lb.; roasted whole coffee of various growths, and condensed coffee and chocolate put up in card-board boxes, &c. His chocolate is excellent. The quotation we have given above is high, but it includes a heavy French duty of 7½d. per lb. If the public at home would pay 2s. a lb. for coffee, or a price something like it, instead of going for the low-priced mixture, we are sure that the trade here would equally supply a very fine article. Being a member of the Jury, M. Trébucien is *hors concours* as an exhibitor.—*Ceylon Advertiser*.

PROCEEDINGS OF THE AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

COTTON EXPERIMENTS.

In response to applications from the Society, seeds of local standard kinds of cotton were received for Mr. Cameron's experiments in Mysore, from the Director of the Agricultural Department Dewas State, the Cantonment Magistrate, Agra, and Mr. Wishart of Cawnpore, who wrote:—"Mr. J. C. Nicholls, C. S., Judge of Cawnpore, has sent to me your letter of the 17th instant, with a request that I will supply the cotton seed required by you, this I have much pleasure in doing, and have forwarded to your address under separate cover, two lots of 2½ lb. each marked A and B, the former called *Jamnagar*, and the latter *Daysee*. Various kinds of Cotton come into the market, these are mixed together, and thus form the standard qualities of classes which are shipped for Cawnpore."

MOMBASA MANGOES.

Colonel Pollock wrote as follows from Mombasa, East Africa:—

"I send you some Mango seeds of a fruit, which considering it is not grafted, is one of the most delicious of mangoes: and the trees bear twice if not three times a year, much the same as on the Niger about which we have before had some correspondence. If in return you could send us seed of various bamboos, Lichies and any other fruit trees, I am sure the Administrator-General of the Imperial British East African Company would be grateful. If you could send us a lb of fresh Assam Tea Seed by parcel post we should be obliged. The mails leave Bombay for this once a month." The Bamboo, Colonel Pollock adds, is unknown at Mombasa and he is anxious to introduce it.

Bamboo seed of two kinds, recently received from Mr. Gamble, were sent to Colonel Pollock, and other seeds will be sent hereafter. The 18 Mango seeds received appeared in good condition and were sown at once.

PACKING PLANT CUTTINGS.

Mr. J. Cleghorn gives the following notes on Mulberry cuttings sent to him by the Society. The cuttings were placed in a wooden box in alternate layers with sand, and the whole thoroughly wetted. Mr. Cleghorn says:—"The Mulberry cuttings were despatched from Calcutta on the 18th April, arrived at Balasore on the 20th April, remained in the Steamer Co.'s godown until the 20th May, arrived at my house on the morning of 23rd May, and were planted out the same evening. On opening the box, I found the cuttings had thrown out roots and buds; so instead of planting in the usual manner, I laid them on the surface of the bed and covered lightly with soil. The 35 days included in the above dates were the hottest and most trying of the year." Writing on the 1st July, Mr. Cleghorn says "out of about 200 Mulberry cuttings I have 139 struck with shoots 6 inches high. Some of the cuttings have sent out 4 and 5 shoots. I expect about 20 more to strike. The result is extremely good considering the history of the package." On the 24th of July the cuttings were again counted, and 159 plants from 6 to 24 inches were found. As the cuttings had been down two months they may be taken as thoroughly established, and should this method of packing answer equally well with other plants, cuttings may be sent to the most remote districts in India, to places where the cost of transporting them has rendered it difficult to send rooted plants packed in the ordinary manner.

SCALE ON TEA.

In reference to the Scale on his Tea plants, replying to an enquiry, Mr. R. Ballard, Palampur Kangra Valley, writes:—"I have carefully carried out your instructions in using the emulsion, and wherever applied it has killed the Scale insect. Since the heavy rains set in, we have had no fresh bushes attacked, and the Scale insect is in abeyance. I have got a powerful microscope but cannot obtain a live insect to examine. I believe after the rains, and with sunshine, the insect will again give trouble, but I have got, thanks to you, every appliance ready and will attack vigorously."

Messrs. Mitchell, Reid & Co. also kindly gave the following information:—"We have no definite information regarding the blight (Scale), or we should have communicated same to you. The manager advised us that it had been washed off by the unusually heavy rains of the season, but it has by no means been killed, and it seems to be making its appearance again. The following is extract of Mr. Bowman's letter of 12th instant:—"Kindly send me up another pump for the blight, I found the work slow, and two pumps are necessary. I found it checks the blight very well, but doubt if it kills all the young in the shells. As soon as I am certain, a report shall be sent to you."

STRAWSONIZER.

In connection with the subject of insect pests, the fact referred to in Messrs. Barry & Co's. letter, that Mr. Strawson is attempting to adapt his invention

for the distribution of insecticides, manure, seeds, &c. to the requirements of Tea Planters, is of great interest to all connected with the industry: indeed, a machine which could distribute an insecticide cheaply and effectively and be capable of dealing with 8 or 10 acres an hour, would be of use to Indigo planters against the caterpillars which do so much damage to Indigo crops; and also in wheat growing districts. An abbreviated description of the machine, taken from *The Sugar Cane* is given below.

Messrs. Barry & Co. write:—"We enclose extract from a letter from the Managing Proprietor of an Assam Garden, who is now in Europe, which explains itself. Our correspondent is in communication with other authorities on Tea pests and the means whereby they might be destroyed, and we shall feel extremely obliged if you would favor us with the information asked for." The following is the enclosure referred to:—"Might I ask you to do me the favor of communicating with Mr. Wood-Mason, the curator of the Natural History Museum, Calcutta, who, I believe, is the first entomologist in India, and ask him to give the scientific names of the most destructive Tea pests, especially those which cause what we call Mosquito blight, and also Green fly and Red spider? But the mosquito blight is most destructive, and it is about that insect, its scientific name, habits, &c., that I wish for information to give to Mr. Strawson the inventor of the "Strawsonizer," who is in consultation with Dr. Riley and other authorities as to the best chemical solutions, &c. to be used in his machine for the destruction of the various kinds of insect pests."

The following reply was sent to Messrs. Barry & Co.:—"I had the pleasure of forwarding copy of the extract enclosed in your favor of the 20th instant relating to tea pests to Mr. Wood-Mason and of asking him to favor us with a Memorandum giving the names of the more destructive tea pests, Mr. Wood-Mason refers us to his "Report on the tea mite and Tea bug of Assam, which he mentions can be had from Messrs. Thacker, Spink & Co. for eight annas. Mr. Strawson would probably be able to glean information regarding other pests, as well as those named, from the chapter on "Blight" in the *Tea Cyclopædia*, published at the office of the *Tea Gazette*, 1881. As Mr. Wood-Mason's report has no plate of the more active and destructive pests of the two it deals with—the tea bug, or "Mosquito" (*Helopeltis theivora*) I have the pleasure of sending you a copy of Mr. Peal's paper to which you refer, published in this Society's Journal, Vol. IV, N. S. I have also the pleasure of sending copies of this Society's Proceedings for January 1888, and for May and July 1889. In the first the result of a trial of an insecticide distributed in a liquid state through a suitable pump, is given. Mr. Jamieson, of the Second Fallothi Tea Co. reported that though the insecticide appeared, to some extent, to check the "Mosquitos" attacking the plants, the cost of the application, and its frequent renewal, was prohibitory. This may, to some extent, have been due to the construction of the distributing engine, which resembled the ordinary garden hand pump in appearance, being fixed to a receptacle to hold the wash, and mounted on small wheels; the machine would therefore be an awkward one on hilly gardens, or even to wheel over broken land and between tea bushes. In the two proceedings of the current year sent, reference is made to a new pest which has appeared in the Kangra Valley. This pest does not appear very formidable now, the means of destruction adopted having proved efficacious, as the enclosed extract from a letter received yesterday will show: as, however, allied species have been found to cause most serious damage to coffee, and in America to orange plantations, it may be that we have to congratulate ourselves for having found remedy at an early stage." Mr. Peal's paper referred to above was written in 1873 when the tea bug was just coming into prominence as a destructive pest, and the seven plates which illustrated it, show the insect in various stages, and the effect of its attack on the leaf.

COCONUT BEETLES AT THE STRAITS.

Mr. C. F. De Mornay, of Malakoff Estate, Province Wellesley, writes as follows to the *Pinang Gazette* :—

The proposed "Ordinance for the protection of Coconut trees from the ravages of certain Beetles" may seem to persons unacquainted with the cause of the great increase in the number of these insects quite unnecessary; but when they know how impossible it is for the owners of coconut plantations to prevent their property being destroyed by one of these beetles, they will, I think, acknowledge that the Government is acting wisely and justly in coming to their assistance. Though it may not be advisable for Government to protect or foster any particular branch of industry, it is only fair that it should step in to protect one threatened with destruction, through no fault or want of care on the part of those engaged in it, but by the neglect of certain duties for which other people are properly responsible. These duties are the destruction, removal, or rendering innocuous of rubbish, trade refuse, &c., produced in their business or on their premises. As regards the draft Ordinance published in the *Government Gazette*, I am of opinion that, in its present form, it would not have much effect in checking the ravages of the beetles, and that a more intimate knowledge of their habits is required before a suitable measure can be framed. The drastic remedy of cutting down all the coconut trees attacked by beetles would cause serious loss to the owners without any appreciable benefit. If not trespassing too far on your space, I propose making some observations on the habits of these insects, which, I hope, will prove useful in suggesting means for reducing their numbers.

The Rhinoceros beetle (described as *Oryctes Rhinoceros* in the schedule to the proposed Ordinance) is, I think, too well-known to need description here. It is by far the most numerous and destructive of these pests. Only the perfect beetle of this species attacks living coconut trees, the larvæ or grubs living only in decaying vegetable matter. I mention below some of the materials that seem to be the most attractive beds for breeding these beetles:—

1. Paddy straw.
2. Paddy husk.
3. Coir refuse, rubbish from dust bins, bark, tan, saw dust, &c.
4. Cattle manure and stable litter.
5. Dead trunks of coconut trees.

Certain other kinds of refuse are said to breed these insects, but of these I cannot speak from personal knowledge. It is remarkable that the stems of the tapioca plant and the *ampas* (refuse from the roots), when rotten, never breed these beetles. Whole coconut husks, when heaped until quite decayed, also prove unattractive. It is possible that by analysis Government might determine what it is that makes these substances unpalatable to the insects, and thus discover means of preventing their breeding in other refuse.

The beetle lays its eggs in some accumulation of moist and decaying vegetable matter, where the larva, a whitish grub, is duly hatched, and lives until it attains its full size, about $2\frac{1}{2}$ inches long, and as thick as a man's middle finger. It then becomes a chrysalis of a light-brown colour, the forepart of which resembles the perfect beetle, except that the head, horn, wings, and legs are enclosed in a kind of casing. It still inhabits the refuse heap until the time for it to take its flight as a perfect beetle. The beetle leaves the place it was bred in always at night, and flying in the direction of the prevailing night wind, reaches a coconut tree, alights on it, and proceeds to bore into a leaf near the butt; often boring through young unfolded leaves, which gives them the cut, ragged appearance so often seen after they unfold. The beetle sometimes passes the day in the hole it has bored, and, being unable to fly by day-light, is found by the coconut tree climbers, who extract it by means of a barbed needle. This plan answers well enough in keeping down the number of beetles on a plantation, if there are no large accumulations of rubbish or trade refuse, &c., in the neighbourhood; but when this is the case, or the plantation is situated near a village, it is impossible to cope with the insects in this manner, and the trees

rapidly sicken and die from repeated attacks. The only means I have found practicable, when these beetles become too numerous to be kept down by extracting them from the trees, is to search for and destroy the grubs in their breeding places, or to render these unsuitable for hatching and feeding them.

Paddy straw is a favorite breeding place when stocked in the usual manner, the grubs being found only in the layers nearest the ground, which are always damp and more or less decayed. I successfully prevented the grubs being bred in this by having the straw stocked on a platform of split bamboos (ribongs or saplings would answer equally well) sufficiently high to keep the ground underneath free from litter, and to allow for ventilation. Not a single beetle or grub ever bred in straw stacked in this manner, and it is a cheap and effectual plan of dealing with it. Indian cattle are chiefly fed on paddy straw, and their introduction here has caused the natives to purchase or collect it for that purpose. It is usually stacked near the cattle-sheds, and provides numerous large beds for breeding the beetles. Paddy straw is used largely at potteries, and is usually stacked in the same manner. On account of there being now a market for the paddy straw, the Malays often neglected to burn it off on their fields, as used to be customary, and the heaps left rotting there may also breed beetles. Paddy husk is another favourite breeding place, and should be burnt as produced, unless it is required for any purpose, when it should be stored in raised magazines. Near rice-pounding establishments in Province Wellesley, the coconut trees die in large numbers from the attacks of beetles. It is sometimes used at potteries. Coir refuse, rubbish from dust bins, tan, bark, &c., are mostly difficult, if not impossible, to burn, and should either be thinly spread over adjacent land, or, as I would suggest, emulsions of Jeyes' purifier, carbolic acid, kerosine, Paris green, or some other insecticide might be sprinkled over the heaps with the idea of preventing the grubs from breeding in them. Cattle manure has to be heaped for some time in order to render it suitable for manure, and is too valuable to destroy by burning in agricultural districts. The grubs are usually found a few inches from the surface of the heaps, so they are easily discovered and destroyed; but I think it might also be treated in the way suggested for dealing with coir refuse, &c. Large numbers of beetles are bred in the stable litter at the homes of Europeans and natives in Penang, which must greatly increase their numbers. The beetles have no particular breeding season, but breed all the year round.

Red Beetle, (?) named *Rhynchophorus Ferrugineus* in the draft Ordinance, is I think, probably a variety of *Calandra Palmarum*. I have never found any of these beetles of a uniform red or orange colour as mentioned in Dr. Simon's report on coconut beetles. This beetle itself does no harm to coconut trees. It is the larva or grub that damages them. It has been generally stated that the beetle searches for wounds in the coconut tree made by the coconut climbers with their knives, and deposits its eggs in them, but I think it more probable that it acts in a similar manner to other beetles of the same family, as, for instance, the corn and rice weevils, and itself punctures the hole where it deposits its eggs. It has been said that their rostrum is not sufficiently strong for it to do this, but in my opinion it is quite strong enough to punch a hole in the soft parts of the crown of the tree, which is probably much softer than a grain of corn or rice. The grubs are hatched in the pithy material, usually called the cabbage, through which the leaves sprout. They bore through this and the soft part of the tree in all directions, without, however, making any external wound. If not discovered, they eventually kill the tree by eating through the base of the leaf spike, probably through their favourite food, the cabbage, having become entirely consumed. When a grub living in a coconut tree arrives at the time it has to change into the pupa or chrysalis state, it bores through the wood of the stem to the outside, near the top of the tree, and, on the thickness of the wood, manufactures a most wonderfully constructed cocoon from the fibres of the wood. In this it lies torpid until the time for

it to emerge as a perfect beetle. This beetle, unlike the Rhinoceros beetle, flies freely by daylight. They are not very numerous here, and I have never known much damage to be done by them. On account of their habits, little can be done to decrease their number, but for the same reason, they are not likely to increase to any great extent.

It is not easy to know when a tree is attacked by these insects, as it shows no very clear sign of their ravages until the leaf spike falls, when the tree invariably dies. If the heads of the trees are frequently inspected by skilful beetle-searchers, many trees may be saved by cutting out the grubs, their presence being known by the searcher either finding a cocoon in the tree, or, more generally, by noticing slight wounds on the smooth skin (if I may call it so) of the leaf spike, which are unintentionally made by the grub in eating the soft pithy mass through which it pushes its way. Several grubs and beetles are sometimes cut out of one tree.

I may mention that, some years ago, the coconut plantation belonging to this estate was being rapidly destroyed by the ravages of the Rhinoceros beetle. Finding that increasing the number of beetle-searchers had no appreciable effect, I commenced searching for the grubs, and, at the beginning, with one coolie, used to destroy from 300 to 1,000 in a day. By destroying them and preventing them from breeding in the paddy straw, they decreased rapidly in number, the plantation became healthy again, and I found one beetle-searcher sufficient to keep the trees free of them. In my case I found it necessary only to search the refuse heaps to the eastward of the plantation, that being the general direction of the night breeze.—*Straits Times*.

KEW BULLETIN AND TROPICAL AGRICULTURE.

We have more than once called attention in former years to a very useful and very interesting collection of occasional notes and memoirs, on matters connected chiefly with economical botany, periodically published by the authorities of the Royal Gardens at Kew, under the title of the Bulletin of Miscellaneous Information." The Bulletin is issued monthly, in separate numbers, and at the close of the year the several numbers are collected together and published in a single volume, at moderate cost, by Her Majesty's Stationery Office. Among the voluminous publications which are issued annually from that Office, it would be difficult to find many which rival this unpretending Bulletin in varied interest and genuine economical importance. The Royal Gardens at Kew are, as it were, an Intelligence Department for Economic Botany and a central Botanical Exchange for the whole British Empire. A paper in the number of the Bulletin for May, 1889, gives a list of Botanical Departments and Establishments at home, in India, and in the Colonies, in correspondence with Kew. It occupies five pages, and its range extends from Darjeeling to Cape Town, from Ottawa to Sydney, from Jamaica to Fiji. Another paper, of some forty pages, in the July number, consists of a "Guide to the Botanical Literature of the British Empire." "The primary object of this compilation," says an introductory note, "is to supply useful information on the literature of the systematic, economic, and geographical botany of the Possessions, Dependencies, and Protectorates of the British Empire. Kew is often called upon to answer questions, on the shortest notice, concerning the vegetation of some remote part of the world, and the best books to consult on the subject. Such questions are not always easily answered, and they frequently entail a considerable expenditure of time; hence the idea of preparing a concise guide." Here we obtain a glimpse of the important and comprehensive func-

tions discharged by Kew in the commerce and economy of the Empire. England is the common market of the world, and the dominions of the Queen contain almost every climate to be found on the surface of the globe. Broadly speaking, it is hardly an exaggeration to say that the bulk of our trade, consists in the export of minerals and mineral products, and the import of vegetable staples. Hence the vital importance of a systematic survey and co-ordination of the botanical resources of the Empire at large. As regards the more common and familiar products of the vegetable kingdom, it is true, no doubt, that our merchants know where to find them, and that self-interest and competition will infallibly direct them to the cheapest market. But new products are perpetually finding their way into the market as staples, and the enterprise and ingenuity of Englishmen are constantly transferring old products from the parts of the world in which they are native to other parts where they can be cultivated to equal advantage. This process is largely aided by scientific inquiry and organized research, and Kew, with its affiliated establishments in all parts of the Empire, furnishes the machinery whereby scientific inquiry and organized research, are applied to this important department of the national economy.

A mere glance at the table of contents of the Bulletin for 1889 will show how admirably Kew fulfils its purpose in this respect. The Bulletin must not, of course, be regarded as a summary or survey of all the work done at Kew for the study of scientific botany. It is merely a series of notes, on subjects which have been brought to the notice of the Director and his assistants in the course of the ordinary work of the establishment, and have been adjudged by them as of sufficient general interest to warrant the publication of information concerning them. Accordingly, in one number we have a brief account of the various woods produced in Tasmania, with an estimate of their commercial value; in another, a catalogue of the fruits grown in Mysore, in continuation of similar information, published in previous numbers of the Bulletin, concerning other parts of the Empire. The interests of horticulture—no inconsiderable industry in the aggregate—are not neglected, for the February number consists exclusively of a list of such hardy herbaceous annual and perennial plants as have matured seeds under cultivation at Kew in 1888—such seeds being available for exchange with colonial, Indian, and foreign Botanic Gardens, as well as with regular correspondents of Kew; while the April number contains a similar list of new garden plants, described and published in 1888. But, for the most part, the interest of the Bulletin is, as it should be, rather economical than horticultural. In the first number we find a very interesting account of the coca plant, the source of the now well-known and popular local anæsthetic known as cocaine. It will surprise many of our readers, perhaps, to learn that this plant has been noticed and described by botanists and travellers for more than 300 years. It has long been largely used by the inhabitants of Peru and Bolivia as the source of a stimulant to the nervous system, in much the same way and for the same purpose as the Chinese use opium and the East Indians chew the betel, and for this purpose some 40,000,000 of pounds of the leaves are gathered annually, mainly from the plantations of Bolivia, the value of the crop being estimated at £2,000,000. Outside of South America the plant is used almost exclusively for the production of cocaine, an alkaloid which is extracted from the leaves. For this purpose its experimental cultivation has been undertaken in

Ceylon, in British Guiana, Jamaica, in St. Lucia, and in various parts of India, with results which are not unsatisfactory in themselves; but for commercial purposes South America holds the field, since it is able, as the Bulletin points out, without further extension of cultivation, to produce such enormous quantities of coca leaves, that the one-eightieth part would be sufficient to swamp the cocaine markets of the whole world." On another page we find a note concerning "Hardy Species of Eucalyptus." Whatever the medicinal and sanitary properties of this native of the antipodes may be, there can be no doubt that its naturalization in this country would be welcome for ornamental purposes. But the *eucalyptus globulus*, or ordinary blue gum tree, is only "sparingly hardy," in sheltered localities, in England. Kew, however, has lately received seeds of this species, collected from trees growing in Tasmania at high altitudes and exposed to severe frosts. Seeds of another variety, *eucalyptus coccifera*, have also been obtained from trees which were coated with icicles a foot long, and there seems, therefore, to be nothing very hazardous in the conjecture of the Bulletin, that plants raised from seed of such hardy forms would be likely to bear with impunity the rigours of an English winter. Another subject to which the Bulletin devotes considerable attention, though not more than it deserves, is the cultivation of a variety of useful fibres. The important subject of ramie or rhea was fully discussed in the Bulletin of last year, and this year we have a Report of great interest by Mr. Morris, the Assistant-Director of Kew, on the competitive trials, made at the Paris Exhibition, of a variety of machines for the decortication of the fibre. "Interest in ramie," says the Bulletin, "is becoming more and more general, and, judging by the correspondence addressed to this establishment, the subject is followed with keen interest at home as well as in India and the colonies." That it is followed with equal interest on the Continent is shown by the active competition of inventors in the production of machines of great ingenuity for dealing economically with the refractory, but very valuable, product. Another fibre of importance is that known as the Bahia piassava, which furnishes the strong, coarse, bristle-like stems which are used in scavengers' brushes and brooms, and for a variety of similar purposes, while the nut of the palm which produces it is well known as the coquilla nut, largely used in turnery. Familiar as this product is in both its forms in this country, no detailed account of the palm from which it comes, or of the processes of manufacture, has hitherto been published in an accessible form. The October number of the Bulletin now supplies this deficiency in the literature of economical botany.

Our extracts from the Bulletin have been made almost at random, and mainly with the purposes of exhibiting the range and variety of its contents. We might enlarge the selection almost indefinitely, if it were possible to condense the contents of the volume into the space at our command; but we must content ourselves with mentioning two other topics only. One of these is gambier, a substance of which few of our readers are likely to have heard, unless they are familiar with the details of the tanning trade. Yet gambier is an article, as we learn from the Bulletin, "which every tanner in the kingdom uses more or less; it used to cost £10 per ton and now costs £45." The rise in price is due to the increase of the demand in America, coupled with improvidence and want of intelligence in the cultivation of the plant from which the produce is obtained. This is the *uncaria gambier*, a shrubby climber, native of the Malay States, which

is largely cultivated at Singapore. The gambier, or *catechu pallidum* of the British pharmacopœia, is an astringent gum or paste, rich in tannin of a peculiar character, and is obtained by boiling the leaves of the plant. There seems to be no reason why the plant should not be freely cultivated in those tropical climates where such plants as cacao, vanilla, ginger and bananas are found to thrive, so that there is a very promising opening for British colonies which possess these climates, in the cultivation of a commodity which has risen in price from £10 to £45 a ton, mainly because the coolies at Singapore who are chiefly engaged in the cultivation, lack the enterprise or the intelligence to grow it in an economical fashion, "carrying on their operations on a system calculated to impoverish the soil, and producing an article of uncertain quality and often quite useless for commercial purposes." The last topic we can mention is that of the phylloxera, which appears several times in the Bulletin, mainly in connexion with the occurrence, actual or alleged, of that destructive pest in different parts of the world. The most important paper is that which describes the modes of combating the pest adopted in the Gironde. In 1881 the present Director of Kew attended an International Congress on the subject, held at Bordeaux, as the representative of the Governments of New South Wales, South Australia and Victoria. A summary of the conclusions he then arrived at is reproduced in the September number of the Bulletin. Broadly speaking, Mr. Thiselton Dyer holds that, although many palliatives and preventives may be, and have been, more or less successfully employed, "the use of American vines, at any rate as stocks, affords the only chance of maintaining vine cultivation in the future in Western Europe." This conclusion is based on the consideration "that the phylloxera and the American vines have grown up together in the New World, and, as the latter have not been exterminated, it follows that they have arrived at a mutual adjustment." It is true that the American grape itself does not appear to yield a flavour in the wine so delicate as that for which the produce of the Gironde has long been famous. But, by grafting French vines on American stocks, the flavour of the wines is preserved, while the ravages of the phylloxera are checked. These conclusions are further corroborated by a recent report of the British Consul at Bordeaux, who records the progressive increase of fresh plantations of vines, the new plantations consisting almost exclusively of American vines grafted with French plants of the best kind. Lovers of claret may, therefore, take heart of grace. The harsh American vine has come to the rescue of its delicate European sister and regenerated the vineyards of the Gironde, with the assured promise of renowned vintages and unimpaired flavours.—London Times.

THE WEIGHING OF THE TEA.

THE MADE LEAF.

(Sequel to "The Weighing in of the Tea," in the *Household Register*, Dec. 6th, 1889.)

The fresh young leaf that from the field is brought—
The issue it of constant, hopeful toil,
That calls forth plenty from the answering soil,—
Is weighed for test of faithful labour wrought.
Yet is the making with more labour fraught
Before the end is reached; and watchful skill
Must wither, roll, ferment, and fire; and ill
Betides, if care and knowledge are not sought:
Attention sees the manufacture grow
To merited success that cometh sure
Though waiting oft is long: the tea is weighed
The measure of the maker's gain to show:
Life's promise must be proved, and must endure
The stress of fashioning force—or, 't is not made.

Dikoya,

ALFRED NICHOLAS.

ACTION ABOUT TEA PLANTS.

IN THE DISTRICT COURT OF KANDY.—No. 2,640.

Neil M. Adam of Pendleton Estate, Wattegama, plaintiff, v. R. S. Pieris, Broomhill, Kollupitiya, Colombo, defendant.

This was a claim of recovery of R600, value of 200,000 tea plants, of which defendant took delivery of 150,000 and refused to take the balance. Defendant resisted the claim on the ground that the plants supplied were poor and unhealthy plants about two years old, unfit for planting and of inferior jät, that the defendant required the plants for planting on a large extent of land which he had just opened out, and that by reason of the plaintiff's breach of agreement the defendant lost a season for planting whereby he had sustained great loss and damage, to wit damage to the extent of R3,750.

At the trial, Mr. Beven appeared for the plaintiff and Mr. Sproule for the defendant. Mr. Adam, Mr. W. S. Marshall and Mr. Claud Hewat of Kanapediawatte, Gampola, were called in behalf of the plaintiff. The defendant, G. D. Jamieson of Mariawatte, Gampola, P. D. Almeida of Morali Oya estate, and Juan Fonseka of Moragala estate, Kurunegala were examined for the defence. Today (February 3rd) Mr. Lawrie gave the following

JUDGMENT :—

The plaintiff advertized in the local papers that he had for sale "Strong, healthy tea plants at R6 per 1,000 delivered at Gampola."

On the 30th April, the defendant wrote to the plaintiff:—"If you could let me have, say 100,000 tea plants, but you are advertizing at R6 per 1,000, I shall take on trial, and should the jät give me satisfaction, I shall be in a position to book your seed from next year as I require. I think you give delivery at from Gampola. Please state the age of the plants, kindly let me have a reply by return of post, as I am (sic) some tea plants Kelvin jät."

The plaintiff replied on 2nd May:—"I should like very much to do business with you and for that purpose I am quite willing to make considerable concessions, but I do not see how I can sell the plants I am advertizing for less than R4 per 1,000, deliverable at Gampola. The nursery I am advertizing is raised from Riverside seed, a jät highly recommended some time ago by the Tea Visiting Agent of the C. C. L. The nursery was planted by the late superintendent, and I purchased it from him when he was leaving for another estate towards the end of last year. My estimate of the good plants in the nursery is 204,000 but say 200,000, and I will sell you the whole for R700 if you will take them as they stand, or give you 100,000 delivered at Gampola at R4 per 1000. * * * The nursery plants are about 18 months old and are strong healthy plants. Most of them were stumped to one foot high after I purchased the nursery."

The defendant replied on 4th May:—"I shall gladly pay you R600 for 200,000 tea plants, although I do not require so many I shall take them at the above price. * * * I like stumps as they have to go a long way to the Kelani Valley, as delicate plants could not stand carriage. As soon as rain commences I shall send orders, or you will hear from my superintendent. You will have to send the plants to Ambepussa. I shall, of course, pay rail fare. I can get plants R4 from the Valley, but the plants are too small for June planting, so would require shading."

The plaintiff replied on 7th:—"Many thanks for yours of the 4th instant containing offer of R600 for the 200,000 tea plants delivered at Gampola. * * * I accept the offer and shall be obliged if you will give me timely notice when you require the plants, as I may need to send special coolies to the nursery to lift and carry the plants to Gampola. If I am not mistaken, the railway people insist on pre-payment of freight on plants. If so perhaps it would be convenient for you to send me a small cheque to cover probable cost of transport by rail."

The plaintiff sent off 150,000 plants in four different lots between the 12th and 22nd May. In his evidence at the trial he said of these:—"These were healthy plants, good healthy plants, about 18 months old, Riverside jät; the trees had all been stumped, all those above a foot high, quite fit to be planted, not a bit too old."

Mr. Claud Hewat said of the plants in the nursery: The plants were healthy and strong in May last. They were fit to be transplanted."

Mr. Marshall says he saw the plants in April when they were good and healthy in the nursery, in very fair order.

These 15,000 plants were received in Kelani Valley by Juan Fonseka, the defendant's superintendent. He says of them:—"They were not good plants, sickly, very old, jät bad, over two years old, the roots were very old, and the stumps thin, very bad plants." He put only a few in the ground to show the defendant. He did not think it right or worth while to plant the rest. Fonseka wrote his master, the defendant, who on 25th May wrote to the plaintiff:—"My superintendent has written to me to say that the tea plants are above two years old and are unfit for planting and that the jät is very inferior. If this be the case I am not at all prepared to take the plants as I never plant bad jät on my estates. Kindly give me some good jät and charge a little more if you like, and for the balance of money I shall take seed. If you can make this arrangement, I shall feel very much obliged."

Mr. Adam replied, but the letter has not been put in evidence.

On 29th May, Mr. Almeida went to Riverside estate in Nawalapitiya to inspect and report on the plants. He says:—"I examined the plants, they were very old, sickly and bad plants, not fit for planting. They were over three years old. I would not plant such plants in any land of mine;" and in cross-examination he added: "The jät was bad particularly, the plants too old and the roots were like yams."

On the 10th June, the defendant wrote to plaintiff: "I regret I cannot take your tea plants as they are not healthy good plants as you mentioned in your letters of the 2nd and 28th instant."

The plaintiff replied on 15th June: The plants in the nursery are, in every respect, the good strong healthy plants of Riverside jät they were described as being. The description was plain and distinctive, and you should have satisfied yourself as to their fitness for planting in your estate, in the Kelani Valley or elsewhere, before making the purchase. Now that purchase has been made and a portion delivered, I positive y decline to allow you to draw back. It would be neither reasonable nor businesslike. The remainder in the nursery awaits your orders for delivery."

On the 18th June, the defendant wrote that he would himself go and see the nursery, and, on 20th June, the plaintiff wrote telling him how the nursery would be most easily reached. It seems that the defendant did not then go, but, in September, he asked Mr. Jamieson of Mariawatte estate to inspect the plants in the nursery. Mr. Jamieson's report was:—"The plants in the nursery have evidently been topped a long time ago and seem to me about three years old. The roots of the plants are very long and large and are past the stage when planting could be done with safety. The plants themselves are stunted and hide-bound, not in a healthy condition, and great numbers of them are in blossom. It would be difficult to lift them out of the nursery, except at great expense, and they would require enormous holes to plant them in, such as no one would contemplate making in opening an estate. The age of the plants and their stunted appearance and the size of the roots make them unfit for planting in any clearing. * * * The jät is very poor, and no one, in his senses, would think of putting plants of such a class in a tea clearing. Looking at them in every way, I consider the plants in the nursery quite unfit for use in a clearing, and would condemn the nursery as quite worthless."

Mr. Jamieson's evidence at the trial was even more distinct,

Now, on this evidence, I cannot hold it proved that the plants supplied, or those which remained in the nursery, were fit for planting out; and I therefore hold that the plaintiff not having supplied and not being ready to supply the defendant with strong healthy tea plants fit for being planted in a new clearing, he is not entitled to the price which he now claims.

I dismiss the action with costs. The damages claimed by the defendant are remote, and I repel his claim in reconviction.
A. C. LAWRIE, District Judge.

MANURING HILLSIDES.—The bottom of a hill in the valley is undoubtedly richer in vegetable matter than the sides, unless the latter have been recently and heavily manured. But it is a fallacy to draw manure at any season on a side of a hill with the notion that it will wash down. We have tried that repeatedly, and the manure never fertilized much, if at all, below the line where it was drawn. Undoubtedly rains washed over the land and the manure on the soil below, but the valuable properties of the manure were deposited where it lay, while the deodorized water passed on below. It is doubtless to this necessity for water saturated with manure to sink that running streams and large bodies of water owe their power to cleanse themselves. The nitrates are heavier and sink to the bottom. Hence the mud from ponds and running streams becomes such valuable manure in many cases. It contains most of the fertilizing elements that the water above it has contained.—*Indian Agriculturist.*

INSECTS INJURIOUS TO VEGETATION.—Dr. O. V. Riley read a note at the British Association on "The importation and colonisation of Parasites and other natural enemies of insects injurious to Vegetation." Her said the encouragement of the natural checks to the increase of insects injurious to vegetation might be of a two-fold nature. It frequently happened that an indigenous species was found to have certain parasites in only a portion of the country which it inhabited. In such cases, where it was practicable to transport the parasites, a great deal of good might be accomplished. But this intentional distribution of the parasites from one part to another of its native country was by no means to be compared in importance with the introduction of such parasites, or enemies of injurious insects, from one country to another, in which the injurious species has obtained a foothold without the corresponding natural enemies which serve to keep it in check in its original home. The note proceeded to give illustrations of artificial introductions of the kind on a large scale, which had already been productive of great good.—*Gardeners' Chronicle.*

HOW TO CATCH FLIES.—A correspondent of the *Field* writing from Ashburton, New Zealand, says:—"On entering the bar of the W. A. O. D. Hotel at Eltham, 14 miles north of Melbourne, the visitor will notice what at first sight appear to be some large hams suspended from the roof; but on a closer inspection they are seen to be a number of compact boughs tied together, and finely woven over with spiders' webs of the purest whiteness. Mr. Purcell, the landlord, informed me that many years ago, while tormented with great hosts of flies, he hung up several of these neat bundles of boughs as resting-places for them. In a short time the spiders took possession, and have since continued to do good service in reducing the number of flies which swarm into the bar during the greater part of the year. There are from twenty to forty spiders in each group, the shaded entrance to each other's dwellings giving their work a very pleasing effect, but the older bundles are completely hidden in the shining mass of pure white silky webs. Perhaps the same experiment would afford pleasure to others who may think well to try it in other parts of the world."—*Aberdeen Free Press.*

COTTON AND COTTON-SEED OIL.—One of the large American insurance offices has issued to various persons in England a warning as to cotton bales impregnated with cotton-seed oil. They say:—"Since the introduction of cotton-seed oil, and its transmission in casks and barrels from one part of the country to another, a new danger has arisen to cotton in transportation, as cotton fibres saturated with this oil are very liable to spontaneous combustion. It may be that the more frequent fires in large cotton warehouses of the South and in cotton ships can be accounted for in this way. This year an instance of saturated cotton bales has been discovered in one of our principal mills. Two bales had been received, one of which was saturated to the extent of 256 lb., the other to the extent of 175 lb. A sample of the cotton has been examined at the Institute of Technology, and tested in our spontaneous combustion oven. It ignited at moderate heat in the way in which fibrous substances ignite when saturated with a drying or quickly oxidising oil. The oil pressed out from this small sample has been subjected to qualitative tests, which proved it to be cotton-seed oil. We therefore warn all members who represent cotton mills that it would be prudent to have their cotton carefully examined for oil, bale by bale, before putting it into the warehouse."—*O. Mail.*

The following pages include the contents of the *Magazine of the School of Agriculture* for February:—

THE NUTRITION OF PLANTS.

BY C. DRIEBERG, B.A., F.H.A.S.

That plants feed in some way and supply themselves with the nutriment necessary for growth is a fact known to everybody, but the manner in which food is assimilated and the form in which the various ingredients are taken into the plant—these facts are not so generally known. The food of plants may be either gases or liquids; they may never be solids. How then, some may ask, are solid particles of mineral matter found in plants? Not long ago a correspondent to a local paper described the phenomenon of a tree, in the centre of which a large deposit of 'sand' was found, and attempted to explain this uncommon occurrence by saying that the sand had probably been taken up with the water through the roots. Now this explanation must be set aside as totally incorrect. The solid mineral matter must have been taken into the plant (in combination) in a liquid form, and the deposition made after the liquid found its way into the interior of the plant. In this manner is it that the Diatoms contain silica, and the Charæ carbonate of lime. The silica most probably was taken up in the form of a solution of silicates, and by chemical reaction within the plant deposited as the oxide.

Thus the water with the mineral matter is got from the soil and taken up through the roots. The atmosphere is another source of plant food, which enters the plant in a gaseous form. The atmospheric food consists principally of carbonic acid gas, with smaller quantities of ammonia gas and water vapour. The mineral matter enters through the roots generally as salts, and it must be borne in mind that neither through the leaves as gases, nor through the roots as liquids, do plants take up any chemical elements. The element nitrogen is not taken up as such but as ammonia gas or nitrates or nitrites, through the leaves and roots.

The chemical elements which enter the plants as compounds may be afterwards broken up into their elements and re-arranged to build up new compounds to suit the requirements of the plant. The process of taking in the crude materials of plant food is called *assimilation*, that of re-arranging the chemical elements (which go to form this crude material) to build up organic compounds is called *elaboration*. And herein lies the great difference in the mode of nutrition of plants and animals, that whereas the plant has to elaborate organic food out of inorganic matter, the animal takes in its food as organic matter. (To this rule there are a few exceptions which we cannot wait to consider now.) The water with the mineral matter in solution is called the "crude sap," and the elaborated organic material which circulates through the plant bearing nutriment to every part just as the blood carries nutriment to every part of the human body, is called the "elaborated sap."

But how is it that the gases in the atmosphere and the mineral matter in solution, taken up from the soil, enter the plant? In the epidermis of the leaves are the stomata, spaces between two cells known as the "guard cells" which regulate the opening and shutting of the stomata. Through the stomatic apertures the gases in the atmosphere are taken up. The water and mineral matter, it has been stated, are taken up by means of the roots. The taking in of water by the roots depends on the process of diffusion or osmose. The cells forming the growing point or protomeristem of roots (and also of stems) are entirely filled with dense protoplasm. The cells lying behind the growing point contain less protoplasm and more water (cell-sap). Still further from the growing point, in the region of permanent tissue, the cells are filled principally with cell-sap, *i.e.*, water containing nutrient substances in solution, with little or no protoplasm. By the action of diffu

sion or osmose, the cells immediately behind the growing point deliver up part of their water to the younger cells of the growing point in front of them, and take water from the cells containing less protoplasm and more water, which in turn take water from the still older cells. And so this action of one cell containing much water, delivering up part of it to the next and younger cell containing less water, goes on till we come to the root-hair cells. These root-hair cells contain a thick sappy fluid saturated with dissolved nutrient substances, and so are enabled by the action of diffusion to take less saturated solutions from the soil. Now both the gaseous material and the liquid matter meet in the leaves—the crude sap travelling right through the plant from the roots: so that the leaf may be described as the laboratory of the plant, where the manufacturing goes on. Now let us enquire what chemical elements the plant requires in order to manufacture the organic matter to build up its tissues, in what compound forms the plant takes these elements, and lastly how, so far as we know, this manufacturing is carried on.

(To be continued.)

LIFE-HISTORIES OF INSECTS INJURIOUS TO VEGETATION IN CEYLON. IV.

BY ABA.

1. Order Coleoptera—Beetles.

1, *Calandra Oryzae*, Linn.; 2, larva; 3, pupa, magnified.

The *Coleoptera* or beetles form an exceedingly numerous and compact order. The beetles are mandibulate insects having four wings, the upper or first pair of which called the wing-cases or *elytra* are usually horny or leathery and not at all suited for flight. They form a "sheath" or covering for the large membranous hind wings which are folded beneath them when at rest. The inner margins of the wing cases touch and form a straight suture down the back when closed. The head is furnished with large eyes, jaws moving transversely, and with horns (antennæ) of a great variety of shapes.

A great many of the beetles are remarkable for their brilliant colours or singular shapes. A Ceylon specimen the "Ran Kuruminiya" of the Sinhalese is of a beautiful metallic green colour with yellow spots. The beetles have usually such a strong family likeness that they are seldom likely to be mistaken for insects of the other orders.

At present nearly 100,000 species of beetles are known to exist; these are mostly terrestrial but a few live in water, and the hinder legs of these are often flattened and oar-like in shape, and fringed with hairs.

Many of the beetles are very injurious to vegetation particularly in the larval stage as the [cockchafer, wire-worm beetle (*Toxica*, Sinh,) &c. Some prove eminently useful by preying upon caterpillars, plant lice, and other destructive insects. Others act the part of scavengers by removing carrion, dung, and other filth upon which they subsist. A few of the beetles (*Cantharidæ*) are used in medicine for blistering and other purposes.

The *larvæ* of the beetles are usually fleshy grubs with scaly heads furnished with jaws (the grubs found in dung heaps &c). They are usually provided with six legs, but are sometimes legless or apodous.

The *pupæ* are "necromorphous" or mummy-like. The head is bent forwards and the different organs of the future beetle enclosed in separate coverings are laid along beneath the breast and abdomen, with the pupa-skin closely enveloping the whole. The *pupæ* are inactive, whitish in colour and resemble the perfect insect in shape. Some of the beetles assume the pupa state in a cell of agglutinated earth or other matter, and the often fully-developed insect remains inactive for a considerable time before quitting its cell.

It is beyond the scope of this series of articles to enter more fully into the description of the *Coleoptera*; the reader is therefore referred to the works of Kirby and other entomologists for a fuller description of this and the other orders of insects.

I will now proceed to give the life-histories of the *Coleopterous* insects that are commonly injurious to vegetable productions, as I shall the other insects under the different orders. I shall begin with the rice weevil (*Calandra oryzae*), the gulla of the Sinhalese, an insect well known to my readers as occurring in all kinds of rice.

The description which follows is partly the result of the writer's own observation and partly gathered from "An Account of the Wheat and Rice Weevil in India" by Mr. E. C. Cotes of the Indian Museum, and other sources. But it is not to be considered that the account is at all complete; on the other hand there is much information wanting especially with regard to prevention and remedies, and to whether the attacks of the pest are confined only to stored grain as at present supposed or occurs in the field and elsewhere. It is worthy of note here that the weevil is not known to attack rice in the husk (paddy) when stored or otherwise.

Mr. Cotes thus notices the occurrence of two distinct species of the weevil:—"Stored grain in different parts of the world is liable to be attacked by two distinct species of weevil, viz., *Calandra (Sitophilus) granaria* and *Calandra (Sitophilus) oryzae*. These two species are so much like each other and have habits so nearly identical, that no study of the subject would be complete without taking both species into consideration. *C. granaria* is supposed to have been introduced

into Europe from the East (probably through Egypt), and now occurs throughout the whole of Europe and America. It is larger than *C. Oryza*, but superficially almost exactly like it; it is, however, without the eight coloured spots on the elytra (I have never noticed these spots in Ceylon specimens) * * * *. It is said to be entirely confined to granaries, attacking wheat, rye, and maize, and requires a considerable amount of heat for its development.

The weevil found in India and Ceylon in rice, wheat, Indian corn, &c., is the *Calandra oryza* of Linnæus.

The female insect makes a hole in grains with her jaws and lays one egg in each grain. "The egg which is very small (0.5 m. m) is translucent and elongate. It is deposited at the bottom of the hole, and the space above it is then filled in with particles of grain gnawed into fine powder."

The larva (fig 2) is soon hatched, and eats its way into the heart of the grain. It is a thick and fleshy grub not unlike those found in dung heaps, &c. except in size." When full grown it is only 1.5 m. m. to 3. m m. in length. The grub is apodous or legless, obtuse and white in colour; the head is chestnut coloured. The segment behind the head and the caudal extremity are furnished with a few small bristles."

"The larva transforms into a pupa (fig. 3) within the grain without making any perceptible opening."

The perfect insect (fig. 1.) is a small dark brown beetle as all my readers are aware. "The head is produced into a rostrum, slightly curved and marked with coarse longitudinal furrows, composed of somewhat irregularly disposed pits."

(To be continued.)

INDIGENOUS FOOD PRODUCTS—CULTIVATED AND WILD. IV.

By W. A. DE SILVA.

Guttiferæ.

7. *Garcinia cambogia*, Sin. (Garake) a tree with entire evergreen leaves having an acid taste. The stem exuding a yellowish gum resinous substance when wounded. This plant is dioecious, having staminate flowers in one tree and the pistillate on another, and is found growing throughout the Island. The parts of the fruit are used as a food material. The fruits when fully developed are about the size of an orange and are marked with distinct ridges prominently seen. It is of a red or light red colour when ripe, and sometimes we have varieties having a pale white-coloured fruit. The fruit may be divided into two principal parts: one, the rind or the pericarp which is of an acid character having a gummy resinous substance pervading through. The carpels found inside are generally five or more in number, of a whitish or pink colour and succulent. This part of the fruit is edible and is of a strong sour taste, having a little sugary matter. Though this part is edible and more favourable when compared with the pericarp; still it is of very little economic value.

The other part, the outer portion (pericarp) is collected when ripe, and after separating into parts from the furrows is dried in the sun and smoked so as to preserve it longer. This is commonly known as Goraka, and is used throughout the Island as a condiment in the preparation of curries, &c., and serves the purpose of tamarind in India to a more or less extent. Another use found for the dried and preserved kinds of the *Garcinia* is in the pickling of fish, in order to preserve them better. This is used in large quantities. It has the tendency of preserving the fish in a good state when used with salt for a longer period.

The stem of this tree produces a fairly good timber for various purposes. The bark and leaves are used medicinally, both internally and externally, for constipation and inflammations respectively among the native medical practitioners.

8. *C. Tomentosum*, Sin. Kina.—There are several varieties of kina, some of which yield a good timber used for cart building. The variety *C. Tomentosum* is a hardy tree growing in the dry regions of the Island. They generally grow on sandy tracts. The leaves are dark green and leathery, with prominent net veins. As a food product it is not of much value, except for the berries which when ripe have a good taste, and are gathered and used in localities where the trees are abundant. The fruits are round and little bigger than peas. They are pale green when young, but when ripe have a yellowish colour. The outer covering is very thin and husky, and the inner portion next to the seed is pulpy. The bark of this tree is used in medicine for dislocations and swellings.

TREATMENT OF CATTLE.

It is more than surprising that during the recent epidemic of cattle disease, attention was not called to the report of the Cattle Commissioners of 1869. The enquiry was evidently one carefully conducted, and by men well-qualified for the work they undertook. A large number of cases were carefully watched and treated, and many *postmortems* performed, before any opinions were expressed or suggestions put forward. A pamphlet by Mr. John Capper, who acted as Secretary to the Cattle Disease Commission, entitled "Cattle Treatment in Health and Disease," is well worthy of perusal by cattle owners, as being mainly a condensed reprint of the opinions and recommendations of the Cattle Disease Commission. The writer makes the opening statement that the predisposing cause of disease among cattle in Ceylon may be traced to poverty of condition, and great absence of care. The changes of weather during certain seasons of the year are so sudden and great as to render it impossible for man or beast to bear exposure with impunity; and special care during such seasons must not be neglected. The condition of cattle-pens since 1869 does not seem to have improved one whit, for it was only a month or two ago that the acting

Sanitary Officer in his last quarterly report described them in words almost identical with those of the Secretary of the Cattle-Disease Commission, while suggestions for the construction of Cattle-pens on sanitary principles with due regard to proper ventilation, drainage, and space were made to the same effect. It is recommended most advisedly, that during the heavy bursts of the monsoon cattle should be allowed to remain in their sheds day and night, and supplied with a sufficiency of cut and dried grass and other food. Mauritius grass dried and stored is recommended as an admirable adjunct to paddy straw for purposes of stall feeding, and its introduction to the rural districts of the country is strongly urged. Manioca is said to be admirably adapted, after boiling, for feeding store and working cattle. The rapid growth of fresh grasses after the first burst of monsoon rains succeeding a protracted drought is recognized as a very frequent source of sickness among cattle at certain seasons of the year. It should be partaken of in the first instance very sparingly, supplemented with other food, and if possible after being partially dried. A small quantity of paddy straw might be given with the grass. The various forms in which cattle-disease exists in Ceylon have been brought together in a list, with the Sinhalese and Tamil names by which they are known.

	Sinhalese name.	Tamil name.
Ordinary murrain with purging	Pachana lede	Vedippu
Ditto with constipation	Malabade lede	—
Throat disease ...	Uguru lede	Paravu
Mouth disease ...	Kata leda	Wai kanai
Hoof disease ...	Kura lede	Kal kanai
Distended stomach ...	Kummoda adappan	Uduwala
Staggers ...	Kallamari	—

The leading difference between the rinderpest of Europe and the murrain of Ceylon is the absence of eruptions on the skin. The Cattle Commissioners met with two cases in which the typical eruptions of rinderpest were present; and cases of this nature were reported in a letter from the Ratamahatmaya to the Government Agent of the North-Western Province. If the name "murrain" is to be preserved in Ceylon, it must be admitted that the rinderpest of Europe is modified in the nature of its attack under the influence of varying conditions in the tropics. The most marked similarity between the two seems to be the characteristic submucous hemorrhage and congestion of the 4th stomach.

At any rate the Commissioners consider that in murrain we have to deal with a malignant fever of a highly contagious character, and the first and most important duty would be that of thorough disinfection. Carbolic acid is recommended most strongly as the most convenient and effective agent, and one by no means expensive. For washing walls and posts one wineglassfull should be mixed with each pailfull of wash. For drinking purposes one spoonful may be

mixed with 6 gallons of water. The cattle themselves may advantageously be sprinkled over with carbolic acid a tablespoonfull to a bucket. Where it is difficult to obtain the acid the next best disinfectant is sulphur vapour, or the same in combination with burning tar. The sulphur however cannot be used when the cattle are in the pens. Tar vapour unless very much concentrated has not this objection. All three may be employed together without interfering chemically with one another. It is also important that segregation and strict quarantine should be observed. The greatest cleanliness must be maintained; all refuse and excreta being burnt. The smoke of large fires is to a great extent preventive of infection, and the use of wood ashes for the absorption of the injurious parts of all descriptions of filth should always be borne in mind, for its simplicity and effectiveness, and from the fact of the materials always being at hand. Even dry earth should not be despised as helping to keep sheds clean and sweet. Tar either when applied to the walls or posts, or when burnt, is principally effective on account of the carbolic acid contained in it. Lime, either dry or as white wash, acts locally as a purifier though being non-volatile, it does not rank highly as a disinfectant. Chlorine gas is a powerful disinfectant, though hardly so convenient as those mentioned above. The Commissioners emphatically state that their experience has failed to impress them with a belief in any known curative measures. They however recommend, with a view to give the attached animal every chance of escape, that every full-grown animal should have, immediately after separation, half a pound of common salt dissolved in water, or the salt in combination with an ounce of sulphur. For a younger animal a less quantity in proportion,—and tepid water should be plentifully supplied if possible mixed with carbolic acid. The strength should be kept up with rice congee. Hot fomentations are advised where difficulty in swallowing appears. Of course any drugs to allay fever or to act as a tonic can be given as thought fit. But what must be impressed upon cattle owners, is the necessity of disinfection, now that we have the authority of a body of men who have spent much time and trouble in looking into the question, that the only way of stemming the progress of the disease is by destroying the power of contagion. Cattle owners must give up their belief, at least in this case, in curative treatment and come to see that they have a subtle enemy that all the decoctions of their native doctors cannot expel when once in possession, but that can be frightened away—by cheap disinfectants. I have known the case of a poor grass-man, who paid R25 to a native doctor when his animal was in *extremis*, who no doubt would have refused R3 for purchasing disinfectants that might have saved the life of the beast. This gives us an insight into the mode of reasoning among our cattle owners, which must be first upset, before they can be expected to adopt the suggestions thrown out in the valuable pamphlet which I am noticing.

BEE CULTURE. II.

BY ABA.

The name Bee is given to a large number of insects of the order *Hymenoptera*. The female insect is usually furnished with a sting in place of the ovipositor, but a Ceylon specimen the "Kana veyiya" is stingless.

In the perfect state all bees either wholly or partly feed upon the sweet juices or honey of flowers, but the food in the larval state is supposed to be the pollen of flowers, often called bee-bread, or a mixture of it and honey.

The bee and some other insects play a very important part in the economy of nature. When they pass from flower to flower in search of honey, they become the means of bringing the pollen grains in contact with the stigma, and aiding in the fertilisation of flowers.

Bees are found in almost all parts of the world, but chiefly in the warmer parts of it. The bee is a mandibulate insect, *i.e.*, it is provided with mandibles or jaws so that its mouth is adapted for cutting and tearing. Some bees use their jaws for cutting out holes into the tubes of flowers which are so deep and narrow that they cannot otherwise reach the nectar at the bottom of the flower. If the reader were to pick up a fallen tamarind flower and examine it he will be able to see a small hole half way down the tube of the flower. This hole has been made by a bee who has been in search of honey. Certain parts of the mouth of the bee is elongated into a sort of proboscis to enable it to reach the nectar or honey at the bottom of flowers. The proboscis of the bee is not tubular and adapted for sucking like the similar organ found in the insects of the other great tribe, the *Haustellata*. But it is generally more or less hairy, so that the honey adheres to it when it is thrust inside a flower. Neither the mouth nor the proboscis is employed in the collecting of the pollen or bee-bread which the insect carries home to feed its young with. The feathered hairs with which the body of the bee is clothed serve for gathering the pollen which adheres to them.

"The sting of the bee is a very remarkable organ, it consists of two long darts, protected by a sheath. A venom bag is connected with it, and powerful muscles for its propulsion. The darts are each furnished with a number of barbs, which render it so difficult to withdraw them quickly, that bees often lose their lives by the injury which they sustain in the effort. The male bee is destitute of the sting."

(To be continued.)

FINE GRAINS OF CEYLON.

BY W. A. DE SILVA.

We have several varieties of fine grain cultivated in Ceylon. It is supposed that this was the general food of the aborigines. Rice was introduced to the

Island after its occupation by the Indian invaders who accompanied Wijeyo. The antiquity of this grain in India cannot be easily determined. Anyhow, we are assured on historical grounds, that its cultivation and use was quite prevalent in that country from times far remote.

We can safely say that the aborigines used only these fine grains as their food, which fact is more evident, because we see them used even up to the present day, by people inhabiting the wild districts of the Island.

The nutritive properties of these grains are questioned, and some go so far as to say that the vile disease Parangi is caused by the constant use of some of these grains.

Without going so far it might be said that they are not very seasonable food for persons to be used constantly. On the other hand if properly cooked and eaten with other food some are fairly good substitutes for rice. I have heard on good authority that kurakkan if used with curd is as healthy a food as rice, and sometimes more nutritious. Fine grain is grown very little where there is a sufficient supply of water for cultivating paddy, but in districts where seasons are uncertain and the rainfall is scanty they are grown to a larger extent, and it is wise on the part of the *goyias* to do so, as otherwise, they would run short of food and will be put into still harder straits than some of them are at present in.

In some districts of the Island a tithe is levied on these products, and this is done where they are extensively cultivated. In other localities no tithe is levied, but still we find a few patches of land in every village set apart for their cultivation. According to the data gathered for the Catalogue of the Colindies Exhibition in London, 1886, the tithe on fine grain harvested in the Island varies from 50,000 to 60,000 rupees, representing a total value of crops of R500,000 to R600,000. And if we take into account the rest grown in patches here and there and not paying any tax, we can safely add to the above amount another 400,000 to 500,000 rupees value of grain, coming to total of R1,000,000 worthy of fine grain.

This amount will appear to be too much for those who have not seen how far these fine grains form a great part of the food of the people. The growing and preparation of these grains require more attention as they form a great part of the food resources of the interior of the Island. It is believed that the nutritive qualities of these grains are much deteriorated by the way of preparing them.

The principal varieties of fine grain generally grown in Ceylon are kurrakkan (*Ellusine Coracana*), Tanahal (*Setaria Italica*), Amu. (*Paspalum Scrobiculatum*), Meneri (*Panicum Miliace*) &c. A description of the different varieties and their properties will be dealt with in another issue.

SPEECHES ON PRIZE DAY.

Mr. GREEN said that he felt he owed an apology to the ladies present; but he did not send out the in-

visitations himself. This was an Agricultural School, and he was afraid they would find the proceedings somewhat slow. Whenever ladies went to prize distributions, they were accustomed to see benches full of boys or girls, and tier upon tier occupied; but here there were only three and twenty students fighting their way and going forth to practise in their own fields or those of others what they had learned there. They could not show those present crops and waving corn, and they could not exhibit anything in the way of vegetation except, perhaps, the decorations which the students had put up. He apologised for all these. To his Excellency he offered no apology. He was always of opinion that prize-days on a small scale were a mistake, but H. E. came among them three years ago when they were only struggling into existence and gave them help and encouragement, and now towards the close of H. E.'s reign they wished for H. E.'s benediction (*laughter*)—he meant valediction. Having in Mr. Driberg a new Superintendent, they had started on a new scale. Mr. Driberg could teach the students a deal of Veterinary, and he was now searching into the cause of cattle disease, which was one of the greatest hindrances to agriculture. Turning to the work done, he must confess he was disappointed. His primary object in starting the School was to help small agriculturists, and not the big ones—small owners of little tracts of land who suffered from distress for want of food. That want of food he had seen, and he was satisfied that it was caused by the people not knowing what to do with what they had. They threw away 3 bushels of paddy in sowing when 10 seers would be enough; and this saving of seed paddy would keep a family in comparative comfort for a month or six weeks, and that in a time of famine and distress was a great thing! That was what he had said to himself—to help the small landholder; but he had failed; except in some Tamil districts, which alone had reaped the benefits he had intended to confer. True they had men like the President of Tihagoda; but, speaking generally, they were not so successful in the Sinhalese districts as in the Tamil. Talking of large cultivators, he was reminded that a challenge had been thrown down to them by a writer signing himself "A Tamil Cultivator," who admitted that they could obtain successful results with small tracts, but not with large and offered to place a large tract at their disposal. He (the speaker) broke through the usual rule and wrote to the newspapers accepting the challenge. The writer did not, as requested, sign his name, but said that they must take 100 acres, instead of 50 as we had offered to take, and went on to refer to a lot of extraneous matter. He now had three Inspectors in Batticaloa under Mr. Elliott, who were engaged on a tract of 130 acres, and he expected them to shew that the results they had obtained on small tracts could be obtained on large areas as well. The report had touched on all the leading features of the work done, and he had nothing to add except that it gave him great pleasure to announce that Mr. Muttiah

had offered a prize of R25 for Geology, Mr. de Soysa a prize for Practical Chemistry, and Mr. Grenier a prize for Field Surveying which were all before His Excellency. (*Applause.*)

The prizes were then distributed by H. E., the recipients being loudly applauded, especially Guna-wardene among the Seniors and Kodipilly among the Juniors.

H. E. the GOVERNOR said that when Mr. Green asked him three years ago to be present at the first distribution of prizes, he said, he remembered, while giving away the prizes, that the young men who were leaving the School were not only going out into the world on their own account, but that in a manner they represented the School in which they had been educated, and that the School too might be said to be going out into the world to seek its fortune with uncertain fate. They then wished all prosperity to the School as well as to the individual students, though uncertain of their destiny. They now met again, and he thought they might say that the result of the venture had been a successful one. So far as he had heard, they had every reason to be satisfied with the conduct and good effects wrought by those who had gone out as Teachers and who were paid by Government and other parties. He might, perhaps, particularly mention Messrs. Perera and Silva, one of whom had done good service in the way of agricultural instruction, and not only that, but had shewn personal courage and devotion, during a recent outbreak of cholera in his neighbourhood. Mr. de Silva had also gained the prize offered for public competition for the best Essay on Cotton Cultivation, and now he is a Master of the School, in which he had been a worthy and distinguished pupil. That was very encouraging. H. E. ventured, three years ago, to point out certain rocks ahead—certain dangers which would have to be avoided, and he thought they might conclude from the success attained, that those rocks had been avoided and that the Agricultural Instructors had been able to convey instruction to those among whom they had been placed in a proper manner—that is without seeming, to be dictatorial, nor with any assumption of authority—and at the same time without any remissness of duty. They must look upon the School as a success, and he did not know that there was any great disadvantage that the benefits it confers should be slow and gradual, instead of being a sweeping and instantaneous revolution. He perfectly agreed with Mr. Green as to the benefits that might be apprehended from the increased improvements, and quite agreed with him as to the extent of the improvements that were required, and that they should extend them. But he thought that it was quite natural, and therefore necessary, that they should not be able to effect all that at once. The knowledge of improved methods and the results would filter down from the higher to the lower ranks of Native society, and they might depend upon it that, conservative though the Native

character might be, when once the benefits were apparent, the improved methods would be adopted. They had, therefore, every reason to be satisfied with the results, and every reason to hope as to the benefits; and notwithstanding the deprecatory wish of the Director of Public Instruction (*laughter*), he thought there was every reason to wish blessings on the school. He, therefore, wished those who were leaving the school prosperity and hoped that their career would be a useful one as well. (*Applause.*)

The Hon. Mr. MITCHELL said he thought he might be understood to express the feeling of all present that they had listened with great pleasure to the account that Mr. Drieberg had read to them of the working of the school in the past year. He thought they had every reason to be proud of the results. The Agricultural School, he believed, was commenced a short time before His Excellency came to the Island, and he was sure that the Director of Public Instruction felt that he had had very great assistance and sympathy and help and encouragement from H. E. With regard to the good the school was doing, nobody could be blind to that. Lads came from the country and studied agriculture there and went back to their villages or other agricultural schools; and no one could be blind to the fact that very important results must follow from that in the course of time. He felt beholden to Mr. Drieberg and those assisting him, especially Mr. Silva, because they had taken a very great interest in a matter that he was himself very much interested in—Cotton cultivation. They had been endeavouring to extend the cultivation of cotton, and he was sure that with their assistance it would be developed. In an institution like that, a study of English was, necessarily, involved, and they had seen that the study of it was carried on with very good practical effect. At the same time he deprecated—he would beg H. E.'s pardon for what might be thought his heterodox opinions—the study of English to such an extent as it was carried on now. (*Hear, hear, from Mr. Green.*) Of course, in an institution like that the study of English was necessary, as the text books were in English, but he thought they were affording means of acquiring that language to an extent that in its results would be appalling (*Hear, hear.*) He had received a number of applications for employment in the Cotton Mills from lots of young men who pointed out that they had passed examinations in English Literature, but they all wanted service as clerks. He believed there were numbers of young men who annually sought employment as clerks under Government and Merchants and he confessed he did not know what was to be done with them. He thought that English education was so readily and cheaply afforded, that it should be restricted. What he wished to substitute very largely was industrial and technical education, and he would ask those who agreed with him to join in a crusade of that nature, because he thought the time was come when it was necessary that such a course

should be taken. He remembered that in times gone by there was an industrial school in that very building, and the Superintendent taught the boys carpentry and such like trades. But on the Superintendent's retirement, this was discontinued, he did not know for what reason, and the school was abolished. That was a great mistake; but he trusted that before long a school of a similar nature would be started, and when started that it would receive a large amount of support. He would go the length of saying that they should diminish English education by its being taught only in the schools now in existence, and that they should make a technical and industrial education conditional for the receipt of Government grants. He could not say that he had any cut and dry scheme in regard to all this; but he threw out his ideas that H. E. might think over them. As regards this school, and its work, he thought that the boys who now came to it came and prosecuted their studies with more encouragement than those who had gone before them. He thought that the conditions under which agriculture was now carried on were improved, and that the tax on grain, it was possible, would be modified. He trusted that year by year there would be an increase in the number of pupils, and that they would continue to do as much credit to the institution as those who had preceded them. (*Applause.*)

OCCASIONAL NOTES.

HELLRIEGEL'S THEORY.—The theory known by this name would seem likely to have a new one. At the annual dinner of the Agricultural Discussion Society in connection with the course at the Edinburgh University last month, Mr. Hunter, Analytical Chemist, Minto House, said that some of those present had already heard much of the great discoveries attributed to Hellriegel in connection with the question whether leguminous plants had the means of procuring nitrogen from the atmosphere, for the building up of their tissues, and the storing of it in the soil. But he could tell them that years and years before Hellriegel was heard of, their own Botanical teacher, Mr. McAlpine had not only demonstrated the presence and the powers of these micro-organisms in the wart-like tubercles on the leguminous plants, but had also taught in his class the facts which were now regarded as the discoveries of Hellriegel. Mr. McAlpine who was present, remarked that he could corroborate Mr. Hunter's remarks with regard to the functions of the tubercles on the roots of leguminous plants. Some of them were well aware that many years ago he lectured on this matter, and pointed out the great importance that this source of nitrogen would prove to the Agriculture of the future. Mr. Archibald McAlpine, B. Sc. (London), is Botanical lecturer at Minto House—his lectures, largely attended, being recognised by the University. Personally a very retiring man, he is well known as one of the ablest teachers, and a Botanist given to much original research.

BOMBAY will soon boast of an Agricultural Farming Company to be formed upon the same principle as similar institutions of the kind in Europe which have been so successfully worked. The management will be entirely by Europeans, and the Agriculturist will live on the spot and personally superintend the Farm. The chief object of the company is said to be to acquire lands at Loni where it is intended to cultivate and farm vegetables, fruit, sugarcane, cereals, &c., to be sold in the Bombay markets, and also to deal in cattle, poultry, eggs, milk, butter, &c. The project is spoken of as one which will supply a long felt want.

GENERAL ITEMS.

The banana, or plantain tree, is said to yield for the same extent of ground a larger supply of food for man than any other known vegetable. According to Humboldt, the same space of 1,000 square yards which will yield only 462 lb. of potatoes, or 38 lb. of wheat, will produce in a suitable climate 4,000 lb. of bananas, and in a shorter period of time. The fruit of an ordinary banana tree averages about 35 or 40 lb. in a single season, but occasionally about 70 or 80 lb. of bananas are taken from one tree. The banana fruit when ripe consists of about 74 per cent of water, 20 per cent of sugar, 2 per cent of gluten or flesh-forming substances, and the remaining 4 per cent of mineral matter, woody fibre, and one or two other substances of less significance.

Says the *Indian Agriculturist*:—Agriculture is still in a very deplorable condition in many parts of India. The Indian peasant being unfortunately compelled by necessity to use the droppings of cattle as fuel, and prohibited by religious scruples from utilizing bone for the purpose of manure, is thus deprived of its only available sources of fertilization. The natural result is that the soil's productive power has been seriously impaired. Goat and Sheep breeding is suggested by the *Indian Agriculturist* as a remedy, because of their rich manure.

Professor McCracken of the Royal Agricultural College, Cirencester, having accepted an agency under Lord Crewe, has resigned his lectureship at the College.

Prof. McNab, M.D., Professor of Botany in the Royal College of Science, Ireland, died suddenly in Dublin last month. He was formerly Professor of Natural History at Cirencester, and is the author of several works on Botany, some of which have become standard text books.

Mr. Thomas Jamieson, F.I.C., Fordyce lecturer on agriculture in the University of Aberdeen, has been created a Chevalier of the Legion of Honour by the French Government in consideration of meritorious work in connection with agricultural research.

SCHOOL NEWS.

School reopened on the 15th January. Nine new students have been admitted to fill the places of those who passed out and left at the end of the last session.

Mr. J. S. de Saram has been gazetted acting Police Magistrate of Galle, and Mr. P. S. Rodrigo continues to ably fill his place in the School.

The following is the list of prizemen to whom H. E. the Governor distributed prizes at the end of last session:—

SENIORS.—Agriculture, T. W. Gunawardene; Practical Agriculture, T. W. Gunawardana; Chemistry, T. W. Gunawardane; Botany, T. Guaratne; Veterinary Science, V. Kumaravelu; English, T. Gunaratne;

Mathematics, T. W. Gunawardne; History and Geography, T. Gunaratne.

SPECIAL PRIZES, SENIORS AND JUNIORS.—Geology, Mr. Muttiah's prize (R25), J. Kodippily; Field Surveying, Mr. Gremier's Prize, T. W. Gunawardene. Prize by Mr. de Soysa for Agricultural Chemistry, T. W. Gunawardene.

JUNIORS.—Agriculture, J. A. Kodippily; Chemistry, H. D. A. Gunasekera and J. Kodippily; Botany, H. D. A. Gunasekere; English, J. Kodippily; Mathematics, J. Kodippily; History and Geography, J. Kodippily; Entomology, J. Kodippily; Geology, A. Drieberg.

NOTES FROM EXPERIMENTAL STATIONS.

MAVADI MUNMARI, 16th Dec. 1889.

My experimental station is situated in Manmunai Pattu, South-West, about 15 miles from Puliyantivu. The adjacent village consists of little over a dozen native dwelling-houses, but the extent of paddy land this little village includes amounts to more or less a thousand acres. The soil is of a sandy nature, and the crop most largely cultivated (as indicated by the name of the village) is "Munmari."

"Kálavellámai" can only be raised on a very few low lands where there is a sufficient supply of water; for as there are unfortunately no large tanks in this part of the country, capable of irrigating the fields, "Kálavellámai" is little raised.

We have a small tank here wholly dependent on rain, and as all the fields are sown with six months' paddy called Vellaikaruppon, Kallurndai and Perm Vennaiyan, any water stored in the tank is used, and is only sufficient for the growing crop during the months of January, February and March. Cereals cultivation also is carried on by the villagers during the months of October and November.

I have taken up for experimental cultivation about 30 acres, 26 acres of which are reserved for paddy and the rest set apart for cotton, dholl, &c. Cotton seed is now being planted, while the dholl is going through the nursery.

Owing to the unusual drought which prevailed during the last four or five months the paddy plants were stunted to some extent, but since the recent rains they have made a fresh start and appear much healthier, giving promise of a better yield than the crops of adjacent lands. During a late visit the Government Agent expressed his satisfaction at the result of the work at this station, and pointed out to the villagers the superior results of improved methods of cultivation. The fact that cultivators are appreciating the work done by the improved plough is evidenced by their requesting a loan of these ploughs for use on their own lands. This has been granted by the G. A. for once with the injunction that after having proved the thoroughness of their work for themselves, they should purchase implements for their own use.

B. M. CHINTVASAGAM,
Agricultural Instructor.

KULIAPITIYA, 6th Dec, 1889.

I completed ploughing my field with the improved plough on the 30th September for the mahā seasons and cross-ploughed with the native implement after an interval of six weeks. It has since been sown with Murunga wee, a paddy of three months' duration. The field is infertile sandy land irrigated by a small tank about $\frac{1}{2}$ of an acre in size. The tank being a small one, and as I was pressed for time after my arrival, I was only able to prepare about 1.1-5 of an acre of paddy land.

I have laid down 8 plots with onions which are thriving well.

Three varieties of Tomato were planted in September, and though a few of the plants were destroyed by bugs which bored into the main stem, the crop, which is ready for plucking is a promising one. I am at present engaged in felling three acres of jungle land to be reserved for cotton, and another half acre of forest close to the school for arrowroot.

The weather continues dry.

LAWRENCE PERERA,
Agricultural Instructor,

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. IX.]

COLOMBO, MARCH 1ST, 1890.

[No. 9.

CITRONELLA GRASS AS A MANURE.

I suppose we may say of Ceylon that of two oils of very different quality (the second being essential oil), viz. coconut and citronella, this colony exports much larger quantities than any

other colony or country in the world.* The first is used in the manufacture of soap in Continental Europe; the second mainly, we believe, for the scenting of fine soaps. It is useful otherwise, as an antidote to fungus in book and insect cases, as a useful application in rheumatism and so forth. We greatly regret to see it stated that some exporters of this fine oil adulterate it with kerosene. Mr. Cochran has been testing the residuum after distillation for manurial properties, and has kindly submitted the results for publication, thus:—

"Citronella grass, after the oil has been extracted from it by distillation, is used, both as a feeding material for cattle, and also, after it has been allowed time to decay, as a manure. It might be interesting to analyse the steamed grass as a feeding material, as I understand that, although cattle refuse to eat the grass in its natural state, even calves will eat it, after it has been mollified by the thorough steaming or boiling it gets in the process of oil extraction. It might also be interesting to analyse the steamed grass as a paper-maker's material, as, should it ever become a marketable commodity on account of its cellulose, the steaming process might be regarded as a step in the preparation. Meanwhile, I am able to give you an analysis as a manure of the steamed and decayed grass.

Moisture expelled at 212° f.	per cent.
Dry matter	82.65
	17.32
	100.00

The dry matter had the following composition:—

* Organic matter	per cent.
Ash consisting of	84.09
Silica	12.39
Oxide of Iron and alumina	00.97
** Phosphoric acid	00.30
Lime	00.61
Potash	00.09
Other constituents	00.74
	15.01
	100.00
* Containing Nitrogen	2.24
Equal to Ammonia	2.71
** Equal to tribasic phosphate of lime	0.65

It is evident that the manurial value of this substance is small. The nitrogen is the chief element of value present; of which the dry matter contains somewhat less than three-fourths of the amount in coconut poonac; whereas the manure in its wet state contains only about two-thirds as much nitrogen as farm yard manure. Of the mineral ingredients by far the most abundant is silica, which constitutes 82 per cent of the ash, or 12.39 per cent of the dry matter. It is possible that as a manure for sugarcane this silica may have a distinct value, as being, no doubt, more easily assimilated than the sand of the soil. The silica would be a drawback to the grass as a source of cellulose, as it would necessitate a greater expenditure of the caustic alkali to dissolve it out; but, on the other hand, analysis might show that the steamed grass contained a correspondingly lower amount of pectous substances than other grasses used by paper-makers, and, in consequence, less caustic alkali would be required to dissolve out the same. The ash contained an appreciable amount of lime and phosphoric acid, but a mere trace of potash.

M. COCHRAN.

CEYLON UPCOUNTRY PLANTING REPORT:

A SIGN OF THE TIMES: THE MOORMAN AND CINCHONA
—“TEA CULTURE AND PREPARATION IN CEYLON”
—COOLIES AND KANGANIES—THE LATE DRY WEATHER.
Feb. 4th.

Is it a sign of the times that the Moorman is out inquiring about cinchona? We all believe that there will be a rise in price by-and-by, but how that unit sticks! There is the information from London by last mail that the consumption of quinine is very great everywhere owing to the “influenza epidemic,” and that there have been large sales of quinine: while on this side we show rapidly diminishing exports; hear of the ravages of canker; and know that there is nothing being planted here to take the place of the dying trees. Yet in the face of all this you find the price of bark quoted locally from 7 to 11 cents, which has been a steady rate for goodness knows how long. Of course, there is as I say the Moorman beginning to inquire, but that does not amount to much yet: all that he does

* The exports in 1888-89 were:—Coconut oil, cwt. 327,430; citronella, 10,686,982 oz. The manurial value of the lemon-scented grass, so largely cultivated near Matara, is doubtless greatly increased after having passed as food through animals.

is to ask your price, and when you mention it he covers his mouth with his hand, anxious evidently to suppress his emotional nature. When he has gained command of his feelings, he then asks how many pounds you have for sale: chews a bit of the sample, as does his chum, and then the two look at each other in a most exasperating way:—"The bark has no bitterness in it" is what they declare, after this rude chewing analysis, but you get a bid. It is low enough to allow of an advance of a cent or two more, out of pure friendship for you, but not finding their kindly effort appreciated they move off. How does it pay these fellows to waste their time as well as ours? You find them walking miles, wasting hours, and never getting "a bit foralder;" but they may be like the swallows which herald the coming summer, and may encourage us to hope that "the winter of our discontent" is drawing to a close, and that we are on the eve of better prices for cinchona bark.

The latest issue from the *Observer* Press, "Tea Culture and Preparation in Ceylon," is as usual practical. There is squeezed into the 100 pages or so a vast amount of varied and useful information which represents the experience of scores of painstaking planters. I fancy it is only among Ceylon men that the production of such a Compilation would be possible: India with its longer experience of tea could show nothing like it. From the tea planters of the neighbouring continent we can get the elaborate essay of the single man, which is very valuable in its way; but this is altogether different, for it represents the wisdom of the many drawn out by the wit of one. It is a useful little Book, and the experienced teaplanner may refer to it at times with considerable benefit.

Coolies are beginning to arrive from the Coast, which is much too early for most men, with all the dry months ahead. It is the drought I hear that is driving them over. Recruiting should be an easy matter this season, and the returns of immigrants should be large; so what with Tamil labour and the local Sinhalese even the districts which as a rule find a difficulty in keeping up a sufficient force may fare well. Kanganies with "tundus" are as plentiful as crows, and the deeper the mine of debt into which he and his gang are plunged, the higher are his demands.

We were all beginning to wonder what was to be done with the labour force during the late dry weather, until the welcome rain came, which has been invaluable. It has soaked the soil in grand style, and we look for good flushes in due time.

PEPPERCORN.

GEMMING AND MINING ORDINANCE.

We had no time yesterday to refer to the remarks of the Attorney-General in introducing this bill. We were struck not so much by what his speech contained as by what it omitted, including all reference to the past policy of the British Government for over 90 years in Ceylon. Why revive at this particular juncture a claim which has lain dormant all these years although, notoriously, native gemmers have been constantly at work finding and appropriating precious stones which in the aggregate must have represented an enormous value? Again, it seems curious that while natives were allowed to dig and sink shafts and pits after a most dangerous fashion—in the case of plumbago, there are pits said to be 200 to 300 feet deep,—as soon as European enterprise is announced, the Government as "C. S." points out, must needs take steps to "guard the safety of persons employed in mining"! In respect of ancient royal rights to gems, we fear our correspondent is

scarcely correct; at least our reading, and the several authorities within reach—some quoted recently in the *Literary Register*—point the other way. But on another very important point started by our correspondent, we call on the unofficial members to take action so soon as the Legislature assembles again. It is stated that there is in existence an elaborate Report by one of Mr. Grenier's predecessors upon which the Ceylon Government in 1881 based the "Gem and Gold Mining Rules" which were then promulgated and which have operated ever since. We quote from our "Handbook," the more important of these, and we trust the unofficial members will endeavour to show that both good policy and good faith should lead to the maintenance of the Rules of 1881:—

General Rules.

The Government will claim no royalty on or share of the gems or gold found upon land in respect of which a license has been taken out, and is in force under these rules, but such land will be liable to any taxation which may hereafter be found necessary to provide, at the expense of the grantees, the cost of such special police communication, water supply, sanitation, or other similar administrative arrangements as may, in the opinion of Government, be dictated in the interests of the local community immediately or directly affected by the results of the grantee's operations.

Prospecting Licenses.

Prospecting licenses will be issued only for *Crown Waste Lands*.

No prospecting licenses whatsoever will be issued to dig for *gems*.

Prospecting licenses will be issued to dig for *gold* on payment of R10 and on the following conditions:—

The area on which the license is to extend shall not exceed half-a-square mile.

The license shall be in force for six months.

The grantee to have the exclusive right of prospecting within that area for that period and to have the option, at the expiration thereof, of applying for a regular lease of not more than 50 acres within the said area on the terms hereinafter described.

Gemming Lands alienated by the Crown.

The proprietors of lands on which the rights of the crown to gems have been reserved may obtain a license to dig for and appropriate such gems on the payment of R10, which license will be in force for one year, and may be renewed annually on the like payment.

THE CEYLON SPINNING AND WEAVING COMPANY (LIMITED).

Report of the Directors for the year ending 31st December 1889. To be presented at the general meeting to be held at 3 p. m., on Thursday, the 13th February 1890.

The Balance Sheet to 31st Dec. 1889 is now submitted to the Shareholders, and from it they will see what the position of the Company was on that date. Thus far, the work that has been carried on has been wholly in constructing the buildings and erecting the machinery, and it is obviously inexpedient to prepare a Profit and Loss Account at this time, seeing that the actual working of the mill is only about to commence. A good deal of unlooked-for delay has been experienced in the arrival of machinery chiefly owing to the delay of manufacturers, and the London Dock Strike detaining vessels, but on the whole it has not been greater than that usually attending such undertakings, and when it is considered that it is less than a year since the foundations of the buildings were laid, it cannot be said that much time has been lost. A "preparation," or complete section of the Spinning Machinery, is now running, and the whole will be gradually brought into work as quickly as possible. The services of a qualified weaving master have been secured, and a

the greater part of the looms have been erected, the Weaving department will be brought into operation very soon after that of the Spinning. A number of skilled hands have been procured from India, who will be able to train the local labour, of which there is every prospect of an unlimited supply. Arrangements have been made for supplies of Cotton from India to the extent that may be required to supplement those obtained in the Island, which it is hoped will now gradually increase. The Directors regard the prospects of the Company as very promising, and with good and careful management, the results ought to be as successful financially, as they have been in other respects. The retiring Directors are Messrs. R. L. M. Brown and W. Anderson, and they are eligible for re-election.

BALANCE SHEET OF THE CEYLON SPINNING AND WEAVING COMPANY, LIMITED.

Made up to 31st December 1889.

Dr.		Capital and Liabilities.

Colombo, 31st January 1890.

THE VARYING STATE OF THE MARKET FOR CEYLON TEAS IN 1889

is thus shown in Messrs. H. A. Hertz & Co.'s Review of the Tea Market for 1889:—

January:—After opening slightly firmer than at the close of the year, have evinced a continually drooping tendency, most marked for Leaf Teas; really Fine Teas being the only exception, and these command full rates. Quality poor.—Lowest quotations for Leaf Tea 8½d to 8½d.

February:—The lower range of prices has attracted more demand, and prices show some recovery for all but the commonest grades and Teas of very indifferent character. Fine Invoices meet with good competition at full rates. Quality slightly improved.—7½d to 7½d.
March:—Demand and quotations are adversely affected by the unsatisfactory tone of the Indian Market, and prices have given way for all but the few teas of stand-out character. Quality indifferent.—6½d to 7d.

April:—Prices droop for all average grades, but finest descriptions continue to maintain a firm tone. Quality slightly improved.—7d.

May:—Further distinct decline most marked in Common and Low Medium descriptions, but steadier towards end of month; quality varying. Superior grades fairly firm.—5d to 5½d.

June:—Prices after opening steadily, on account of buyers gaining confidence from the large May deliveries relapse below the lowest point of the previous month for all but fine Teas. Auction rates towards end of the month show slight recovery. Quality indifferent.—5d to 5½d.

July:—Demand becomes more active and prices show gradual and substantial improvement, especially for finer descriptions. Quality better.—5½d.

August:—Offerings smaller. Competition brisk. Fine Invoices realize higher rates. Good Medium to Fines Medium Broken Pekoes, and Good Common to Good Medium Leaf Teas show a substantial advance. Common in good enquiry. Improvement in quality well maintained. 5½d to 5½d.

September:—Demand outstrips supply, and Common to Fair Common Leaf kinds experience a very considerable rise in prices; all others steady to firmer excepting Fine quality of Broken Pekoe, which is rather plentiful, and rules irregularly. Quality distinctly improved.—7½d.

October:—The brisk demand at further advancing rates continues until quite towards the end of the month, when prices commence to be adversely affected by the lower range established in the Indian Market. Quality remains satisfactory.—9½d.

November:—Demand has slackened, and prices experience a heavy fall from the highest point previously reached, about 4d for fine grades of Broken Pekoe and Pekoe, and more than 2d for Medium and Common grades of Pekoe and Pekoe Souchongs. Demand at the reduced rates becomes again more active. Quality falling off.—9d to 9½d.

December:—Are in moderate supply, and grades below 1s fully recover the decline of the past month and close firm with good demand. Better grades—except finest—are slow of sale and rule irregularly. Quality uneven, but generally fairly good.—8½d.

THE BLACKMAN SYSTEM OF WITHERING.

(By the "Peripatetic Planter.")

To the Editor of the "Ceylon Observer."

You were good enough to reprint in your issue of the 26th November an article by me under this heading from the *Indian Planters' Gazette*. In an editorial footnote, commenting favourably upon this reprint, you conclude as follows:—"But what a revolution has taken place in the ideas of tea curing since we were told that we must make provision of space for withering tea slowly by cool atmospheric air." Permit me to correct this suggestion. The Blackman System is merely a scientific application of cool withering,—cool, that is to say, as compared with the hot air of *chulals* or *dhools* such as we had to use in old days in wet weather. The warmth of the

manufacturing room air was never deemed excessive for withering purposes, and moreover was made the most of, so far as it could be without calling in mechanical aid. Every well-arranged factory had a withering loft above the manufacturing room, and had openings in the ceiling of the latter to allow the waste heat from the driers to ascend among the leaf. The drawback to this, however, was, that by not being able to remove the evaporated moisture rapidly enough from the withering room, the air therein became saturated and evaporation was retarded in consequence. The Blackman System removes this drawback by rapidly removing the evaporated moisture, and thus allowing evaporation to proceed naturally at its legitimate pace, without any stewing of the leaf in a saturated atmosphere. The few degrees of extra warmth derived from the waste heat of the manufacturing room give greater absorbing capacity to the air drawn by the Blackman fans over the leaf; and thus economize in the number of Blackman fans required; as the cooler the air the less absorbing capacity it has, and therefore the more of it must be passed over the leaf to produce like results in the same time. Hence the advantage of utilizing the 10 deg. or 15 deg. of heat obtained from the manufacturing room is a saving in fan-power, without any loss of speed; as compared with using the colder external air and more fan-power. Supposing the external air is at 80 deg., and the manufacturing room air at 90 deg. to 95 deg. that is 10 deg. to 15 deg. above the external air; it will be evident, that whilst the evaporating power under well-known laws is considerably increased by this gain of 10 deg. to 15 deg. there can be none of the risks of over-heating which attended the old-fashioned methods of artificial withering. Further that as compared with the old-fashioned methods, the Blackman System properly applied is, as a matter of fact, a system of cool withering, carried to the utmost perfection practice will allow.

One word more. You also ask "Ceylon planters who have tried the Blackman fan for withering to kindly favour you with the results." A note of warning is required here. The Blackman fan is not the Blackman system of withering, and those who order a Blackman fan or fans, and think that they have only to erect them and start them to gain all the advantages of the Blackman system, will probably take unnecessary expense and trouble to find out the distinction I have just made. The movement of large volumes of air (with due regard to all the local conditions, such as dimensions of withering room, position of doors, windows, sources of heat, shafting, motive-power, existing arrangement of trays, &c.) to be carried out efficiently and economically require the advice of those who have made a special study of the science of moving air in large volumes, and who have the results of past vast experience at their command. The Blackman Company realize the importance of this so well that they gladly supply working plans and estimates gratis, on receipt of the particulars given above; as then success can be insured at the minimum cost. Before accepting the opinion of any user of Blackman fans, it is well, therefore, to first of all ascertain, if those fans have been erected according to the Blackman Withering System under advice from headquarters, or, if they have been merely erected as prompted by more or less intelligent guess-work. In the latter case success or failure is a matter of chance with the odds largely in favour of failure; in the former, success is a scientific certainty.

PERIPATETIC PLANTER.

TEA has now almost entirely displaced coffee in Ceylon, and from a recent review of the administration of the Travancore State, it appears that the substitution is also taking place in Southern India. Within the last three years several coffee estates have been abandoned chiefly on account of the leaf disease, and as a result the value of the exports of tea has been doubled, having risen from 1½ lakhs to over 3 lakhs of rupees.—*Pioneer*.

SUGAR AND HEMP FROM PALMS.

Some palm trees furnish a sweetening juice. The most famous of these is probably the *Areng*, or sugar palm of Amboyna (*Arenga saccharifera*) which grows in India and the Archipelago. It is a superb tree, with pinnate leaves twenty-five feet long and is as handsome as it is useful. A number of species belonging to the different genera furnish a kind of hair of finer or coarser texture. It is found in the fibrous sheaths of the leaf-stalk and in the jagged edges of the leaves. Cables made of the black, tough fibres of the *Areng* are preferred by the coasting sailors of the Spanish colonies on account of their elasticity and durability; and they are, moreover, very fine. The hemp palm of Japan and (*Chamærops excelsa*) is available in the hands of the industrious people of those countries for making the finer brooms, light strings, and a thousand articles of daily use. Palms of coarser fibre, like the *Matagaba* of Brazil (*Leopoldinia piasaba*), furnish material for blinds, brushes, brooms, and the rollers of mechanical sweepers, which are much more durable than rollers fitted with steel teeth.—*Popular Science Monthly*.

THE TREATMENT OF TEA IN LONDON.

Messrs. William Walker and Sons, of Aberdeen, have made a communication to Mr. Goschen upon the subject of the treatment of tea on landing. They point out that to bring about any change which would have a permanent benefit on the revenue and the trade the first step must be to reduce the pressure on the Customs officials by separating teas brought into Britain for exportation from teas prepared and intended for consumption in Britain.

Say Messrs. Walker:—On the first there need be no Customs outlay or expense incurred; they can pass into a warehouse—unweighed, unmarked, and unexamined; while with regard to those teas prepared for home consumption, we believe that it would be better for all concerned that the duty were levied on landing at the ship's side, on each chop, mark, or invoice, upon some equitable basis of an approximation of the weight, thus insuring at once that studied care of the contents and condition of every package in which the present system so lamentably fails, and leaving to the grower, importer, or merchant, at his own time and in his own way, the weighing, marking, opening, sampling, taring, and selling of the tea.

To give an illustration regarding the present method of ascertaining weights, let us take a parcel of eighty chests of some specially prepared Indian tea. These chests have all been made of the exact same measurement, but the wood used is of varied kinds and densities, the result being that while the chests will vary in weight from 6 lb. to 8 lb. each, the net weight of tea in each chest will not vary as many ounces.

Then as to sampling, by the present system the Customs officials allow tea of greatly inferior character to be substituted for tea taken from the chest: in a lot of some thirty chests there will often be six or eight chests, in each of which will be found bags containing one or two pounds of rubbish not worth a tithe of the price paid. Is such a system equitable or just, or ought it to be countenanced by public officials?

But we should weary you by the instances we could furnish of the varied processes practised at present in the importation and sale of tea in London, all of which tend to the result of severely injuring the quality, greatly reducing its money value and gradually undermining that taste for fine tea which has been and is the notable characteristic of the great middle and humbler orders.

The system of turning out on the floor of a dirty warehouse every package of tea that happens to have been brought home in chests of irregular tares not only entails enormous expense, but permanently

injures the real value of tea, the exposure to the damp surroundings of the warehouse for however short a time being sufficient to begin, in the humid atmosphere of Britain, that process of decay in this delicate, perishable vegetable product, which in some sorts, specially of Ceylon growths, has now become so deplorably rapid, making certain kinds in a few weeks quite unmarketable.

No countenance should be given to any lowering of the present duty, for, besides the question of revenue, which is very important, it is emphatically a protective duty interposing itself as a barrier to the clearing for consumption of old and worthless teas. Large quantities of this sort have, we believe, been brought into this country chiefly for the purpose of gaining the difference on the medium of exchange, oppressing the Customs establishment by having to care for that which, by its being exported, yields nothing to the revenue.

The changes we have suggested could not be measured merely by the saving in the cost of one of the great branches of the service, for the moment that the growers of India, China, and Ceylon realise the fact that after a certain date no tea intended for home consumption will be allowed to pass from the ship's side until the duty has been paid, then a much-needed check will be placed on the character, quality and quantity of their exports, and the whole conditions of the trade will be altered and improved.

We plead for consideration of this subject on grounds of public policy, affecting equally the revenue and our interest in the East, but still more the interests of the public, for if the barriers which now exist are not removed, and if there are no fresh facilities created for enabling this delicate product to enter in its highest state of perfection uninjured into consumption in the country, we fear, that the taste for tea will fall away.—*H. & C. Mail*, Jan. 17th.

THE NEW SIROCCO.

(BY THE "PERIPATETIC PLANTER.")

Mr. Davidson has just set up two good-sized working models of his "Down-Draft" and new Tea Sirocco, in the show rooms of Mr. Geo. Ure, 132, Queen Victoria Street. These faithfully represent the full-sized machines down to every individual nut. They are capitally turned out, regardless of expense, and afford planters at home an excellent idea of the improvements in the apparatus and the working thereof. I believe a similar model of the "Down-Draft" will be sent out for exhibition to Calcutta, and another to Ceylon. The fan in the model "Down-Draft" is worked by a treadle; and tea is at hand, of various grades, down to the finest dust, to prove that it is undisturbed on the trays by the violent down-draft created by the fan. The fan on the new large-sized "Down-Draft" has been enlarged considerably, with a result that practically no more power is required to obtain the larger outturn yielded by the large-sized "Down-Draft" than is required to drive the smaller fan (at a higher speed), of the smaller "Down-Draft." The larger fan allowing a lesser speed to be used, minimizes the power required, which, as must be apparent, is a distinct advantage where the amount of power required is a serious item of consideration. Mr. Davidson has recently received a letter from a planter who reports that after six months' constant use, all the working parts of his "Down-Draft" Sirocco were found to be in as good condition as the day they were put up; this is satisfactory it will be admitted, and bears out what was predicted, as to the longevity which might be expected, due to the improvements in the construction of the stove. So rapid is the action of this Sirocco that fermentation has to be carried further than heretofore, before firing; as it is checked so promptly. This

alone is no trifling advantage, and was also predicted. It stands to reason that fermentation carried on previous to firing, is much more under control than when an element of guess-work is admitted, as, when part of the fermentation has to be allowed for during the firing. The orders for these new "Down-Draft" Siroccos, which Mr. Davidson is receiving daily, show clearly enough that the records of its first season have already made its reputation.

The feature in the new Tea Sirocco is a metal hood, ending in a metal flue or hot air duct. The advantages of this adjunct will be obvious, when it is pointed out that the great success of the No. 1 Sirocco was in great measure due to that type having a flue connected with the chimney by means of which flue the damp was drawn off from above the tea. In iron roofed houses, or in houses having a boarded close floor immediately above the Siroccos, unless some such flue is provided, it is found that the damp air from the drying tea does not escape from the house rapidly enough, and that by remaining stagnant above the dryer it retards co-operation. By means of the new hood and flue, which later can be conducted at will, either out of the building altogether, or else up through the floor into the withering room above the Tea Sirocco to all its other advantages can now claim this important one, as well as the No. 1 Sirocco. If the flue is conducted into the withering room above, and the Blackman fans are there used for rapidly changing the air, it will be seen that valuable heat which might be wasted is conducted without waste, to be turned to the best possible account. From what I hear, as to the companies already going in for the Blackman withering system, the virtues thereof do not seem to have lost any time in obtaining due recognition. It would seem as though every factory will be so supplied within two or three years at the outside, I must say the company is very liberal in the matter of drawing plans *gratis* (from information supplied them from the factories) showing the best means of adapting the system of existing conditions.—*Indian Planters' Gazette*.

PLANTING IN NETHERLANDS INDIA.

While we are having such wet weather here, the *Bataviaasch Nieuwsblad* says that the weather in Java, especially for this time of the year, when it rains copiously daily, is very dry. The drought in the interior of Java is causing anxiety. The young padi plants are drying up, and at some places padi planting has now to be stopped owing to the drought.

The Minister of Colonies at the Hague has drawn the attention of the Netherlands India Government to the bill introduced in the Legislative Council of the Straits Settlements for the preservation of coconut trees against destruction by beetles, and the Director of the Interior at Batavia has by circular requested the different Residents in Netherlands India where coconut is cultivated whether coconut beetles exist in their Residencies, and if so to what extent, and further, whether the ravages made by them are of such a nature as to render necessary the adoption of measures similar to those in the Straits Settlements.—*Straits Times*.

COFFEE IN THE PHILIPPINES.

There is no way of ascertaining the area of land in the Philippines occupied by coffee trees nor the amount of coffee raised annually, as the trees are scattered in various parts of the Archipelago. The largest plantations, says the United States Consul, are in the province of Batangas, island of Luzon, but many of the natives have a few trees

in their front door yards, under the shade of the plantains, that may yield three or four bushels of coffee berries. These are sold to speculators to help to make up a cargo gathered in this way from various parts of the Province.

The increase in the production has been marked within the past few years. In 1887 a little over 5,887 tons were exported, in 1888 about 7,501 tons, and up to the first of the present month 1,725 pounds had been exported of last year's crop. It is expected that the crop this year will be about 20 per cent larger than that of last year.—*American Grocer*, Jan. 1st.

AGRICULTURE IN THE STRAITS SETTLEMENTS: PEPPER, NUTMEGS, TAPIOCA, &c.

We have from time to time had occasion to remark that however much promise mining and manufacturing interests might give, it was to agriculture that the people of this colony must look to as the permanent backbone to the prosperity of the Settlements, and the truth of these reminders will be fully borne out by a study of the history of the growth of our Australian colonies, where, notwithstanding the importance of the mining industry, agriculture has been the making of the colonies. The discovery of gold no doubt greatly helped to produce this, as it brought a flow of capital and labour into the country which was sadly wanting, but after the gold fever was on the wane, it was found that gold could be got in a different form from that sought after, and the rapid rise in prices of land in and around the towns shewed that enormous profits did not pertain to mining alone, whilst the new industry had the advantage of being always a sure investment. Large farms were cleared and occupied, and the bleating of sheep and lowing of cattle replaced the mining mania. It is true that residence in Australia is more congenial both from climatic and social causes than it is in this Peninsula, but, on the other hand, the nature of the agricultural products in these eastern lands are such that only certain countries afford room for the pursuit, hence it is clear that the amount grown will always be within a limit rendering very outting competition almost impossible. The cultivation of nutmegs, cloves, pepper, tapioca, coffee, and paddy is restricted to a certain few places, and offers a fine field to capitalists. It has never been denied that the industry is highly remunerative, though a considerable amount of personal supervision and patience is necessary to ensure success, the greatest objection being the years of waiting till the early stages of growth have been passed. In the Settlements at present, it is estimated that out of an estimated area of about 900,000 acres, a little over one-third has been brought under cultivation, while nearly a half is quite fit to be so. That this land could be occupied and profitably cultivated there is no reason to doubt, and the time will come sooner or later, with the opening up of the Native States, when the Government will be compelled to give attention to the cultivation of cereals, such as paddy, which forms such an important factor of daily food, and to extend privileges to those willing to engage in its production. At present little or no attention is given to agriculture by the Government, and the difficulties in the way of obtaining information are too great to make that information much sought after. A grant for paddy seed to intending cultivators, with a few years free from revenue would probably assist in promoting the enterprise, and now that a science teacher has been appointed, classes might very advantageously be opened up for the study of agriculture and mineralogy as a prelude to the establishment of an agricultural and mining department, for which the development of the Native States will in time create a demand.—*Straits Times*, Jan. 18th.

COFFEE IN THE AGRAS has done well when a field of 90 acres has given 500 cwt. of crop; but this is the result of high cultivation costing as much as R150 per acre. Still that pays well with a crop of 5 cwt. and over per acre.

INDIAN TEA IN AMERICA.

(BY THE "PERIPATETIC PLANTER.")

I heard recently some items of news respecting Dehra Doon tea and Canada, which remind me that fact is sometimes stranger than fiction. Would it surprise you to learn, after all I have stated so emphatically here at various times, about a light liquoring flavour tea being the one with which to open the campaign in America, would it surprise you I ask, to learn, that the Canadians are taking so kindly to the light liquoring tea of the Doon, that about three-fourths of the total Doon crop is now imported into Canada direct? This was asserted to me recently as a fact, by one who is in the best position to know. The strange features in the case I have yet to point out. The first is, that by importing direct, the Canadians are said to be paying 25 per cent more than they could buy the tea for in London; and this without any corresponding saving or gain in transit charges. It appears that they will have the Tea packed in half-chests and not in chests. The distance for transport is greater than if the tea came via London. The American Railways, however, are so greedy for business, that they land the Teas in New York and put them in their waggons free of charge, all charges being confined to their own traffic charges. The U. S. Customs encourage this transport trade, by allowing the Teas to travel in bond. The Canadian merchants, too, accept invoice weights, merely boring a hole in an occasional chest, without otherwise opening or damaging it, to draw samples, and only weighing one chest in about a dozen. Very unlike London custom this. Well, notwithstanding the extra distance, and the proportionate extra cost of half-chests as compared with whole chests, the cost of landing the Tea in Toronto (the first market, I understand) is just the same whether it comes direct from India or via London; the warehouse and transhipping and other charges in London eating up the saving gained by the shorter distance. That is the second curious feature. The third is the outcome of the first. If the charges of transit are thus equalised, why should the Canadians prefer to pay 25 per cent more in first cost by buying direct, than 25 per cent less by buying in London? I do not, of course, hold myself responsible for the statements of my informant, I give them as I heard them, and I think they are sufficiently important, considering the well-informed source, to demand ventilation—as anything like an unnecessary tax of 25 per cent upon first cost is a handicap upon the gross amount of sales. Of course there will be individuals who would suffer by this ventilation, if it changes the channel of the supplies; but when the greatest good of the greatest number is in question, individuals have always to take their chance. Can it be that Canadians are so well informed already as to the damage done to Tea by the chests being opened in London, that they prefer, knowingly, to pay 25 per cent. more, and have their Teas direct and in cases intact, than 25 per cent. less, at the cost of quality? If so, they are capable of giving points and a beating to the London trade. Or is it that the Canadians argue, without a study of the facts of the case, that by purchasing direct, they must naturally (they suppose) save all the London middlemen's profits and charges, and must be getting their Teas cheaper than if they bought in London? It is quite possible that, arguing upon general principles, that may be the idea upon which they are acting—if that is really their idea, their general principles have led them astray as I have already shown.—*Indian Planters' Gazette*, Jan. 28th.

PRODUCTS AND INDUSTRY IN BRAZIL.

From the paper in January's *Contemporary* entitled "Brazil Past and Future" by M. G. Mulhall, we extract the following:—

Coffee is the sheet-anchor of Brazilian industry and wealth. Its cultivation was introduced by a poor priest in 1754, and Brazil now grows 60 per cent of the coffee of the world, the crop in 1885 being estimated at

390,000 tons, against 163,000 in 1855. The plantations cover 2,200,000 acres, with about 900,000 million trees. In good years the crop is valued at 22 millions sterling, nine-tenths being exported. Sugar is the oldest industry, the crop averaging 300,000 tons valued at £4,000,000. Cotton has declined of late years, the area being under 100,000 acres, and the yield from 30,000 to 40,000 tons of cotton-wool, worth about £1,500,000. The yerbaes or tea-forests* cover ten million acres, the annual product being 40,000 tons, of which one-half is exported, of the value of £500,000. India-rubber from the Amazon averages £300,000. The tobacco crop, from 100,000 acres, is estimated at 38,000 acres, valued at £1,400,000. Thus the total vegetable products make up about 30 millions sterling. Animal products are considerably under four millions sterling, and manufactures of all descriptions fall short of ten millions. There was a time when gold and diamonds formed principal products, when the Viceroy's horse was shod with the glittering metal, but at present the total product under these heads is barely £400,000 a year. If to the foregoing we add the earnings of railways, tramways, gas companies, shipping, banks, merchants, professional classes, &c., we find the total earnings of the nation approach a sum of 70 millions sterling per annum. We see, therefore, that the wealth of Brazil is rather a figure of speech than a reality. The earnings and industries of the Argentine Republic in 1884 amounted to £62,300,000, with a population of only 3,200,000 souls, or one-third that of Brazil. In the one country the average is nearly £20 per head, in the other barely £6, but wealth is so congested in the latter that two-thirds of the population are extremely poor, while many of the planters have enormous incomes. There is some similarity between the condition of things in Russia and that in Brazil, neither country being at all as rich as its neighbours.

Again as regards "Public Works," railways &c., we read:—

Engineering has done wonders in Brazil, and the traveller is astonished at the signs of gigantic labour and persevering energy amid a people and climate suggestive of indolence. The first railway was made in 1851, by Baron Mauá, to the Organ Mountains, and was soon followed by the Pedro Segundo, a main trunk line with numerous branches, which passes through the most magnificent scenery, carrying two million passengers yearly. The Santos and San Paulo line, made by a London company in 1860, at a cost of three millions sterling, is another triumph of engineering, being carried over the Serra Cubaton at a height of 2,700 feet by means of four inclines of one in ten, up which the train is drawn by a chain. The Bahia and Pernambuco lines, also by English companies, were made about the same time. Several new lines are being constructed in the interior, one of the most remarkable being the Misiones and Rio Grande line, of which Mr. O'Meara has recently opened some sections on the Upper Uruguay. At the close of 1888 there were 5,300 miles of railway in Brazil in actual traffic, of which 4,200 miles had been constructed since 1877. Some of them cost over £30,000 a mile, owing to the tremendous natural obstacles of the route. The total outlay exceeds 100 millions sterling, about 1,300 miles having been made by Government, including the Pedro Segundo line, an 4,000 by joint-stock companies, chiefly English. There are 7,100 miles of telegraph by land, besides cable, along the coast, from the Amazon to Montevideo. Except Ginty's roads near Rio Janeyro there are few high-ways; distances are so great and population so sparse. The overland route from Rio Janeyro to Goyaz for example, takes 120, and that to Matto Grosso 140 days. Nevertheless, all the principal towns have gas-works, schools and other marks of civilization. The municipal hospitals of Brazil are some of the finest in the world, that of the Misericordia at Rio Janeyro receiving 14,000 indoor patients yearly. Schools are not yet sufficiently numerous, only 15 per cent of children of school age receiving any instruction. Dockyards and arsenals are numerous and well-equipped, and many of the principal ports have been improved by Sir John Hawkshaw. * * *

British trade relations with Brazil do not increase much; they amounted last year to £11,800,000 against £10,800,000 in 1878. Internal commerce depends chiefly on railways and rivers; the freight on the former, as Colonel Church truly observes, is often excessive, and the rivers traverse very thinly peopled territories. The itinerary of the Amazon Company shows a length of 22,000 miles, including tributary rivers of which the Amazon has a hundred bigger than the Rhine. * * *

The danger of a labour crisis is probably exaggerated. It is said, indeed, that the coffee-crop last year fell off by one-third, consequent on the abolition of slavery. Some confusion must be expected at first, but the country will rapidly recover its energies. The United States at present produce twice as much cotton as before the abolition of slavery: there is every reason to expect that Brazil will likewise increase her exports, especially as the influx of Italians, Germans, &c., continues unabated.

THE EFFECT OF TOBACCO-SMOKE ON MEAT.

Cases of poisoning due to meat which seemed thoroughly wholesome have sometimes occurred, and have remained unexplained. In the *Revue d'Hygiene* of last month M. Bourrier, inspector of meat for the town of Paris, makes a valuable suggestion. He describes his experiments with meat impregnated with tobacco-smoke. Some thin slices of beef were exposed for a considerable time to the fumes of tobacco, and afterwards offered to a dog which had been deprived of food for twelve hours. The dog, after smelling the meat, refused to eat it. Some of the meat was then cut into small pieces and concealed within bread. This the dog ate with avidity, but in twenty minutes commenced to display the most distressing symptoms, and soon died in great agony. All sorts of meat, both raw and cooked, some grilled, roasted, and boiled, were exposed to tobacco-smoke and then given to animals, and in all cases produced symptoms of acute poisoning. Even the process of boiling could not extract from the meat the nicotine poison. Grease and similar substances have facilities of absorption in proportion with their fineness and fluidity. Fresh-killed meat is more readily impregnated, and stands in order of susceptibility as follows: pork, veal, rabbit, poultry, beef, mutton, horse. The effect also varies considerably according to the quality of the tobacco. All these experiments would seem to denote that great care should be taken not to allow smoking where foods, especially moist foods, such as meats, fats, and certain fruits, are exposed.—*Tobacco.*

WESTERN AUSTRALIA AS A SANATORIUM AND PLACE OF RESORT FROM CEYLON.

We have much sympathy with the subject of the letter of Mr. Waylen of Western Australia who passed through Colombo on his way to Europe by last Orient steamer. During our first visit to the Australian colonies in 1869, we wrote fully about Tasmania as the complement in so many ways to the island of Ceylon and as offering in climate especially, a very suitable change for tropical residents. Tasmania is indeed regarded very much as their Sanatorium by residents in Victoria, New South Wales, South Australia and even Queensland. The distance from Ceylon is however a great drawback and when on a visit in 1875 to Western Australia, during which we travelled some hundreds of miles into the country, the many attractions of its fine dry, and, in the cool season, bracing climate were fully realised and we wrote at length of the advantages offered by the trip from Colombo to Albany, and thence into the interior, or better still when the mail-steamers called at Freemantle. This latter arrangement has

* That is, forests of yerba mate or 'Paraguay tea.'—ED.

yet to come; but since our day, railways have been constructed, as Mr. Waylen describes, and the journey which took us nearly a week by a buggy and pair of horses from Albany to Perth, can now be performed in less than 24 hours, or comfortably in a couple of days. Few towns of its size are more attractive for beauty and convenience of situation or more healthful, than Perth the capital of Western Australia on the Swan River. Surrounded if not embosomed in vineyards, with a fine agricultural country stretching to the eastward, no one should be disappointed with a holiday trip to Perth at the best season. To such holiday trips would no doubt succeed closer connections and more permanent relations in many cases; and although we freely recognise the difficulty attending the substitution of Western Australia for England in respect of the education and bringing up of children; yet in some cases it is possible the former might be found the more convenient, or at least equally suitable should Mr. Waylen's idea of more frequent intercourse between the two Colonies be realized. On the other hand, we cannot forget that Ceylon, where "Europe amid Asia smiles", is so highly favoured with varieties of climates from the tropic warmth of Colombo to the medium hill temperatures between Kandy and Hatton (1,700 to 4,000 feet altitude) and up to the bracing mountain cold of Nuwara Eliya at 6,200 feet, that changes beyond the island are not so necessary to Europeans in this island as to sojourners in India. The difference of scenery, however, and the sunniness and yet coolness of Western Australia should be great attractions. The Colony, too is about to take a new start and has doubtless a great future, in the advantages of which it is quite likely visitors from Ceylon—induced to become settlers, say on some of the land grants of the Railway Company,—may participate. The extremes mentioned by our correspondent being rare, the merits of the climate are not exaggerated. Land is plentiful and cheap and with irrigation, carefully selected lots can be made to grow anything from the apple and cherry to the orange and the vine. For some time, it must of course be the day of small things; but in the hope of attracting attention to our nearest neighbour of the "Australias," we recommend to careful perusal, the letter of her patriotic colonist Mr. James Waylen.

COTTON IN DUMBARA.—We hear that probably never before in Ceylon has so fine a crop of cotton been seen as on Mr. Vollar's property, Karandagalla in the Dumbara valley. In Matale district too, the prospects of the cotton crop are very favourable.

FOR CEYLON TEA, says the *London and China Express* (an organ which favours China tea), unabated efforts are continued to push consumption elsewhere than in this country, and are meeting with success. There are many varieties as regards flavour to suit most markets where Tea is drunk, but there is still much to be learnt to bring the product (and Indian too) up to the best standard of China tea.

THE BOTANICAL EDITOR AND INFLUENZA.—Our contemporary—the *Family Doctor*—of last week amused those of its readers who had any acquaintance with *Materia Medica* by giving its most prominent page to an article on "the use of cocaine," illustrated with a large engraving of the coconut-tree—*Cocos Nucifera*. The reader, perhaps, wondered what the picture did there, but this was soon explained, for the article opened thus:—"Cocaine is a comparatively new drug; it is obtained from the leaves of the cocoa-tree, which is a genus belonging to the natural order of palms."—*Chemist and Druggist*, Jan. 18th.

THE COCO ISLANDS.—The *Rangoon Gazette* says:—"It is said that a strong effort is being made in Rangoon to form a syndicate to explore the Coco Islands." These, of course, are not the *Cocos* (Keeling) Islands, but the fever-haunts in the Bay of Bengal north of the great Andaman known as the Great and Little Coo. Some years ago the lease of these islands was advertised in our columns. Beside the coco palm, from which the islands are named, various tropical products have been tried there.

THE PEACH ORCHARDS OF CALIFORNIA.—We learn from an interesting article, by Mr. C. H. Shinn, in the *American Agriculturist*, that the Peach is one of the universal fruits of California, and grows everywhere, and that whatever future demands foreign markets choose to make upon this favoured land for Peaches can be abundantly supplied, as the Peach thrives in so large an extent of country. In the best fruit districts of the State, from 25 to 40 per cent. of the entire area planted is devoted to the culture of Peaches. The Peach tree in California often bears some fruit the second year from the bud, and gives a valuable crop the third year. Sometimes 20 lb. of fruit have been obtained from a tree fourteen months from the bud. In the Upper Vaca Valley, an orchard of 400 trees was planted in 1884, and gave \$60 worth of Peaches in the third year, and another orchard of 500 trees yielded £280 worth of Peaches in the fourth year after planting. The practice with the best orchardists is to thin the fruit, so as to let a four-year-old Peach tree bear 100 lb. weight of fruit, a five-year-old tree 150 lb., and a six-year-old tree 200 lb. But sometimes a six-year-old tree has been allowed to bear 300 lb. of Peaches without apparent injury. Leading growers say, that if they can be assured of 1 cent per lb. for their Peaches in the orchard, they can do well enough. There are some who think even a lower price would leave a margin for profit. The ambition of the most intelligent growers is said to be to provide cheap fruit for the million. They are aware that a great industry cannot be built up without wholesale methods and a willingness to accept small profits.—*Gardeners' Chronicle*.

AN ELEPHANT TRAIN.—A correspondent writes:—A novelty in the way of special trains left Mysore Station on Monday morning. Twenty elephants, big and little, were packed in vans with the sides caged and open to admit of plenty of air. The loading of these animals was very amusing to the spectators. Four baby elephants were packed in one van, and the last one of these, gave two fine tame female elephants plenty of trouble. They pushed the little one towards the van, and he screamed with rage and ran between their feet, rushing right and left; but the two mammas were not to be beaten, and the naughty screaming youngster was, after sundry struggles, landed safely with his brothers; but although conquered he was not silenced, for I believe the whole night he was heard pouring forth lamentations. Many of the medium-sized ones were troublesome, but on the whole they were most admirably managed by the indefatigable Mr. Sanderson, Superintendent of Keddahs, who remained all day in the hot sun encouraging and advising his numerous staff. The principal Europeans of the station were present as well as many natives. The 20 elephants are destined for Palghat, where they will be disposed of to the credit of the Mysore Government, but they will rest one day at Bangalore City Station, and then continue their journey by the Madras Railway by special train. I am sure all will wish Mr. Sanderson a successful journey with his valuable freight. We understand some of the elephants are too large for railing, and these will march to Bangalore. It is almost impossible to realize that these giants of the forest were in a wild state only a few months ago.—*Bangalore Spectator*,

DR. TRIMEN ON THE VEYANGODA
COCONUT TROUBLE.

Peradeniya, Jan. 27th.

You will be no doubt anxious to hear what I have done with the material I took from your estate on my visit there recently.

I have carefully examined the specimens of diseased leaves microscopically.

The breaking down and death of the tissues of the leaf in the diseased patches is well seen to be a gradual process of decay, but I have failed to detect, at any stage, the presence of a parasitic fungus as a cause of this destruction.

I am thus still of opinion that the partial or complete death of the leaves is due to some cause affecting the general health of the tree, and not to local injury caused by a vegetable leaf-parasite. I saw no sucking insects, either on my visit, or among those caught by your coolies; but I still think that, in at all events many cases, the morbid processes are set going locally by the punctures made by minute bugs.

So far as it goes, I think you may consider this opinion a favourable one. There is, so far as I can see, no reason to suppose the disease infectious or communicable from tree to tree, and thus likely to spread.

Not knowing the cause, I am unable to suggest any remedy, beyond careful attention to the general principles of cultivation and a liberal treatment of the trees.

—I am, yours faithfully,

HENRY TRIMEN.

—Local "Examiner."

BUMPER CROPS IN BURMA.

The area under rice cultivation in the ten chief rice-producing districts of Lower Burma is now estimated at 3,813,294 acres, or 182,214 acres more than the area under cultivation in 1888, and 5,154 acres more than was estimated last month. It is reported that (taking 16 annas as an ordinary yield per cultivated acre) there is a 20-anna crop in two districts, an 18-anna crop in one district, a 17-anna crop in four districts, a 16-anna crop in two districts, and a 15-anna crop in one district. It is estimated that there will be available for export 1,260,000 tons of cargo rice including what will be required for Upper Burma. In Upper Burma also the crops are generally good.—*M. Mail*, Feb. 1st.

A NEW COFFEE COMPANY IN THE STRAITS.

The prospectus of the "Castlewood Planting Company, Limited," which will be found in another column, is a wholesome change from the various mining schemes which have held the field for the last few years. The encouragement of agriculture in the Malay Peninsula is certainly of equal importance with that of mining, and is a steadier form of industrial enterprise; and the particular enterprise now under review, while necessarily subject to the risks which attend agriculture everywhere, has at least the advantage of a well-established and honest basis. Mr. Larken's "house of Castlewood" is well known to those Singapore people who visit Johore, and the considerable acreage of coffee under cultivation has always been regarded as one of the most prudently managed of Malaysian agricultural estates, while the owner's reputation stands deservedly high both with Europeans, with Asiatics, and with H. H. the Sultan of Johore. While, therefore, it is altogether beyond our sphere to assume that the coffee plant will always flourish, or that the price of the bean will always remain at its present level, or that Castlewood will always be well managed, it can be advanced from our own knowledge, supported by general repute, that the property proposed to be acquired is at present in good condition, is advantageously

situated for transport, and is held in such esteem by the Javanese that free labour at low rates has always been had to the full extent of the Castlewood requirements, even when other estates were quite unable to get that, and had to rely on costly and unsatisfactory Indian immigrants.

It will be seen that of the proposed \$150,000 of capital the vendor takes \$50,000 in cash and \$40,000 in shares, and that for four years the latter are "deferred" in such a manner that they will not get any return until the ordinary shareholders have received for four years ten per cent per annum, and until there is a reserve fund of \$15,000. Now in considering this deferring of shares, it must be remembered that the cash consideration of \$50,000 is equal to about \$275 per acre on the quantity of land in full cultivation a price at which, with good luck, a skilled person should be able to plant and maintain until fruiting point a coffee estate, including in the charge the cost of necessary buildings. What Mr. Larken takes in deferred shares is therefore not so much his actual outlay (which we may assume to be returned to him in cash), but rather the value placed on his rights over eighteen hundred acres of selected land, on his fortune in having a favourable situation and on the skill which has enabled him to do well with a small quantity of land in face of many difficulties, and which gives the probability of being able to do better with a large area to be opened free from those troubles which always mark the first stages of planting in any locality. It seems a reasonable bargain, and as the calculations submitted in the prospectus are based on what seems a low estimate of the yield of well-cared for and healthy coffee trees, and on a price much below what merchants anticipate for the produce, it is probable that the deferring of the vendors' shares will not prevent them from obtaining as much return as the others, a hope which, if realised, would mean not only much assurance of success to the Castlewood Company, but very great encouragement to the cultivation of coffee in the Peninsula. In fact if the Castlewood Company realises the prospects held out—an immediate ten per cent, with hopes of a very great increase—it may be assumed that the well-directed cultivation of coffee in the Malay Peninsula is one of the most hopeful forms of Eastern planting.

It is only proper to add that in planting almost everything depends on management. Not everything; for if coffee had remained at fifteen or sixteen dollars a picul (the price when Castlewood was opened), the most careful management in the world could not have assured more than a very moderate return, while conversely it follows that the planter who has seen in a few years the selling price of his product double itself, without increase in the cost of production, is enjoying an "unearned increment" of a similar kind to that which has set the whole tribe of unthinking Radicals howling around the ground landlords of London. But admitting that the prospects of highly remunerative coffee planting in Malaysia are based in the first place on a great and apparently lasting rise of price, it still remains that no price would be remunerative under bad management. If, then, the Castlewood Company is successfully floated, it will behave the directors to remember that the present vendor and future manager should not remain, the sole stay of the enterprise. An adventure based on the skill and prudence of one man is always in danger, and it is a characteristic of too many of the planting and mining adventures of the East that while spending freely on many things, they grudge to provide the

"second man," whose presence would be at once a means of fuller supervision and an assurance against the costly neglect which would arise from the illness or absence of the manager in chief.—*Straits Times*.

UNIFORM WEIGHTS FOR INDIA.

The Government of India have addressed the Local Governments regarding the practicability of securing a uniform system of weights in all India. That which appears the best solution, according to the Government, is the tolah of 180 grains, which is the exact weight of the rupee; the seer of 80 tolahs; and the maund of 40 seers. All railways have adopted these weights, and the tendency of trade will naturally be to follow this example. The Local Governments are asked to take the opinions of the principal trading Associations before forwarding their replies.—*Pioneer*.

NOTES ON PRODUCE AND FINANCE.

The paper on the "Tea, Coffee, and Cocoa Industries of Ceylon," read by Mr. Shand before the Colonial Section of the Society of Arts on Tuesday, did not attract a large audience. There were about twenty people present, but this was no doubt due to the bad weather of Tuesday evening.

According to an Indian contemporary Russian trade with India is improving, and the Russians are endeavouring to develop a direct trade with Indian ports instead of through London. If this be so there is some prospect of a direct trade in Indian tea with Odessa, and this enterprise will no doubt be pushed forward.

The letter of "S. N. S." in the *Financial News*, which we referred to last week, has called forth a reply from Mr. George Seaton. Final results of the season 1889 cannot be known till the closing of accounts, which is usually done about May, by which date it is anticipated that the larger proportion of the companies will, in spite of low prices, a not particularly favourable season, and the sharp competition of Ceylon tea, show very fairly satisfactory results. The shareholders of Indian tea companies and owners of tea estates are undoubtedly a very scattered body, and greatly lacking in the necessary cohesion; but they have latterly come a good deal more together, and show an increasing desire to work together for mutual interest under the auspices of their representative body, viz., the Indian Tea Districts Association, of St. Mary Axe." In a second letter Mr. Seaton gives the investments in tea as the following:—English registered companies, capital £5,000,000; Calcutta registered companies, capital £2,000,000; Private ownerships, capital probably £2,000,000; say, nearly £10,000,000.—*H. and C. Mail*.

REGULATING THE SUPPLY OF INDIAN TEA.

To the Editor of the *Home and Colonial Mail*.

Sir,—As we have now for some time past had the benefit of an influential committee regularly sitting as a feed-regulator to the machinery of the Indian tea market, it may prove interesting to compare results with last year, when the automatic principle of every man for himself was in force. Your columns have contained various references to the supposed merits of the new and improved plan; the brokers' circulars are alike laudatory and congratulatory; so that a comparison of figures cannot fail to interest, if not amuse those who have regulated minds. The quantity i

public sale since Jan. 1st to date was as follows:—

	1889.	1890.
First week ..	10,100 packages	13,137 packages
Second week ..	33,751 "	35,354 "
Third week ..	31,463 "	37,384 "
Fourth week ..	30,185 "	32,432 "
Total ..	105,499 "	118,307 "

It therefore appears that whilst under the old system the variation (omitting the first week) was under 10 per cent. from the highest to the lowest, it rose under the "regulation system" to a variation of 15 per cent.; and, furthermore, the market has had to absorb about 30 per cent in excess of the ordinary consumption. I am not by any means objecting to the principle of regulating supplies, but I think it is desirable that amid much trumpeting the above facts should not escape notice.—I am, &c., D. F. SHILLINGTON.

[Our correspondent's figures point to the necessity for exercising some control over the supplies. If the quantity of tea placed upon the market during the first three weeks of the present month is so great notwithstanding the control, it is reasonable to assume that without any restriction the quantity would have been much heavier. Our correspondent, however, views in quite a different light to ourselves the object which, as we understand it, tea growers have had in view. This is, we believe, not necessarily to reduce materially the quantity of tea at auction in any one week, but to endeavour to feed the market according to the varying requirements of buyers. At one time, from various contributing causes, very large sales have a less depressing effect on the market than at other times, when much smaller quantities are offered at auction. We believe, moreover, that importers, before deciding on the present step, came to the conclusion that it would be favoured by buyers as well as sellers, as they believe that nothing disturbed the confidence of buyers so much as an uncertain market, brought about by large and small supplies offered alternately, often without any consideration as to the requirements of the trade.—Ed. H. & C. M.]—*H. and C. Mail*.

COCONUT MILK: A NEW TRADE IN INDIA

Within the last few months a new trade has arisen in India and has attained extraordinary dimensions. About two years ago, a German chemist, Dr. Schlunk, discovered that excellent butter could be made from coconut milk. It is (according to a Bombay newspaper) pleasant to taste and smell, of a clear whitish colour, singularly free from acids, easily digestible, and an incomparably healthier and better article of diet than the cheap poor butters and oleomargarines of European markets. The manufacture is carried on in Germany, where one firm turns out from 3,000 to 4,000 kilogrammes daily. The coconuts required are imported from India, chiefly Bombay, in large and increasing numbers, and the trade seems likely to attain still greater importance.—*P. M. Budget*, Jan. 23rd.

SUPERSTITIONS ABOUT PRECIOUS STONES.

Agate quenches thirst, and if held in the mouth allays fever. It is supposed, at least in fable, to render the wearer invisible and to turn the sword of foes against themselves. It is the emblem of health and long life, and is dedicated to June. In the Zodiac it stands for Scorpio. Amber is a cure for sore throat and all glandular swellings. It is said to be a concretion of birds' tears. The birds which wept amber were the sisters of Meleagor, called Meleagrides, who never ceased weeping for their brother's death. Amethyst banishes the desire for drink and promotes chastity

The Greeks thought it counteracted the effects of wine. The amethyst is an emblem of humility and sobriety. It is dedicated to February and Venus. In the zodiac it represents Sagittarius, in metallurgy copper, in Christian art it is given to St. Matthew, and in the Roman Catholic Church it is set in the pastoral ring of bishops, whence it is called the prelate's gem. Cat's-eye is considered by the Singalese as a charm against witchcraft, and to be the abode of some genii. Coral is a talisman against enchantments, thunder, witchcraft, and other perils of flood and field. It was consecrated to Jupiter and Phœbus. Red coral worn about the person is considered a cure for indigestion. Crystal induces visions, promotes sleep, and insures good dreams. It is dedicated to the moon, and in metallurgy stands for silver. Diamond produces somnambulism and promotes spiritual ecstasy. The diamond is an emblem of innocence, and is dedicated to April and the sun. In the zodiac it stands for Virgo, in metallurgy for gold, in Christian art invulnerable faith. Emerald promotes friendship and constancy of mind. If a serpent fixes its eyes on an emerald it becomes blind. It is an emblem of success in love and is dedicated to May; in the zodiac it stands for Cancer, in metallurgy for iron, and in Christian art is given to St. John. It is dedicated to Mars. Garnet preserves health and joy. It is an emblem of constancy and is dedicated to January. This was the carbuncle of the ancients. Jacinth is also dedicated to January. Loadstone produces somnambulism, is dedicated to Mercury, and in metallurgy stands for quicksilver. Moonstone has the virtue of making trees fruitful and of curing epilepsy. It contains in it an image of the moon, representing its increase and decrease every month. Onyx contains in it an imprisoned devil, which wakes at sunset and causes terror to the wearer, disturbing sleep with ugly dreams. Cupid with the sharp point of his arrow, cut the nails of Venus during sleep, and the parings, falling into the Indus, sank to the bottom and turned into onyxes. In the zodiac it stands for Aquarius; some say it is the emblem of August and conjugal love; in Christian art it symbolises sincerity. Opal is fatal to love and sows discord between the giver and receiver. Given as an engagement token it is sure to bring ill luck. The opal is an emblem of hope, and is dedicated to the month of October. The Burmese believe the ruby ripens like fruit. They say that a ruby in its crude state is colourless, and, as it matures, changes first to yellow, then to green, then to blue, and lastly to a brilliant red, its highest state of perfection and ripeness. In the zodiac it stands for Aries. Some give it to December and make it the emblem of brilliant success. Sapphire produces somnambulism and impels the wearer to all good works. In the zodiac it signifies Leo, and in Christian art is dedicated to St. Andrew, emblematic of his heavenly faith and good hope. Some give this gem to April. Topaz is favourable to hemorrhages, imparts strength, and promotes digestion. It is an emblem of fidelity and is dedicated to November. In the zodiac it stands for Taurus, and in Christian art is given to St. James the Less. Turquoise given by loving hands, carries with it happiness and good fortune. Its colour always pales when the well being of the giver is in peril. It is an emblem of prosperity and is dedicated to December. In the zodiac it stands for Saturn, and in metallurgy for lead. A bouquet, composed of diamonds, loadstones and sapphires combined, renders a person almost invincible and wholly irresistible. All precious stones are said to be purified by a bath in honey.—*Detroit Free Press.*

ORIGIN OF CULTIVATED PLANTS.

CLOVES.—The clove originally came from the Moluccas Islands, and its cultivation two centuries ago was confined to a few little islands in this archipelago.

BANANAS.—This plant is probably a native of the West Indies, although "banana" was said as early as the 16th century to be a native name for it in Guinea. Authorities appear to differ regarding the matter.

CHICORY.—Chicory grows wild throughout Europe. The plant was known to the ancients, but no definite location can be determined as to where it was first known or used.

COCOA.—Cocoa tree, says one author, is perhaps of Egyptian origin; but De Candolle says, "I incline to the idea of an origin in the Indian Archipelago. The extension dates from not more than 3,000 or 4,000 years ago, but the transport by sea to the coasts of Africa and America took place in perhaps a more remote epoch." This author gives many reasons for holding this view of the origin of the cocoa and seems to have the weight of opinion on his side. [The *coconut* is, of course, meant.—*Ed. T. A.*]

POTATO.—Potatoes are native to South America, and were found growing wild by the earliest discoveries in that hemisphere. They were introduced into North America (Virginia) in the latter half of the 16th century, and into Europe by Spaniards, 1580-85, and afterwards by the English of Raleigh's time. Sweet potatoes probably originated in South America also.

PINEAPPLE.—Authorities generally concede that the pineapple is of American origin.

ALMOND.—"In Western Asia and some parts of Greece the almond may be regarded as indigenous from prehistoric time," says the author of an excellent work on the origin of plants.

APPLE.—Probably a native of Asia Minor, and its prehistoric area extended from the Caspian Sea nearly to Europe.—*American Grocer.*

THE WEATHER.

Writing to the London *Times* on "Modern Weather Wisdom," Sir R. P. Gallwey, of Thirsk, says:—

During the past year of grace 1889, I have kept a most careful record of the weather from day to day—I might almost say from hour to hour, save, of course, at night, when, I presume, the "clerk of the weather" himself takes a rest. Every day during the past year on which a forecast has been published I have had it pasted in a book, and every evening I have set down opposite each prophecy the actual weather of the current day, and this I have done in some twenty localities of our islands north, south, east and west.

Here is my summary. Out of the 312 weekdays I have a record of, I find the "clerk of the weather" is correct on 208 days and incorrect on 104 days—that is, he has guessed, I beg his pardon, I mean prophesied, correctly twice in every three attempts, or at the rate of only 66 per cent! I must, however, state that to make the summary easy for comparison I have thrown into the side of the scale that holds the "corrects" seem very doubtful forecasts, very doubtful indeed, so much so that an honest "clerk" would hesitate to claim them; still I wished at the outset of my task to give the gentleman who arranges the weather every advantage—an act of generosity I feel I have more than fulfilled.

Now for some experiments of my own in the way of weather prophecy. I copied out the weather forecasts each on a card to itself. I then put them all into a bag, shook the contents well, and each day the following month drew a card out haphazard and compared it with the state of the weather. I assure you, Sir, it was a neck-and-neck race to within the last few days of the month when the "clerk of the weather" won by a short length,

having the advantage of me by four "corrects" only; the fact being I unluckily had a run on "Rain and thunderstorms" out of my bag, while the "clerk" laid emphasis on "Fine generally and variable breezes."

I have also tried another system of weather prophecy which runs my friend the "clerk" very close, and this is to foretell for the next day the same weather as exists at sunset on the present one. I find by doing this I sometimes obtain a correct run of several days, each day succeeding the other with similar weather. Then comes a change and a fresh start; but in the meantime, by way of equalising matters, it often happens the "clerk" has wandered off the course and foretold a "change" before it occurs. Finding he is wrong, he is wont to fly for safety to the inmost recesses of his office in a sulk, and chalk outside the door—"Variable breezes, slight to moderate;" "Fair generally;" "Perhaps rain;" "Bright intervals;" "Weather uncertain."

Then bang comes a gale of wind and a snow-storm, though, save for the trifling affair of the snowstorm, our prophet doubtless considers his forecast a most reliable one, and once more rejoices. Certainly the above samples of weather prophecy are very, very safe ones, and most appropriate to our climate at times, though somewhat too general in their style to be called "prophecies." However, when all is said and done, the question is, Do our experts advance one iota in the accomplishment of foretelling the weather? I doubt it.—*Overland Mail.*

CEYLON PLANTERS' AMERICAN TEA COMPANY, LIMITED.

The advertised general meeting of this Company was held at 1 o'clock this afternoon (Feb. 12th) at the offices of the agents and secretaries, No. 9, Queen Street, Fort. After waiting for some time a quorum was formed by the presence of the Hon. J. J. Grinlinton (Managing Director), the Hon. W. W. Mitchell (representing the agents and secretaries of the Company, Messrs. Darley, Butler & Co.), Mr. Percy Bois (representing also Messrs. Alstons, Scott & Co., Mr. F. W. Bois, Mr. H. C. Buchanan, and Mr. A. C. Gibson), Mr. W. H. Davies and Mr. T. B. Campbell.

The MANAGING DIRECTOR took the chair, and said he was sorry to see such a poor attendance, but the fact that there was no dividend to declare and no particular business to be brought forward would account for the absence of the shareholders, coupled with the fact that this was mail day. This was the first meeting of shareholders, and it was called in accordance with the 45th clause of the Articles of Association which required that within six months of the date of the registration of the Company a general meeting should be held. There was a meeting of shareholders in Kandy on the 5th of July last, but that was an informal meeting, as the Company at that time was not incorporated. He held in his hand a list of shareholders, and he was sure it would be gratifying to the shareholders of the Company to hear that out of a total of 1,724 shares, there were only 10 shareholders who had not paid up their allotments, and 26 who had not paid up their first call, thus making only 36 defaulters altogether, which he thought was very creditable to the Company. The number of shares that had been taken, however, was insufficient to work the Company in a thoroughly satisfactory manner, and they ought to have at least 3,000 shares to be in a good position. It was, therefore, hoped that their friends in Ceylon—more parti-

cularly the planters—would come forward and take the balance of the shares which were so necessary to enable them to have a thoroughly good start in America. Most interesting letters had been received from Messrs. Watson and Farr, (the agents of the Company in New York), and from Mr. Pineo, showing the progress that they had made up to date. Some of the letters were on the table, and extracts from them would no doubt be read.

The Hon. W. W. MITCHELL, representing the agents of the Company, apologized for fixing the date of the meeting on a mail day, but owing to the numerous meetings of other Companies about this time they had to take whatever day was available, and they could not put it a day later or they would have exceeded the six months within which time the meeting must be held in accordance with the provisions of clause 45 of the Articles of Association which require that a general meeting shall be held within 6 months of the incorporation of the Company. The annual general meeting of the Company would be held as soon after the 30th June as possible when the accounts and balance sheet to that date would be presented to the shareholders. Mr. Pineo with two natives, sailed from Colombo on the 20th August last via Australia, San Francisco and Vancouver, and after visiting some of the principal towns in Canada and the States, arrived in New York at the beginning of December, where in conjunction with Messrs. Watson & Farr, the New York Agents of the Company, arrangements had been pushed on for the organization and working of the Company's business. Premises that were deemed to be admirably adapted had been secured at 22nd Street between Broadway and 5th Avenue. Another packing machine had been ordered (the first one sent having been lost with the steamer taking it) and the necessary appliances obtained, whilst every effort was being made to make the place attractive and to ensure the effective starting of the work. From the 8th of November to date four shipments of tea had been made, and another was now ready. When this had been shipped on the 17th instant an aggregate of 18,773 lb. would have been sent forward, and this would be followed up with further parcels at frequent intervals, regulated by the advices received and the offerings in the local market. On the 16th of November last Mr. Pineo wrote from Vancouver as follows:—

We made the port of San Francisco on the 26th October and I have, since then, visited Portland in Oregon, Taona in Washington Territory, Victoria in Vancouver Island, and lastly this place.

You are doubtless aware of the fact that only cheap low grades of China and Japan teas are generally sold on the Pacific coast, and that the vested interests are not only large but deeply rooted, and that in coming here we are endeavouring to get our teas into a section where they are, almost, wholly unknown and much dearer than the teas generally used. In the cities just mentioned it would seem almost impossible to get any one to take up our teas and push a trade in them on conditions that would be acceptable to your Company. Propositions, in writing, are to be made and forwarded to New York when I can submit them to Messrs. Watson & Farr and have time to give them impartial and necessary considerations, copies and replies will be forwarded to you in due course.

Messrs. W. S. Coleman & Co., formerly doing a large business on the Pacific coast failed last year, but their successors were visited by me, and they will, I anticipate, undertake to act as your Agents on conditions that will be made known to me in New York, and which will be communicated to you later on.

My route hence to New York has been altered, and instead of going via Montreal I go by Winnipeg, St. Paul's, and Chicago. This change is made in the interests of the Company and partly because I have received numerous letters to business men in the two last named cities who may be of very great service to the interests I am endeavouring to represent.

Communications have been opened up by me with the Canadian Pacific Railway Company with a view to get that Company to arrange with one of the many lines of steamers touching at Colombo and Hongkong to grant through Bills of Lading from Colombo to Vancouver but final arrangements must be made by the Head Office at Montreal.

It has been my good fortune to make the acquaintance of Mr. N. C. Davies who is prominently connected with the Northern Pacific Railway and who was very greatly impressed with what I related to him about our teas. He has given me several introductory letters to men holding high position, in the Company abovenamed and will use his best endeavours to assist me in getting our teas on all the sixteen Dining Cars of the Northern Pacific Railway system.

I became acquainted in San Francisco, with a son of Mr. Armour of Porkpacking fame who gave me many letters of introduction to influential business men in St. Paul's and Chicago besides one to his father's firm.

Vancouver city, the terminus of the Canadian Pacific Railway and the starting point of the Canadian Pacific steamers plying to Japan and China is growing very rapidly and is fast approaching a point when it will become the chief city of the Pacific coast. In its near neighbourhood are minerals of all kinds, among them may be mentioned gold, silver, iron, coal, etc., and its supply of lumber is comparatively inexhaustible. Soon the Northern Pacific and the Southern Pacific Railways will extend their roads into it, and it seems destined to become the chief distributing point on this Coast. Mr. Abbott the Chief Manager here of the Canadian Pacific Railway, tells me they have landed silks and teas in New York in twenty-seven days from Hongkong and he believes our teas can come over his line as quickly and cheaply to Montreal as by the Suez Canal and London. This leads up to my having to state that I have made, what I believe to be, a very important connection here.

The firm of Oppenheimer Bros. have given me a small order. The firm is represented to be worth £100,000—and it is doing the bulk of the wholesale business here. One of the firm is the present Mayor of the city which office he has occupied for three consecutive years.

This letter was accompanied by an order from the firm named, which had been executed, he was happy to say, and the tea sent out for transshipment from Hongkong to Vancouver.

Mr. DAVIES asked if the teas that were being sent were all black teas.

Mr. MITCHELL replied that they were. The Directors had decided that for the present they should confine their attention to black teas. They had, however, had an offer from Mr. Drummond Deane to send green teas, and he certainly intended to recommend the Directors to take charge of Mr. Drummond Deane's consignment, and let it be sent to America on his account, and they would at all events see the results of it. He did not think it would interfere very much with the sale of their black teas, to which they were giving special attention, and they would have the advantage of knowing which teas took best. Whether they would follow it up by recommending the making of green teas in Ceylon, and undertake the shipping of them, was a matter which must depend very much upon the result of the present experiment. —Messrs Wattson & Farr wrote on Dec. 13th last:—

Mr. Pineo has decided upon a shop on 22nd Street between Broadway and 5th Avenue one of the very best locations in the City and we have ordered it leased from 1st Jan. 1890 until 1st May 1891 at the

rate of \$4,000 per annum. Almost all leases end here on 1st May. This property is very cheap as rents go, and we quite agreed with Mr. Pineo, that it was best to get a really good and well located shop, even if we would have to curtail advertising or some other expenses. We have ordered the lease in the Company's name, we of course guaranteeing rent, as we will have to do for all engagements.

Mr. Pineo is looking after packets, advertising arrangements &c. &c. He much regrets that the Tea Packing Machine has not arrived yet, as he cannot order the packets until he sees it.

We find Mr. Pineo a very pleasant gentleman, and shall have much satisfaction in co-operating with him in any way. He will no doubt write you fully in a few days.

Another letter came from Mr. Pineo, but he had sent it upcountry to the Chairman of the Company, who had not returned it, although he wrote for it twice and telegraphed yesterday. He was afraid the Chairman had been away from home, but the letter was probably then on its way down and when it came he would make the necessary extracts and hand them to the Press for the information of the shareholders. There was really no other actual business to bring before the meeting. All that was contemplated by holding the present meeting was to afford an opportunity of giving information to the shareholders. Not very much time had yet elapsed out of which to accomplish a great deal, or even to receive much information from the other side as to what had been done. It must be remembered that although the Company was a Ceylon Planters' Company, its operations were being carried on on the other side of the world, and it took a considerable time to communicate with America. Everything, however, was being got in readiness for a good start. They had first-rate premises, and, as was evidenced by the correspondence, they had got first-rate people to look after the interests of the Company, and, what was of much importance, they were ready to co-operate with Mr. Pineo to the fullest possible extent. They had gone on supplying Mr. Pineo with shipments of tea, and, as he had stated, about 18,000 lb. would have been sent when the "Dacca" sailed in a few days. The shipments were made on through bills of lading to New York with transshipment at London. They would be guided by the advices they got from New York as to the quantities they would go on sending from week to week. They were quite ready to send on as much as ever they were likely to get through, but they would wait a little longer for more information as to the quantities they found to be saleable. The teas which had been sent were bought to match standards which were very carefully selected and decided upon by the whole of the Directors, and there was not the least doubt as to their giving satisfaction because these same teas were fully gone into with Mr. Pineo before he left, and samples of the standards were taken with him. He thought the prospects of the Company were very promising indeed. Many people asked him if they were likely to receive dividends? Well, judging by the prices which had been quoted from America he did not see that they could fail to have fair dividends upon the capital invested after a little time had elapsed. At the very outset, of course, their expenditure must be considerable in fitting out an establishment such as they had got to make complete, and in advertising and other charges, but when once the Company and its teas were known the necessity for going on expending money at that rate would, of course, cease. At the present time the principle they were going upon was to ship the teas to the agents in New York without drawing against them, because they now had the capi-

tal of the shareholders in hand to the extent that it had been called up. Further calls would have to be made before long in order to admit of their sending more tea, and in order to place the agents in New York in funds for the expenditure which had to be incurred. Had the shares been taken up to a larger degree than they have been, it might possibly have been found unnecessary to call up more than a very limited portion of the capital. It might be that if, as their friends wrote from New York, they anticipate that a considerable number of shares may be taken there that they would not find it necessary to call up the whole of the capital, but at this stage it was not possible to say whether this could be altogether adhered to. The total number of shareholders was very large—355, and the number of shares held by them altogether 1,724, so that the number held by each individual was not a great many on the average. He thought, therefore, that they might very fairly expect the 355 gentlemen who had taken shares to take a larger number perhaps without hurting themselves very much, especially as the prospects appeared to be so promising. He spoke with all sincerity when he said that he believed it would turn out to be a good investment of capital. Of course if they were to be limited and hampered by want of funds then the result might be somewhat different, but he trusted that that would not be the case.

The CHAIRMAN briefly supported all that Mr. Mitchell had said, and the meeting then concluded with a vote of thanks to the Hon. Mr. Grinlinton for presiding.

THE TALGASWELA TEA COMPANY OF CEYLON, LIMITED.

DIRECTORS' REPORT FOR THE YEAR ENDING 31st DECEMBER 1889.

The Directors have pleasure in placing before the shareholders their Second Annual Report, together with a duly audited statement of the Company's affairs and financial position, as on 1st January, 1890.

During the past year 206 acres of very choice land have been selected, from the available forest, and opened under Tea. This added to the 510 acres opened in 1888, gives a total of 716 acres under Tea.

According to the Visiting Agent's Reports, planting operations have been successfully carried out, and the growth of the bushes is most satisfactory. A large portion of the Estate gives promise of an early yield of leaf, and it is hoped that 25,000 lb. of made Tea, if not more, may be harvested during the current year.

The Directors are pleased to announce that instead of 500 acres under Tea, as originally proposed, there is one compact block of 716 acres now planted in accordance with their Report for the previous year.

The tabulated rainfall for 1889 gives a Total of 241.13' in 158 days, which contrasted with previous year, shews an excess of 62.93'.

The past twelve months may therefore be looked upon as abnormally wet, although the rain appears to have been well distributed over 158 days.

A Factory for present requirements and a permanent Superintendent's Bungalow have been erected on the property during the past year, costing respectively,

Factory and Machinery, etc. R13,344.77

Superintendent's Bungalow and Outhouses 2,115.86

These buildings and machinery are of a good permanent character and suitable design.

Your Directors confidently hope that the Water Supply may be made adequate to the power needed for Rolling and Firing Tea during the next year or two, and until it should be found necessary for an Engine to be put up.

Towards the latter end of 1889, Mining operations have been commenced by parties who are willing to work with their own capital giving 10 per cent of whatever is found to the Estate. Up to the present, the

prospecting parties have come upon several indications of Minerals which are now laid before the General Meeting, amongst them may be noticed Plumbago of a good quality.

Estimates for the Current year's expenditure and Crop Returns have been framed, and are submitted to the Shareholders.

The Directors are glad to say that the Railway to Bentota will be open for traffic in a few months, and that Surveyors are now at work on an extension of this line to Galle. It is perhaps needless to add that facilities for transport by rail have increased the value of landed property very considerably in the Southern Province; as an instance of this, it may be stated that at a recent sale in Galle, steep rocky land in the neighbourhood fetched over R33 per acre, which could have been bought some years ago for the upset price of R10.

The last call of R30 per share made in January 1890 will about cover this year's Expenditure after which it is hoped that dividends may be looked for.

Messrs. T. C. Owen and G. W. Subren retire from the Directorate and offer themselves for re-election.

By order of the Board of Directors,
A. SCHULZE, Secretary.

Colombo, 4th February 1890.

PLANTING IN TRAVANCORE.

Mr. Berry has returned from his visit to the Travancore tea districts. He landed at Quilon and was accompanied to Central Travancore by Mr. D. G. Cameron, who is at the head of the Quilon Agency house. Mr. Berry is well pleased with the tea gardens he saw of Messrs. Valentine, Marshall, Miller, Monour, Mackay, and he found plenty of room for extension by new-comers with abundance of good land available in a well-roads country. Some of the old coffee properties in the abandoned estates are a melancholy sight—notably Strathmore, which had once 1,500 acres under cultivation.—Mr. Jacob of the Travancore P. W. Department returned by same steamer as Mr. Berry, *en route* on a holiday trip to Australia.

LETTER FROM MR. W. WATSON REGARDING THE NEW ZEALAND AND SOUTH SEAS EXHIBITION.

Dunedin January 6th.

A. Philip, Esq., Secretary Planters' Association, Kandy.

Dear Sir,—I wrote to you last on December 5th (press copy enclosed), and have again the pleasure of informing you that the number of visitors to the Association's court in the Exhibition continues to surpass expectations. The following are the gross amounts taken at the Kiosk per diem since the opening:—

November 26th, £2 5s 3d; 27th, £1 11s 6d; 28th, £2 19s 2d; 29th, £2 9d; 30th, £2 1s 3d. December 2nd, £4 2s 3d; 3rd, £1 10s 9d; 4th, £1 17s 8d; 5th, £1 7s; 6th, £1s 9s 10d; 7th, £2 18s 6d; 9th, £2 7s 8d; 10th, £2 6d; 11th, £1 12s 9d; 12th £1 12s; 13th, £1 16s; 14th £2 9s 7d; 16th, 18s 6d; 17th £3 6s 5d; 18th, £4 7s; 19th, £1 12s 3d; 20th, £2 7s 5d; 21st, £3 5s 3d; 23rd, £2 3s; 24th, £1 9s 4d; 25th, £5 10s; 26th, £5 19s 3d; 27th, £2 16s; 28th, £4 3s 9d; 30th, £2 11s; 31st, £3 12s. January 1st, £8 2s; 2nd, £9 6s; 3rd, £5 3s; 4th, £3 14s 9d.—Total £107 9s 7d.

The above sum represents roughly, 8,598 cups of tea sold, and many cups of tea have been given without being charged for.

The falling away in the attendance at the Exhibition may however be now anticipated, but the Tea Fund Committee may be assured that their Court has already fully answered the purpose for which it was got up, and that Ceylon tea, instead of being an article known only to a few in New Zealand, has now become known very widely. I must here inform you that after due consideration Mr. Begg and I agreed to raise the grade of the tea forwarded by you for use in the Kiosk. Of its own class the tea is excellent, prob-

ably, as good as any of its class, but we concluded that, in view of the strong opposition by the blenders to pure Ceylon tea, it would be unfair to the Association's interests to let a pekoe souchong stand the test, and so it was enriched by a few pounds of pekoe No. 1.

The natives have behaved admirably, working from 10 a. m. to 10-30 p. m. each day. Last week a servant girl was engaged to wash up the tea dishes, the long hours and hard work being too much for the Sinhalese without assistance.

Enclosed please find a list of the exhibits. Judging will soon take place, and Certificates of Order of merit will be issued, but no medals.

By book post I forwarded to you and to Mr. Kelly two copies each of photographs of the Ceylon Kiosk taken by Mr. J. V. H. Owen of Maturata. Mr. Owen expressed himself as well satisfied with what had been done here.

I regret that the case of Photographs by Mr. Skeen forwarded by Mr. H. Mackenzie of Melbourne has gone astray, and a box containing tea has been delivered in its place.

Every effort will be made to recover the Photographs. I shall be glad to have your instructions as to the disposal of the Kiosk at the close of the Exhibition, The Kiosk itself cost £50, and the erecting, decorating, flooring etc. £50 10s, besides curtains and other material. If the Tea Fund Committee look forward to being represented at the New York or any future Exhibition it might be worth their while to have the Kiosk taken to pieces and shipped to Colombo for future use. Fresh painting will always make it as good as new for Exhibition purposes, and it would be a pity to let go for a trifle an article which has answered its purpose so well here.

Perhaps the Committee will fix a price limit and instruct me so that in the event of my not being able to obtain that or a higher figure here I should send the Kiosk to Colombo.—I remain &c.,

(Signed) W. WATSON,
Inspector, Colonial Bank of N. Z.

TEA.—Amunamulle estate; Blackstone; Blair Athol, F G A Lane; Brunswick; Castlereagh, L H Kelly; Court Lodge; Dalhousie, G H Green; Dedugalla; Dunedin, F T Turpin; Eastland; Emelina, Colombo Commercial Company, Limited; Gallebodde, Mackwood & Co.; Great Western; Hethersett, K Mac andrew; Holmwood; Inverly, Scottish Ceylon Tea Company, Limited; Kenagaha Ella, H H Bastard; Kintyre; Kirkoswald, C Carew; Labookellie; Mooloya, Colombo Commercial Company, Limited; New Peradeniya, R Anderson; Rookwood, C S Armstrong; Sembawatte, D Fairweather; Theberton, T J Grigg; Tillyrie; Tommagong, J McLaren; Torwood, D A Wilson; Vellai Oya; Wallaha, G A Talbot; Buchanan, Frazer & Co., (the handsome ebony case sent with Messrs. Buchanan, Frazer & Co.'s exhibit deserves special mention); William Law & Co., Lee, Hedges & Co.

CINCHONA AND SUGAR IN NETHERLANDS INDIA.

In Java, the cultivation of sugar-cane now meets with difficulties owing to a disease called *sereh* striking at the roots of the plants. A planting expert at Samarang has, says the Batavia *Nieuwsblad*, ascertained that the evil extends also to the Straits Settlements, and that, too, in an aggravated form. The disease makes rapid headway in Java, where it has spread from the central provinces to the eastern end of the island. Wherever it has gained a footing, the havoc wrought reaches alarming proportions, and no effective remedy suggests itself. The planters are at their wit's end how to cope with the foe.

In the Preanger (Java), large stretches of land taken up, to be planted with cinchona, have been abandoned, and have lapsed to Government, owing to the decline in the price of bark. No capital could be raised for cultivation, and hence the land proved a burden to be cast off as quick as possible.—*Straits Times*, Feb. 4th.

PLANTING IN THE LESSER ANTILLES, WEST INDIES.

Besides the sugar-cane and cocoa-nut palms there are industries connected with fruits, fibres, spices, annatto, arrow-root, pepper, maize, medicinal plants, scent-producing plants, coca, ramie, tea, tobacco, and many others well suited to the soil and climate.

It is well known that in former days large fortunes were made by sugar planters in the West Indies. Now, however, even the best estates do little more than give a small return on the capital invested, while many cannot even do this. It would be unwise, therefore, for the West Indies to confine their attention exclusively, or, indeed, largely to the sugar-cane. Already a change is taking place. Jamaica has pimento, coffee, tropical fruits, cinchona, dye-woods, annatto, cacao; Trinidad has cacao, cocoanuts; Grenada is almost exclusively cacao and spices; Montserrat is noted for its lime plantations and lime-juice; while Dominica exports concentrated lime-juice, cacao, coco-nuts, as well as oranges to the neighbouring islands. The tendency is for the cultivation of the West Indies to become more and more diversified, and it is well it should be so.

With such good markets for produce of all kinds in the United States and Europe, it is evident that West Indian planters could regain much of their former prosperity if only they adapted themselves to the new order of things. To assist them in the development of new industries, Government botanical gardens are in course of being established, under the auspices of Kew, in every island, and from these new plants and information respecting their cultivation are being widely distributed. In such a work enterprising governors, such as the late Sir Anthony Musgrave, and the present Governor of Trinidad, Sir William Robinson, and others, have taken an active part. It is not, however, as regards industrial subjects only that interest in the West Indies has revived of late. The publication of Griesbach's "Flora of the British West Indian Islands" in 1864 (one of the series of colonial flora projected by the late Sir William Hooker) was for a long time the only effort made in the cause of botanical science in this part of the world. Since that time, both the fauna and flora have received systematic attention in this country and in the United States, and after a lapse of nearly two hundred years we are beginning to have a clear idea of the distribution of life in the Caribbean Archipelago.

D. M.

—*Nature*, Jan. 23rd.

COCONUT CULTIVATION AND MANURING

In my last, I promised to give the best means I have found of manuring coconut trees. There may be good fertilizers and the best soils, but still manuring should be done in such a way as to get the most out of the least expenditure. The heaping of rubbish round the trees is proved to be injurious to them in the long run. A system of manuring the whole land cannot be carried out, on account of the heavy expenditure it would entail on a cultivator. The best and the cheapest way would be to manure round individual trees. But with what manure, and how should it be applied? There are a host of manures, oil cakes and special fertilizers, but the common kind of manure we find in our coconut-growing districts is cattle dung. Unlike other cultivators, the coconut planter has the advantage of keeping a pretty good number of cattle on his plantation. Without entering into either special manures or compounds of different fertilizers, I shall dwell upon the simple dung obtained from our cattle.

Before applying manure to trees, it has been found useful to dig a trench round them. The trench should be made just a foot and a half away from the stem of the tree. If it is cut nearer, it might impair the growth of the tree by giving it a severe shock from the loss of so many roots. I have seen cases where trees have been damaged for a number of years by digging round too near the stem. So a space of nearly 1½ feet should be left untouched round the stem. For ordinary purposes of manuring, the trench should be dug about 3 feet or more wide and from 5 to 8 inches in depth.

The cattle should be tied to the trees overnight till the trenches are sufficiently stocked with manure, and then the trenches should be covered up. This method of manuring has an advantage in utilizing the urine, which is generally allowed to run to waste in this country for want of suitably built cattle sheds.

The manure obtained by tying two pairs of buffaloes from 5 days to a week is considered sufficient for one tree, and in the case of neat cattle, an additional pair should always be employed during the same number of days.

There is another, though a trifling operation, which adds material value to the manure. It is the spreading of a little earth every morning over the deposits until they are finally covered up. This prevents the loss of much valuable material, which would otherwise escape from exposure. W. A. D. S.
—Ceylon "Examiner."

PLANTING IN PERAK.

Batang Padang has made very satisfactory progress during the year. A great many settlers have come in, and have formed gardens in different places, especially round Tapah. They extend for three miles along the Teluk Anson road, and will, I think, compare favourably with any similar plantations in the State. I have distributed about 14,000 Liberian coffee plants, and small quantities of pepper, tea, and Para rubber, besides coconut plants, during the last two years. They all seem doing remarkably well; some of the coffee is very fine indeed, and that first planted is now coming into flower. So far I have seen no sign of leaf disease. I have now some 20,000 130 000 Liberian coffee plants growing in the nurseries, and am planting more seeds, as I have applications for far more plants than there are in the nurseries. On the hill on which the Magistrate's quarters stand I have planted out several acres of land, which is making very good progress. On the hill behind the bungalow I have cleared six acres of land, which is being planted up with pepper, as I get the plants. My intention is to use this pepper garden chiefly for propagating purposes, as the great difficulty at present is to get healthy plants. The pepper planted by Haji Ali in June, 1886, is now very fine, and is loaded with fruit. That planted last year by him and others is also doing very well. I find that pepper planted against dead wood posts is far finer than that planted against having

dedap trees. In every place where the two supports have been tried together the result is the same. It appears as if the roots of the dedap rob the pepper of moisture nourishment. This may account in some measure for the miserable, sickly appearance of the pepper I saw recently at Ohangkat Jong. There are about 130 gardens in all round Tapah, and a few of the first settlers were assisted to the extent of about \$290 in all; of this they have repaid about half, and will repay the balance this year. The padi crop has been good, and there were two abundant fruit crops during the year, durians being particularly plentiful.

The district is now receiving considerable attention from miners, and there are several prospecting parties at work. The mines are doing well, but have hitherto been much hampered by the heavy cost of transport. I have done what I could to improve certain of the tracks to different mines, and the miners themselves have been very active, and have now got very good jungle paths to the chief mines. The bridge road to Kachu will, I think, prove a great convenience and help to the people working in that valley. It opens up a large amount of land, both mining and agricultural. I hope hereafter to continue this path from Kunoh, past Brumin to Kwala Woh, a distance of about 3½ miles. The cart road to Pahang hill country is opening up many miles of splendid land, and I hope to see the road very largely used when completed. The so-called plateau should, and I hope will be, the sanatorium of the Straits. Having a mean elevation of 4,000 feet, with a good cart road up to it from Tapah, and railway communication between there and the port, it will be within easy reach of every one. I should think that most of the European vegetables could be grown there for the supply of the Straits markets. From what I have seen of the climate, it is far superior to that of the more isolated and exposed hills, such as those of Penang and Larut. The rainfall appears to be less, and it is not swept by the winds which make a sojourn at some of the present hill stations so unpleasant at times.—Perak Government Gazette.

CHINA TEA FOR LONDON.—The following important piece of news occurs in a London letter to the *Indian Planter's Gazette*:—

A very important item of news was announced in the room this week, when it was officially given out that Mr. Thorne would retire, and import no more tea after this season. It is currently reported that he has recently been very successful upon the Stock Exchange, and that there are also other private reasons for the step. This piece of news means a great deal. The heaviest importer by far of China Tea is thus withdrawn from the market—and further, the one too, whose huge sales were so frequently rushed forward at the last moment, as to be a continual source of anxiety to all sellers. The effect of this will be felt in many ways. Chinas will be in diminished supply, as the Chinamen on whose account so much of Mr. Thorne's Tea was reputed to be held, are said to be sick of losing money, and will, not improbably, considerably reduce their speculations with Mr. Thorne's retirement. Indeed, some China "hands" go so far as to say that this is the beginning of the end of China Teas. That they cannot be made and sold at present prices without loss, and that they will cease to ship, or even to manufacture for London unless prices recover. The removal of the most disquieting factor from the market is, however, quite sufficient in itself to justify the sense of relief which is felt on the strength of the above news, without going so far as these China pessimists in proclaiming the approaching doom of China Teas. Indian Teas, too, will gain in a lesser degree, by the retirement as the uncertainty was also felt occasionally on the Indian market: to say nothing of the gain which must accrue to Indian Teas by the foretold reduction of the China imports—if that does not turn out to be a case of counting one's chickens before they are hatched.

CIGAR INDUSTRY IN COLOMBO.

The launching of new industries in Ceylon, such as cotton spinning, gem mining, and cigar making, are all indications of an enterprising spirit amongst the friends of that Island worthy of all commendation. They will offer employment to a considerable number of the poorer classes of the native community, and whilst helping them to better their condition in life will be the means of circulating a good deal of money within the island, and thus indirectly contribute to the volume of trade, and the profits of traders.

The latest of these new industries is the cigar trade, and so far as the readiness with which suitable labour at a reasonable cost can be procured there is little doubt that with the good quality of Ceylon-grown tobacco an excellent article may be produced, and provided the packing of the inside of each cigar be fairly conducted, and all rubbish rigorously excluded, they may in time command a good market at very remunerative rates. So difficult is it to obtain good cigars in England at any moderate price, that a good article at a mod-rate charge would be welcomed by those smokers, whose numbers are now largely on the increase.

We are in some little doubt, however, whether the Ceylon Cigar Company may not have to reckon with a disadvantage not taken into account, the extreme humidity of the climate during at any rate, the south-west monsoon in Colombo, where the business of cigar-making is to be conducted. The extreme dampness of the Colombo atmosphere, so much lauded by the promoters of the Cotton Spinning Company, will, we fear, be detrimental to the keeping properties of cigars. An answer to this objection may be offered in the statement that for a long time to come it is expected that the entire output of the Colombo cigar factory will be disposed of on the spot, as soon as made, to local consumers and to passengers by steamers calling at the port en route for Australia, where the import duty being heavy, most smokers will carry away a box or two, of which they will break bulk, and so avoid the import duty. We venture to doubt if cigars passing into consumption immediately after making would meet with approval, a certain age being necessary to mature them. We may be mistaken in this, but it is certain that the finest cigars on the London market come from Havana, Sumatra and Jamaica, in all of which places the atmosphere is devoid of humidity. —“Ceylon Advertiser.”

DIAMOND DRILLS: WHY SHOULD ONE NOT BE GOT BY THE CEYLON GOVERNMENT?

According to the Melbourne *Age* the demand for the Government diamond drills in Victoria is so great that it is contemplated to increase the number. There are 14 drills under the control of the Mining Department, but one of these is to be permanently handed over to the Water Supply Department, in order to facilitate the extensive line of test bores put down in the arid districts for artesian supplies of water. The recent impetus given to coal prospecting has induced the Government to set apart four of its largest drills for prospecting the carboniferous areas, especially in Gippsland. In the alluvial mining centres the diamond drills are found to be most serviceable in tracing the trend of leads, and are consequently in great demand. It is found that if a series of bores are to be put down to trace the outlet of the Ballarat leads, the number of drills will have to be increased. Plans have been prepared for an improved Giant drill capable of boring to a depth of 3,000 ft. This drill will probably be employed at Ballarat in tracing the outlet of the rich leads which have been the past glory of the district. The Mining Department also has under consideration an offer from Mr. G. Lansell, of Sandhurst, to allow the Government to bore from the bottom of the 180 Mine, which is 2,640 ft. deep.

The series of bores put in from such a depth would be an experiment fraught with the deepest interest to the mining community.—*Fiji Times*, Jan. 11th.

CINCHONA AND TEA.

(From I. A. Rucker and Bencraft's Weekly Price Current.)

LONDON, Jan. 16th, 1890.

Ceylon shipments, January-December, 1889 were only 9,468,000 lb. against 12,684,000 lb. in 1888, shewing a falling off of 3,216,000 lb.

Java shipments, January-November, 1889 on the contrary were about 4,800,000 lb. against January-November shipments in 1888 of 3,994,000 lb. showing an excess of about 800,000 lb.

From India shipments were nearly 25 per cent heavier say 750,000 larger than the year before.

According to Messrs. Widenmann, Broicher and Co. about 9,500 packages of Calisaya arrived in London, against 7,810 packages the year before. We take the liberty of copying the following interesting table from Messrs. Widenmann, Broicher & Co.'s annual circular. Arrivals of Bark in London were:—

	Calisaya	Other South American	East Indian packages
1889 ...	9,552	455	54,545
1888 ...	7,810	1,028	61,549
1887 ...	7,190	2,068	60,603
1886 ...	3,979	6,547	61,541
1885 ...	2,599	2,688	55,367
1884 ...	2,826	15,070	39,818
1883 ...	2,774	51,006*	31,330

The above shews a decided increase in Calisaya, which runs rich Bark. Other South American are hardly worth discussing. In the East India and Java figures the Ceylon shortage becomes apparent. Of these figures the Java offerings have been about the same as last year, but the Indian much larger, the Ceylon much less, but the average strength of Indian is rather above that of Ceylon.

To complete the picture it must be remembered that in Holland of Java Bark 23,250 bales have been offered, against 15,196 last year.

From a package point of view we therefore take it that the offerings last year were slightly heavier than those of the previous year, the average strength of the Bark being decidedly richer. When it is remembered that the general impression in the trade is that the production of Quinine is in excess of consumption, we have an explanation at once of the low values current. When it is remembered that in one year Ceylon arrivals have fallen off 3,216,000 lb. we see a feature which if still further exaggerated might have a very important influence on values. It only remains to hope that increasing consumption will eventually land us on a higher basis altogether.

QUININE IN INDIA.—It has been directed that quinine for the Madras military requirements during 1890-91 may be obtained from the Nadavatam Factory through Mr. L. A. Lawson, the Director, Government Cinchona Plantations and Botanical Gardens, Ootacamund, on the condition that the cost (inclusive of carriage) be less than that which would be incurred by supplies from the Botanical Gardens, at Calcutta.—*Madras Mail*, Feb. 8th.

AN ENEMY OF TEA.—We have received stems of tea trees from a high district sent to us to discover a pest infesting them which can scarcely be rubbed off so long as the tree is living, but when dead, the enemy is easily separated. A reference to our entomological authority speedily brings the answer:—“Scale bug—a nasty pest.” This is not to be confounded with the “Scale or Brown Bugs (*Lecanium Coffea* of Nietner) being “quite a different species, much smaller and of the colour of the stem of the tea tree.” Our referee adds:—“I do not think it has been long observed, but I fear it is on the increase.” It might be well to try the effect of the same remedies as have been applied in the case of the coffee bug—green and black. We have only heard of isolated tea trees being affected.

* A misprint evidently for 15,006.—E.P.

THE RAT PLAGUE has not confined itself to the Laccadives. In the Nilgiris they have never been known to be as plentiful before, as they are at the present time. Field produce, especially potatoes, are reported to be seriously damaged by their ravages.—*Madras Mail*, Feb. 11th.

A PETROLEUM SYNDICATE.—It is stated that the Government have granted a concession of four square miles of land adjoining Finlay, Fleming's building in the Yeanangyoung sub-division to a syndicate consisting of Sir Lepel Griffin, Captain Aubrey Patton and Messrs. Kirby and Robert Gordon, C.E., to prospect for earth-oil.—*Indian Agriculturist*, Feb. 1st.

TOBACCO.—It has been said that the fact of the German Syndicate giving up its interests in Ceylon is not a good sign for the prospects of our tobacco-growing industry. But it is forgotten, that Messrs. Schappie & Co. retain a large interest through shares in the local Company. They have by no means sold out, or abandoned the Colony and they still look for returns upon their investments.

MINERALS IN PERAK are thus noticed in a report on the Kinta District:—

I sent some of the ore from the lode at Klian Repoh Tambun to the Curator of the Museum. This ore contained wolfram in large quantities, and, when assayed by the Curator, gave 65 per cent of wolfram and 21 per cent of oxide of tin. This was, of course a very rich piece, but I would point out that this lode is very rich indeed in ore. It contains tin and wolfram, and both in large quantities. Wolfram is taken to be one of the best indications of a strong healthy lode, and even if shipped in the ore, is worth from £30 to £45 a ton, according to quality.

I would again bring before the notice of Government the great utility of a diamond-boring machine, without which it is quite impossible to locate or form any opinion of these numerous lodes.

I have now found six distinct lodes in the Ulu Kinta mukim.

Most of these lodes are associated with copper, and they occur in limestone. It would be most useful to know what change takes place at the junction of these lodes with the granite, which is undoubtedly the next formation under the limestone. In my opinion, the copper would in all probability change into tin.

PEARLING OFF WESTERN AUSTRALIA.—A supplement to the *Government Gazette* issued yesterday states that His Excellency the Administrator has been pleased to direct that on and after that date the following Pearling Banks on the North-West Coast, which have been closed since the 15th November 1885, shall be thrown open for Pearling purposes until further notice: 1. Those off the coast between Depuch Island and Point Poissonier (those between Cape Thouin and Depuch Island were opened 14th July 1886); 2. Those lying between a North and South line running through the North-East of Dolphin Island to the Mainland; and 3. Those lying between the mouth of the Portesque and Cane Rivers, extending six miles from shore.—*W. A. Inquirer*, Jan. 10th.

NO COUNTRY would benefit so largely as India by the establishment of a National "Arbor day." In America and Australia "Arbor days" are public holidays in schools and the children attending them are expected in return for the holiday to plant at least one tree each. If every school boy in India put down a single tree per annum, in a few years we should have millions. On the Nilgiris it should be granted on the first day of the monsoon, and the superintendent of the gardens should be directed to grow suitable trees for the purpose and distribute them free, within certain limits, to all applicants. The stations and suburbs would present a very different aspect in a few years if this was a recognised indulgence.—*S. I. Observer*.

OIL OF EUCALYPTUS.—Mr. S. G. Wallace, of West End, Ootacamund, has for some time past been engaged in conducting a series of experiments with the oil of *Eucalyptus*. The oil is extracted from the *Eucalyptus Globulus*, which grows luxuriantly on the Nilgiris, and is said to possess great medicinal virtues. It is largely used in some of the hill tracts in Northern India, and is gradually coming into use in Southern India. It is specially effective in cases of rheumatism, bronchitis, &c., and is a good deodorant and disinfectant. The experiments made with it by Mr. Wallace have been attended with very considerable success, and the oil is said to have effected some marvellous cures in cases of chronic dysentery.—*Madras Mail*, Feb. 11th.

MR. D. MORRIS lectured on "The Sugar Islands" at the North London Polytechnic on Jan. 16th. The lecture was illustrated by a number of excellent views taken from photographs in the West Indies and the large audience was highly interested in them. Mr. Morris drew attention to the new era of prosperity which certainly would come to the West India islands if new blood and energy went forth to them, and if the mother country gave considerate treatment in regard to their staple industry, for, in spite of numerous other industries which have sprung up of late years to some of the islands, many of them, independent on sugar, must stand or fall with the action to be taken in regard to what was known as the bounty system.—*H. & C. Mail*

AN INTERESTING SPECIMEN of the *Coco de Mer* or double coconut of the Seychelles Islands, has been presented to the Museum of the Royal Botanic Society of London by Sir Gerald Graham, who received it from General Gordon. These nuts are a great rarity, and were first brought to the knowledge of European science by the currents of the ocean. Their mysterious origin caused them to be regarded as possessing miraculous healing virtues, and they are even said to have fetched their weight in gold. The palm which yields them grows to a great height, and is only found in the Seychelles. When General Gordon was commandant there he took a peculiar interest in the tree, perhaps because the supposed the Seychelles to be a remnant of an old continent which contained the Garden of Eden. It is well known that he located that region in the Indian Ocean, where these islands lie; not only for Biblical but scientific reasons. Other specimens of the tree, including nick-nacks made from its prettily striped wood, were presented by Miss Gordon to the botanical museum at Kew Gardens, where they are on view.—*Globe*.

LIBERIAN Coffee Company in JOHORE.—Liberian coffee must be well thought of in the Straits, to judge by this extract from a Prospectus just issued:—

The Company is formed to take over as a going concern from the 1st February next, the estates of "Castlewood" and "Wayfoong," comprising respectively 1,700 acres and 300 acres of fine undulating land, of which a fair proportion is virgin forest. The estates are situated about seven miles from Johore Town, and are easy of access by road or water. Cargo boats of large size can be brought up close to the Manager's house at Castlewood, taking produce to Singapore at a very small cost. The land is let on a lease of 999 years, paying 10 shillings an acre for the first crop only, and an ad valorem export duty of two and a half per cent. 182 acres are planted with Liberian coffee from four to seven years old, the yield from which for 1889 has been 700 piculs of cleaned coffee. The price to be paid to the Vendor is \$50,000 in cash and \$40,000 in deferred shares. The valuation at 90,000 dollars or 180,000 rupees say, we consider as high as anything in Ceylon in the palmy day of coffee.

CEYLON GEMMING SYNDICATES AND COMPANIES.

When we penned our remarks in a former issue on "Sapphire Syndicates," we had no idea that the caution we then gave to intending investors in this new direction of gemming industry would so soon be needed. Commenting on what has quite recently taken place, a London financial journal says:—"Within a brief period we have seen the prospectuses of three Ceylon Gemming Syndicates and one Gem Mining Company in connection with that island. The Syndicates in question, with the modesty natural to those who are desirous of not misleading intending subscribers, declare their intention to obtain the most reliable information possible touching the gem yielding lands of certain districts in Ceylon, before venturing to convert their preliminary projects into regularly constituted companies, and for this wise precaution they deserve our commendation. One of these bodies has gone so far as to despatch to the island a gem expert, formerly on the exploring staff of the Ruby Mining Company of Burma, for the purpose of ascertaining the resources of Ceylon in regard to sapphires, rubies and catseyes; the others await advices from persons on the spot possessed of gemming experience. But with regard to the Company which has asked the public to subscribe £100,000, a very unfavourable opinion has been expressed by those who are well acquainted with the properties to be acquired. We shall be pleased to know, and our columns are open for any explanation on this subject which may be of interest to investors, whether it is a fact that the areas to be leased or bought are worn out coffee estates belonging, in fact, to those who have reported favourably on them?"

The writer of the above labours under the impression that "worn out coffee estates" cannot be rich in gems, which is by no means the case. The further remarks on this subject are rather more to the purpose:—"Why should first-class engineers and costly machinery be sent out in the first instance, till it has been proved whether gems exist in these properties or not? For it must be remembered that the Sinhalese Coolies, using crowbars and native hoes, with no other adjuncts than washing baskets and buckets of water, would soon remove the few feet of surface which overlies the gravel and clay in which the gems are embedded. If deposits are thus found, and if they retain their richness, or increase in value as depth is attained, then we admit that first-class engineers and the best mining machinery, however costly, should be sent out. But until it is clearly ascertained that the rich deposits of gems exist in the estates acquired by the Company, we think that its resources should be husbanded with the most jealous economy."

NOTE.—We understand that the directors of the "Ceylon Gemming and Mining Company" do not look to gemming alone, but intend that their mining operations, in which the services of first-class engineers will be required, shall be in the direction of plumbago mines which exist to a large extent on their properties. They have reports showing the existence of thousands of tons of the finest silvery plumbago for which that district has long been noted.—"Ceylon Advertiser."

THE RICE MERCHANTS and rice millers of Rangoon are not happy. It seems the Burman has discovered a system of increasing the weight of his paddy by wetting it with salt water, which has not the immediate deleterious effect on the grain that fresh water has. The merchants have asked for special legislation on the subject. After consulting district officers the Financial Commissioner has replied that Government is not prepared to specially legislate to protect the merchants or to give them a system of registering Burmese paddy boats, which would cause considerable expense.—*Madras Mail*,

PLANTING: LONDON-CEYLON NOTES.

A good deal of progress is expected to be made during the year just coming, in the development of the Ceylon tea trade in the Canadian Dominion, where a number of agencies are already at work.

Whereas in 1880 the total value of the tea crop in Ceylon was only about £5,000, in 1888 it reached the sum of 1,155,095, and in the first nine months of the present year it was worth £1,170,262. The English evidently consume more tea than any other people. The Germans consume 1 lb. to our 53 lb., and the French 1 lb. for our 159 lb. Indeed, while we and our Colonies use from 4½ lb. to 7½ lb. per head, and the United States 1¼ lb., the only non-Anglo-saxon people who exceed 1 lb. are the Dutch. In 1885, out of every 100 lb. of tea consumed in Great Britain, 37 were Indian, 62 Chinese, and only one the produce of Ceylon. Two years later the figures were 45 Indian, 49 Chinese, and 6 Ceylon. In the first three quarters of 1889 the figures were—50 Indian, 84 Chinese, and 16 Ceylon.

A Ramie Company, with a capital of a million dollars, has just been started in Philadelphia to engage in the cultivation and preparation of Ramie, and build machines for its decortication and for mills to bleach and spin the fibre. It promises to be a grand success. Ramie is said to be an excellent fibre, better, stronger, and finer than cotton or wool, and about equal to silk in lustre.

A most useful invention is a new bottle stopper, consisting of an acorn-shaped piece of hard rubber, in which runs a screw of non-corrosive metal. At its upper end is a little swivel, and at its lower end a band of pure soft rubber. Turning the swivel downwards swells the rubber and closes the bottle tight, whilst the reverse motion loosens and allows the stopper to be easily withdrawn.

The fiscal system of Brazil requires to be thoroughly revised and purified in every department. A great number of national and provincial taxes should be abolished. Brazilian coffee is exported, handicapped by a duty of 15 per cent. In the city of Rio de Janeiro the produce of a number of local taxes is absurdly insignificant. In the province of Minas Geraes the report of the Chancellor of the Exchequer yearly reveals a lamentable state of fiscal affairs. In 1887, one division of the receipts consisted of 6 per cent duties on twenty-eight articles, of which fourteen yielded, for the whole province, £20. One article gave a shilling. The administration of several of the provincial custom houses cost several times their revenue. In 1887 a provincial treasurer reported that one special new tax of the previous year had "killed the industry."—"Ceylon Advertiser."

TOBACCO CURING IN SOUTHERN INDIA.

Letter from H. Caine, Esq., Tobacco Expert, to the Secretary to the Commissioner of Revenue Settlement Land Records and Agriculture, dated Madras, 7th May 1889, No. 174:—"I have the honor to submit report of the results of my visits of inspection to the Godavari lunkahs. I left Madras on the 27th March 1889 and arrived in Cocanada on the 29th. I made arrangements about a boat to take me up to the canal to Rajahmundry. Mr. Happell, the Collector of Cocanada, was away, so I was unable to see him; the Assistant Collector, however, gave me what information I wanted. I left Cocanada on the night of the 31st March and arrived at Dowlaishweram on the 1st April; from thence I went by road to Rajahmundry, head-quarters of the Godavari district. On arriving at Rajahmundry I found the Sub-Collector was away. I saw the Tahsildar, who gave me the names of the best lunkahs to visit, and on arrival of the Sub-Collector on the 5th April, I started on the following morning and inspected several lunkahs, notably the Mullaka lunkahs, distance eight miles from Rajahmundry. During the day I visited twelve curing sheds, and, with the exception of the tobacco grown on the "new lunkahs," there was no difference to be noticed in the size, texture or general appearance of the leaf. The soil on the "new lunkahs" is mostly silt and but little sand; the tobacco grown here was much cleaner, texture and

color and flavor same as on the other lunkahs. "Bodu" was not very destructive this season on any of the lunkahs owing to scarcity of moisture, the Godavari river not having risen to its usual height on account of the deficient rainfall. My report on the "bodü" I have already submitted in my letter No. 158, dated 13th April. In the above-mentioned lunkahs nearly the whole tobacco crop had been harvested, and I was only able to see a small quantity of the first cuttings; the sheds were mostly filled with the second harvest; however, I was enabled to purchase fifty green plants of the first growth, and during my stay in Rajahmundry I managed to cure the leaf well enough to perceive that great improvement can be obtained by introducing the same method of shed curing as pursued by the Government experiment in the Madura and Dindigul districts. During the time I stayed at Rajahmundry, I visited the Nagu and Kurrieba lunkahs, 8 miles from the town, lower down the river Godavari; these lunkahs were not flooded during the past season and the crop of tobacco was poor, texture and color of the leaf the same as on the other lunkahs. The tobacco on all the lunkahs which I inspected above the anicut is very much the same in color, texture and flavor, the only real difference being in the size of the plants; in the richer lunkahs the tobacco crop is larger and heavier. I was unable to carry camp with me owing to bad roads, the season being so far advanced, the transport of tents, &c., across miles and miles of sandy lunkahs would have been impracticable; there being no canals above the anicut, I could not travel in this way by boat or by the river either, as the latter was drying up, and near the lunkahs the difficulty of transporting tents across the sand would have been insurmountable. The method of curing adopted is the same in all the lunkahs; the mistake lies in keeping the tobacco, whilst in its green stage, too much exposed to sun and light; hence too rapid evaporation and consequent drying of the sap, resulting in the colors being mottled green, yellow and light red. During the latter part of April, I arranged for a house-boat to take me down the canal to inspect some of the lunkahs below the anicut, so I packed up my tobacco and accordingly left Rajahmundry on Wednesday and travelled down the Amalapuram canal. I halted for the night near the bank, and the following morning I travelled across the country to the Gowtami Godavari and inspected ten sheds on the Bhaluguvani and other lunkahs. The ryots were much taken with the color and appearance of the tobacco which I had cured and wished to know how it was done. The Bhaduguvani lunkah is, I think, the best one on the Godavari; the tobacco crops are said to be very fine; this year, however, the results were not so good as usual. I was much taken with the tobacco on the Bhaduguvani lunkah, the texture of the leaves was good with plenty of gum; nearly all the best tobacco had been packed, and most of the sheds were empty. I managed to obtain some samples of yellow tobacco which I have brought down to Madras with me. Judging from what I have seen of this year's crop, I feel persuaded that the only method of curing suitable tobacco for the European market would be for mahogany colored cavendish wrappers and also yellow tobacco (bright smokers); these two sorts would easily find a sale in England. For cavendish wrappers, a long and large leaf would be requisite; from different accounts, large tobacco is usually grown on the lunkahs in favorable seasons. For pipe tobacco (bright smokers) a medium-sized leaf is most suitable. To obtain cavendish wrappers of the proper color, however, a moist temperature is preferable, and in the town of Cocanada itself on the canal bank the leaf would cure a much darker and more valuable color than what would be the result if the tobacco were cured on the lunkahs. Again, the pipe tobacco would cure better in a dry quick heat and would cure well on the lunkahs. I should therefore respectfully suggest that an experiment be tried next year; there can hardly be any doubt but that it would succeed, and if it does there is one firm I know in Cocanada—probably many others—who would willingly take the tobacco curing up.

I should propose that the tobacco be estimated and brought from the ryot in its green state when ripe and cured up by me in three different ways, producing different results, viz:—I. A small experiment in curing by charcoal (1st-grade bright smokers). II. An experiment in shed curing (bright smokers, 2nd grade). III. An experiment in shed curing cavendish mahogany wrappers (to be conducted near the sea). In the latter case the green leaf could be easily transported in a house-boat and removed to curing shed on arrival at Cocanada. A single year's trial would be sufficient to convince the brokers in England that good pipe tobacco can be grown in India in a cheaper way and of a quality good enough to compete with Virginia tobacco on its own merits. The bright smokers tobacco, samples of which I have brought with me, would be valued at not less than 8d. per pound in England. First-grade bright would fetch 8d. to 1s. per pound and good cavendish wrappers (long red) from 8d. upwards. If properly conducted, there ought to be a big future for lunkah pipe and cavendish tobacco. Judging from the samples of cigar tobacco tested and smoked by me, I would not advise cigar tobacco being taken up as an article of export to Europe from the lunkahs; no doubt a different style of curing and judicious fermenting would decidedly improve the quality for this country, yet pipe tobacco and cavendish wrappers would prove an infinitely more profitable speculation for export. The quality of the present lunkah cigars is execrable, being strong, rank hot and saltish to the taste, besides gritty and full of sand; this would render it unfit for the European market. If Government meet my views on the matter and propose that I should be deputed to Cocanada next season, I respectfully beg to point out that I should have to be at the lunkahs in February, and could not therefore undertake the whole management of curing in the Dindigul district. Suppose the two curing sheds at Vedesandur were rented out to the ryots and I were to superintend the curing of their tobacco till I left in February 1890, the ryots themselves could then manage the rest, viz., taking down and bulking the leaf; they have all seen how well the first experiment has answered, and would no doubt gladly cure their own tobacco in the sheds if I were on the spot to assist them at the commencement. My engagement with the Madras Government is so short that I want to do everything in my power to push the tobacco experiments forward. I am of a decided opinion that the tobacco in Godavari lunkahs should not be neglected.

Reference on the above, dated 23rd May 1889.

Before disposing of these papers, the Board requested Mr. Caine to explain how he proposes to overcome the character of the lunkah tobacco as to its being "gritty and full of sand," as these very characteristics have so far been a fatal bar to the competition of Indian tobacco in the European market as a pipe tobacco, the presence of dust and grit unduly weighting tobacco liable to heavy duties.

Read—the following letter from H. Caine, Esq. Tobacco Expert, to the Secretary to the Commissioner of Revenue Settlement, Land Records and Agriculture, dated Vedesandur, 25th May 1889, No. 189:—

I have the honor to acknowledge receipt of letter No. 174, dated 7th instant. I have the honor to state that the amount of gritty sand which abounds in the lunkah tobacco, is due to the slovenly and careless custom prevalent amongst the ryots in allowing the green tobacco, after it is cut, to remain two to three days heaped up on the ground; every day these heaps are opened and the tobacco spread apart. It may be easily understood what an amount of sand the leaves gather up during each of these operations; I should decidedly remedy this by not permitting the tobacco plants to touch the ground, but have the plants passed to the hanger as soon after they are cut as possible, or else have some material, grass or straw, placed on the ground as a protection.

2. The native curing sheds are built with only two sides, both the northern and southern ends remain open, thus enabling dust and sand to blow in if any high winds should prevail during the curing. It is my opinion that

the sand does not adhere to the leaves whilst the plant is growing, but is brought about by the indifference of the ryot; or probably they prefer the sand, as it adds weight to their produce, in the same way the cotton cultivators have acted. On the new lunkah, I noticed, and have also mentioned the circumstance in my reports, that the tobacco grown here was free from dust and sand, because the soil was composed of pure silt, there being no sand in the neighbourhood. In some parts of Bengal the dust* does undoubtedly adhere to the tobacco plants whilst they are growing, as the west winds set in earlier.

3. The proper curing sheds which should be erected would be closed on all sides; this would entirely avoid the sand during high winds. I myself am perfectly aware of the importance of producing clear pipe tobacco for the English market, and should never suggest experiments in places where the dirt could not possibly be avoided. At the Pusa factory it was principally on account of the dust that the tobacco realized such insignificant prices in the English market.

JAMAICA COGWOOD.

(*Zizyphus Chloroxylon*, Oliv.)

(From the *Kew Bulletin of Miscellaneous Information*.)

The cogwood in Jamaica has long been known as one of the most valuable timber trees in the Island. In the early days of sugar and coffee planting cogwood was everywhere in demand for framing for mills and for cog-wheels. It was also known as being very durable in water. It was a tough, hard, and ponderous wood, and sought to be used on all occasions where strength and durability were required. It is probable, owing to the valuable character of the wood, that trees of large size became comparatively scarce, and at the present time such trees are only to be found in remote districts beyond the reach of roads and railways. Our interest at present is not so much connected with the value of cogwood as a timber tree but with its botanical determination. Although known for so long a period it is remarkable that until now the flowers and fruit of Jamaica cogwood had not been received in this country, consequently the position of the plant in botanical classification had been in doubt. * *

From the material received from Mr. Fawcett, Professor Oliver has determined the cogwood to be a species of *Zizyphus*, a genus not previously recorded from Jamaica. *Zizyphus* is the Jujube or Lotus genus of *Rhamnea*, and the fruits of several species, such as *Z. vulgaris* and *Z. Jujuba*, have an agreeable flavour, and are commonly eaten. A description of cogwood with a plate has been prepared for the *Icones Plantarum*, and by the courtesy of the Bentham Trustees a reproduction of the latter is included here with the description:—

Zizyphus Chloroxylon, Oliver (in Hook. Ic. Plant. Pl. 1862, *med.*). An unarmed tree, with wide-spreading branches. Leaves alternate, ovate or ovate-elliptical, pointed, triple-nerved, the nerves extending to the apex, 4 to 7 inches long, 1½–4 inches wide, quite entire, smooth, nerves beneath prominent, petioles ½–¾ inch long.

Cymes many flowered, corymbose, the peduncle short, pedicels equalling the flowers. Flower-buds rusty-puberulous. Calyx lobes five, spreading, ovate-deltoid, bifoveolate, fleshy, conspicuously keeled on the inner face. Petals none. Filaments as long as the anther. Style three lobed at the top. Fruit subglobose, smooth, one seeded, 8 to 10 lines in diameter. Pericarp crustaceous. Seeds roundish, cotyledons plano-convex. Radicle inferior.—*Ceanothus Chloroxylon*, Nees Syst. Laur. p. 66. *Laurus Chloroxylon*, L. Sp. Pl. Ed. ii., p. 528.—Jamaica in the interior mountains, moderately common.

There is only one small specimen of the Jamaica cogwood in the Kew Museum, and this was obtained from the Paris Exhibition, 1855. It is labelled the "best wood for mill framing and cogwheels, very durable in water." In this specimen the heart wood is

developed only to a small extent, occupying in fact only the central core about 3 inches in diameter out of a total diameter of about 9 inches. To procure serviceable heart wood of the characteristic colour, texture, and weight, it is probable the trees must be allowed to attain considerable age and size. The value of the timber is unquestioned, and in any system for the conservation of forests, and replanting denuded areas that may be adopted in Jamaica, the cogwood will no doubt receive, as it deserves, special consideration. So far as can be gathered this valuable tree is entirely confined to Jamaica.

[It ought to be introduced into Ceylon.—Ed. T. A.]

COCONUT COIR FROM LAGOS.

As may be gathered from the reports published in the *Kew Bulletin* (1888, p. 149, and 1889, p. 69), Governor Moloney has organised very extensive nurseries in different parts of the Colony of Lagos for the purpose of extending the cultivation of the coconut palm. Plantations consisting of 30,000 trees have already been established by the Government, whilst seedlings in large quantities are supplied at low rates to private persons with the view of making the industry as general as possible. In this work the recently established Botanic Station is actively engaged, as also the Government organisations attached to the Commissionerships of the Eastern and Western Districts, and of Palma. With the view of utilising to the best advantage the produce of these coconut plantations, when in full bearing, Governor Moloney has recently prepared experimentally some samples of coconut fibre so that an opinion might be obtained as to its value in this country. This West African coir was sent to Kew, and very interesting particulars respecting it are contained in the following correspondence:—

COLONIAL OFFICE TO ROYAL GARDENS, KEW.

Downing Street, 2nd February 1889.

SIR,—I am directed by Lord Knutsford to transmit to you a copy of a despatch which he has received from the Governor of Lagos reporting that he had despatched a bale of [coconut] coir to Kew.

2. His Lordship will be much obliged if you will kindly furnish him with your opinion on the specimen forwarded.

I am, &c.

(Signed) R. H. MEADE.

The Director, Royal Gardens, Kew.

[Enclosure]

GOVERNOR MOLONEY TO LORD KNUTSFORD.

Government House, Lagos, 23rd December 1888.

MY LORD,—At the Colonial Exhibition of 1886 I was given to understand that the natural colour of Lagos coir had, in the opinion of brush and mat manufacturers (I may mention Messrs. Treloar, of Ludgate Hill), a special advantage which should command for it a ready demand and a comparatively high price, if it could be put regularly and in sufficient quantity on the English markets.

2. Accordingly, and in anticipation of the later development of a local manufacture for export of coconut oil, for which I entertain the opinion that the present annual crop of fruit offers a sufficient encouragement, I have had prepared by prison labour in the gaol of Lagos a bale of coir weighing 42 lb.

3. This return represents the yield of 400 coconuts, the average present price of which is at the rate of 2s. 6d. per hundred.

4. The bale has been addressed to the Royal Gardens, Kew, and sent through the Crown Agents for the Colonies.

5. It is now my duty to request that your Lordship will be good enough to invite the co-operation of the Director of the Royal Gardens and obtain an authoritative opinion on the specimen forwarded.

I have, &c.

(Signed) ALFRED MOLONEY.

The Right Hon. Lord Knutsford, G.C.M.G., &c. &c. &c.

* Not sand.

ROYAL GARDENS, KEW, to COLONIAL OFFICE.

Royal Gardens, Kew, 21st February 1889.

SIR,—I am desired by Mr. Thiselton Dyer to acknowledge the receipt of your letter of the 2nd instant, forwarding a copy of a despatch from the Governor of Lagos on the subject of a specimen of coconut coir which he had forwarded to Kew for an opinion as to its merits.

2. The specimen, consisting of a bale weighing 42 pounds, was duly received from the Crown Agents on the 11th ultimo. Samples were prepared and submitted to respectable brokers and dealers in the city, with a request that they would report upon the value of Lagos coir as compared with other coirs now in the London market.

3. The result of the inquiry is contained in the accompanying papers. It would appear in the first place that it is necessary to separate coir fibre, as yielded by the cocout, into two classes, namely, "bristle" fibre and "mat" fibre. The former is usually sold at about 30% per ton, and the latter at about 10% per ton.

4. The sample from Lagos contained these two fibres mixed together, and hence it was not presented in a state suitable for sale in this country. It is evident that Lagos fibre possesses no particular merit on account of its colour, but on the other hand, in Messrs. Harrison and Johnson's Report, it is stated to be "of very good length, which increases its value."

5. Although these reports are not so encouraging as Captain Moloney was led to suppose from the specimens exhibited at the late Colonial and Indian Exhibition, they furnish useful hints as regards the character of coir fibre necessary to command ready sale in this country.

6. With the view of further assisting in this direction, Mr. Thiselton Dyer has caused the specimens of Ceylon "Bristle" and Ceylon "mat," forwarded by Messrs. Ide and Christie, to be sent direct to Captain Moloney as samples of coir fibres, which are acceptable to the London buyers. Other samples of fibre are enclosed in the parcel for Captain Moloney, including "brush" fibre, and "rough stuffing" fibre, prepared by Messrs. Toye and Bromley from the crude Lagos coir.—I am, &c.,

(Signed) D. MORRIS.

The Hon. R. H. Meade, C.B.

[Enclosure No. 1.]

MESSRS. IDE AND CHRISTIE to ROYAL GARDENS, KEW.

72, Mark Lane, London, E.C., 7th February 1889.

SIR,—We are duly favoured with Mr. Jackson's letter of the 5th inst., and samples of coir from Lagos. These contain soft, half-prepared "bristle" fibre, used in the manufacture of brushes, mixed with short or "mat" fibre. Such a mixture is unfortunate, and detracts from the value of the samples, as the two kinds, being used for different purposes, have to be separated. In the Ceylon coir they are always kept apart, and for your guidance we send you specimens of Ceylon bristle, value 30% per ton, and Ceylon mat, value 10%.

There is nothing either in the colour or other character of the Lagos fibre which would justify the expectation of its commanding a ready demand and high price, as the Governor of Lagos has been apparently led to believe. On the contrary, we value the "bristle" portion of your samples at 15%, and the "mat" portion at 9% to 10% per ton.—We are, &c.,

(Signed) IDE AND CHRISTIE.

D. Morris, Esq., M. A., F. L. S.

[Enclosure No. 2.]

MESSRS. HARRISON AND JOHNSON to ROYAL GARDENS, KEW.

4, Catherine Court, Trinity Square, London, E.C.,

7th February 1889.

SIR,—We are in receipt of your favour of the 5th instant, and also the sample. The coir fibre you send is mixed half-prepared brush and mat fibre. The former if separated would no doubt find buyers at about 15% per ton, and the mat fibre would sell freely at 9% to 10% per ton.

There is one sample consisting entirely of mat fibre; this is clean and long and would sell well at

about 11% to 12% per ton. If the brush fibre were properly combed out like sample we have sent you by post, it would readily fetch 28% to 32% per ton present market value. The samples of fibre you send are of very good length which increases the value.

We would suggest that a small sample shipment be made, you would then get a good idea of the value. It would be no use sending any fibre unless the mat and brush were kept separate.

If in future we can be of any help to you or to the Governor of Lagos in bringing this article before the trade we should be pleased if you would make use of us.—We are, &c.,

(Signed) HARRISON AND JOHNSON.

[Enclosure No. 3.]

MESSRS. TRELOAR AND SONS to ROYAL GARDENS, KEW.

68, 69, and 70, Ludgate Hill, E.C.,

9th February 1889.

SIR,—We are in receipt of your letter of the 5th and of the sample of Lagos coir. In our opinion this is badly cleaned or dressed, and not so good for brush-making as the usual sort. It certainly has no special advantages for mat-making, and is not in our opinion calculated to command a high price here. We have seen better fibre sold at public auction for 22s. per cwt. in London.—We are, &c.,

(Signed) TRELOAR AND SONS.

[Enclosure No. 4.]

MESSRS. TOYE AND BROMLEY to ROYAL GARDENS, KEW.

116, Fenchurch Street, London, E.C.,

19th February 1889.

SIR,—We confirm our letter of the 11th inst. and now beg to hand you our report on the fibre samples you sent. We trust this will give you the information desired. Should you require any other point answered we shall be happy to do so.—We are, &c.,

(Signed) TOYE AND BROMLEY.

Report.

This fibre would find a ready sale here both for brush and mat making purposes, but the two sorts should be kept separate. For brush-making the long fibre can only be used and should be kept straight, and tied in small bundles and then made up in bales weighing about 1 cwt. or 2 cwt. each. The other sort for mat-making should be towelled and packed up into bales. Practically speaking the mat fibre is the combings or short from the brush fibre. There is also in the sample sent us a stuffing of rough fibre in each of the small bundles; this should be avoided as it deteriorates the value considerably; but if this stuffing was separately packed it would also sell here. We consider the value of the three sorts, if made up in the way we have described, would be based on the present value of fibre as follows:—

Sample.

No. 1. Brush fibre at 29% to 31% per ton.

No. 2. Mat fibre at 18% to 19% per ton.

No. 3. Rough stuffing sort at 10% to 11% per ton.

We return a sample of each quality to show more clearly our meaning. The brush fibre, we suggest, should be tied up about the size of our sample No. 1. You will notice that we have taken your sample as received, and dressed it into the above three sorts, which your friends will find far more advantageous than sending it in the rough condition.

(Signed) TOYE AND BROMLEY.

PATCHOULI.

(*Pogostemon Patchouli*, var. *suavis*.)

Patchouli has already been the subject of notice in the *Kew Bulletin* (1888, p. 71 and p. 133). An interesting article on the *Cultivation and Curing of Patchouli and its Adulteration* has lately been contributed to the *Journal* of the Agricultural and Horticultural Society of India by Mr. L. Wray, junior, Curator of the Government Museum, Perak. As the information contained in this article may not be readily accessible in this country and in the Colonies, it has been thought desir-

able to reproduce it in the *Kew Bulletin*.—

The plant yielding the perfume known as patchouli is usually stated to be indigenous to the Malayan Peninsula, but this seems to be doubtful, as there appears to be no evidence that it has been met with in the jungle, except in place where it could be clearly traced to some old cultivation.

It is grown and much esteemed by the aboriginal tribes of Perak and Pallang, and this should be borne in mind when cases of its being found in out-of-the-way places are brought forward in support of its being a native of the Peninsula. I have met with it at an altitude of nearly 5,000 feet amongst the Sakais of the mountains at the source of the Pallang River, far away from any Malayan villages, also among the same people in the Bernam, Batang Padang, and Kinta Districts of Perak, and among the Semangs in Upper Perak and Selama.

The leaves are made into garlands and worn round the waist by the women, and bunches of them are often stuck into their bamboo earrings. I have also seen them mixed with other leaves and flowers and formed into ornamental bunches which are hung up and used in some sort of demon worship or propitiation.

The Sakais of Batang Padang call the plant *Boon kalif*; and, as this is not a corruption or derivation of the Malayan name, it may point to its being known to them prior to their coming in contact with the Malays. The latter people call it *Poko nilam*. The word *nilam* means sapphire, therefore the translation would be sapphire plant.

Patchouli is a very shy flowerer, so much so that by the natives it is said never to flower; and Mr. Hardouin told me that though he had grown and bought it for the last 30 years, he had never seen or heard of such a thing as a flower or fruit. Mr. N. Cantley, in "Notes on Economic Plants," says: "Plants raised from seed are reported to grow well, but to have no scent, but retain it when produced from cuttings. I have not been able to verify these statements, but it is well known that plants do sometimes play tricks of this kind—sandal-wood frequently." If this report was obtained from naive sources it probably only represents another way of saying that the plant hardly ever bears seed.

Many similar sayings exist in regard to other occurrences which are either very rare or do not occur at all. For instance, hidden treasure is said to be found beneath a flowering plant of lemon grass; and the nest of a certain bird (which does not build one) will render the finder of it invisible.

CULTIVATION.

The cultivation of patchouli is carried on almost exclusively by the Chinese in the Straits Settlements. They do not grow it on a large scale, but a man will plant a patch of perhaps half an acre, or an acre at a time.

The land is trenched and thrown up into long beds either 4 feet or 18 inches wide. The former width will take two rows of plants, and the latter only one. The plants are put 2 feet apart along the rows.

The planting should be done in the wet season, and the cuttings, which are about a foot long, require careful shading with leaves until rooted, or they will get withered and die, the plant being a delicate one, and very susceptible to the heat of the sun.

The first cutting of the crop is made in about six months after planting, by which time the patchouli will have reached a height of 2 to 3 feet, and two other cuttings are made from the same plants at intervals of about six months. At the end of this time the old roots are dug up, the land re-trenched and manured and fresh cuttings planted.

I could get no reliable information as to the yield per acre, nor the cost of cultivation, but it must be rather high, as the land has to be thrown up into beds, manured and carefully weeded, and the cuttings shaded, and in the event of dry weather setting in before they are rooted, they have to be watered until established.

Both flat and hill lands are suitable to its cultivation, and it seems to flourish best under slight shade, but probably the production of oil is less in that grown under shade than in that grown out in the sun, though the yield of leaf would be greater.

I was told by a Chinese merchant, a dealer in patchouli, that it is often planted on new land between coffee, nutmegs, and other permanent crops, and that it pays all the expenses of clearing and planting, leaving the permanent crops as clear profit.

Of natural enemies patchouli seems to have a fair share. One was described to me as a beetle, but as the young leaves which it is said to attack are dwarfed and deformed rather than eaten, I am inclined to think it is a bug. The older leaves are very much attacked by some insects, probably caterpillars and some of the grasshoppers.

CURING AND PRICES.

The plants are cut down near the ground when they have reached a sufficient size, one stalk only being left to each bush. The patchouli is then laid out in the sun to dry in the daytime, and put under cover at night and on the approach of rain.

The time required to dry it varies with the weather, taking from four days to a week. When thoroughly dry it is done up into bales, and sold either to dealers in the leaves or to the distillers. In this state it fetches about \$8 per pikul of 133½ pounds.

The dealers cut it up and separate a great quantity of the larger stalks, and, according to its freedom from these, it is classed as 1st, 2nd, or 3rd quality. The best consists of leaves only, and is valued at \$30 to \$32 per pikul; but owing to the labour involved, this quality hardly pays to prepare. The second quality is composed of leaves and young shoots with little of the heavier stalk, and ranges in price from \$17 to \$20 per pikul. The third quality contains less leaf and more stalk, and fetches about \$14 per pikul.

The best quality of all would be produced by picking from the plants the leaves and tops of the young shoots, and drying these in the shade, but it is doubtful if it would pay. Prepared in this way 36 lb. of green leaves produce 10 lb. of dried patchouli. The percentage of essential oil in shade-dried leaves is, as might be expected, higher than in those which have been exposed for many hours to the full heat of a tropical sun, which in this latitude often goes over 120° F.

ADULTERATION.

Large quantities of the leaves of a plant known by the Malayan name of *Ruku* are often mixed with patchouli. The botanical name of his plant *Ocimum Basilicum*, L., var. *pilosum*, Benth.

I was told by Mr. Hardouin (the principal distiller of patchouli oil in the States) that recently a Chinaman bought the whole of the *Ruku* growing wild in a coconut plantation in Province Wellesley, and 700 pikuls of the dried herb were collected and taken to Penang, to be used for the adulteration of the more valuable patchouli. Mr. Hardouin says he always prefers to buy the plant just as it is cut, as then it is easy to see if it is adulterated or not, but if the leaves are bought it is very hard to detect the imposition.

The *Ruku* leaves are rather whiter and the stalks smaller and rounder. Seed vessels are often also mixed with them. The smell of the two herbs is quite different, but if the samples has been baled for some time, this would be imperceptible except as communicating a twang to the general odour of the sample.

The leaves of another plant are also often mixed with patchouli. This plant is called *perpulut* by the Malays, and is known botanically as *Urena lobata*. The leaves are when dried much like those of the herb it is used to adulterate, but, unlike it, they are scentless. *Perpulut* is a very common weed all over the Straits Settlements, and is to be had in any quantity for the trouble of collecting it.

MANUFACTURE OF THE OIL.

The dried patchouli is put into a large copper cylinder fitted with a perforated false bottom and mounted on trunnions. Through one of these steam enters from a boiler and is conducted by a tube beneath the false bottom. The remaining trunnion is also hollow, and the steam, after passing through the leaves, passes out by it and into a worm immersed in a tube

of water in the ordinary way. The pressure of steam employed is about 10 pounds per square inch, but it varies with the size of the worm and the temperature of the water used to cool it.

One pikul of the dried patchouli, just as it is cut, yields from 24 to 30 ounces of essential oil, and a sample free from the heavier stalks yields about double that amount.

Mr. Hardouin says, that by an ordinary still not more than one-half of the oil can be extracted, the temperature I presume not being high enough to volatilize the whole of it.

He also says that the green leaves yield little or no oil, and therefore it is necessary that they be dried before being subjected to the process of distillation.

The oil is of two distinct varieties, the one being sage green, and the other the colour of medium coloured sherry.

Mr. Hardouin informed me that the green oil is produced from young leaves, and the golden-brown from old leaves, but I am inclined to think that there is a little doubt about this, and that soil and shade have more to do with the colour of the oil than the age of the leaves.

Sometimes the one colour is in greater demand than the other, but the prices are the same for both. At present the price in Penang is about 50 cts. per ounce.

Whether the oil is adulterated or not I have been unable to find out, but the changes are largely in favor of it if it passes through the hands of the Chinese merchants. I obtained two samples of the oil direct from the distiller, and find they are limpid and quite fluid at ordinary temperatures, but at 4°C F. they become rather thicker, but remain bright and clear.

The golden-brown oil has a specific gravity of .9580 at 85° F., and the green oil a specific gravity of .9578 at the same temperature.

The spectrum exhibited by the golden-brown oil is not crossed by any absorption bands, and is, therefore, not of much use in detecting admixture of foreign oils. The red, yellow, and green light, as far as the *b* line, is transmitted with full intensity; but the blue-green from *b* to *F* is much absorbed, and beyond the latter line all is complete darkness. The limits of this spectrum in wave lengths are 7140 to 4165, the oil being contained in a tube 6 inch in diameter, both daylight and lamplight being used with the same results.

The green oil gives a spectrum of full intensity from the *c* line midway between the *b* and *F* lines, from which point it shades off gradually and disappears a little before the *h* line is reached. At the red end it extends beyond the *c* line, but with reduced intensity as far as to between the *A* and *a* lines. In wave lengths the limits of this spectrum are 7390 to 4130 in daylight. Lamplight gives a greater extension towards the red end, but much less in the violet.

I have seen oil that has been kept for 10 years in a bottle with a loose stopper, which had become of a dark-brown colour and of a syrupy consistency, but it seems probable that it would not undergo this change if kept in a tight stoppered or corked bottle. The scent of this old oil, however, was little inferior to fresh, though not quite so powerful. This bears out the statement in *Ure's Dictionary of Arts*, that "the essential oil of patchouli is one of the least volatile of any known, hence it is one of the most persistent of perfumes from plants."

In the same work it is stated that if the plant be distilled, after it has been gathered several years, more than half the product will assume a crystallisable form far less fragrant than the newer fluid essential oil, and would probably be quite odourless if repeatedly crystallised from alcohol. The crystals of patchouli are rhombic with pyramidal summits; chemically they resemble camphor in composition. When the fluid essential oil of patchouli is submitted to fractional distillation, there comes at the highest temperature a peculiar blue body, termed by *Picasse Azulene*, "resembling the blue in the essential oil of wild camomile; it requires, however, further examination."

"All effects, such as loss of appetite and sleep, nervous attacks, &c., have been ascribed to the excessive employment of patchouli as a perfume." (*Lindley's Treasury of Botany*.) But as one of its great

uses is to mix with the stuffing of beds and pillows, under the idea that it is inimical to vermin, this can scarcely be the case. This same property of keeping-off insects caused it to be used to pack with Indian shawls and so led to its introduction into Europe.

In connexion with this it should be mentioned that I have distilled a quantity of the *Ruku* leaves (one of the plants used to mix with patchouli), and have obtained a very dark green viscous oil, smelling strongly of the plant.

The amount of oil is not great, and it is unlikely to have any value of its own, for the scent of it is not altogether pleasant.

MARKET.

Mr. N. Cantley, Superintendent of the Botanical Gardens, Singapore, in a paper entitled, "Notes on Economic Plants" in the *Journal* of the Straits Branch of the Royal Asiatic Society, says, "Plants of patchouli have been in demand for experimental planting, and a good number have been supplied. Picked leaves are now selling at \$17 per pikul. The plants grow freely with but little care, and should figure among colonial products." This statement, although correct as far as it goes, gives a mistaken idea of the circumstances of the case. The production now is quite equal to the demand, which seems to be very limited, consequently the market is soon glutted, particularly with the oil. A Penang merchant writes me that the demand is very slack at present owing to an over-production of the leaf, stimulated by the high prices paid about a year and a half ago. The article (the leaf) is used very largely in Calcutta and Bombay, principally in the latter place." The same slackness is felt in the sale of the oil, the market for which, by-the-by is London. Another merchant informed me that the last lot of oil he had shipped to England had not found buyers at prices which would pay him to sell.

Unless therefore the use of the leaves and oil could be very materially increased, there seems to be no prospect of profitably cultivating it on a large scale.

P'U-ERH TEA.

In the *Kew Bulletin* for last month (1889, p. 118) an account was given of P'u-erh tea which appears in commerce from the province of Yun-nan in the south-west of China. At the time this account was written Kew had not received from the Foreign Office the very important *Report of a Journey in South-Western China* by Mr. F. S. A. Bourne, Her Majesty's Consular Agent at Ch'ung Kiang.—China, No. 1. (1888), presented to Parliament last June. Attention to this report was drawn in the *Daily News* by a writer who had evidently made himself thoroughly acquainted with the subject. The information supplied by Mr. Bourne respecting P'u-erh tea confirms in every respect the account already given in the *Kew Bulletin*, but he was able to gather locally numerous interesting facts respecting the manufacture and selection of the tea which are given in the following extracts:—

The tea hills are situated six to ten days south-west of Ssu-mao and about the same distance north-west of the Me-khong on both sides of a left bank affluent of that river. It is six days' journey from Ssu-mao to I-bang, the chief of the tea-hills. The road was said to cross two steep hills during the first day and two steep hills during the second day; the third day the road is downhill for the most part to Meng-wang T'u-su which is very malarious; on the fourth day there is a further descent to the Man-nao river; on the fifth day the road is up and down hill for the whole distance; and on the sixth day there is a steady ascent to I-bang. From I-bang to Yu-le is three days' journey, and to I-wu two days'. From Man-nao to Cheng-tung is two days', and from Chengtung to Mo-hei three days' journey. A day's journey may be taken as 18 to 22 miles. Yu-le formerly belonged to the I-bang district, but became the property of a Yao chief who gave it with his daughter when she married a former Hsuan-wei Ssu whose private property the hill now is.

On the 2nd January 1886 the Magistrate was kind enough to take me to see some tea trees at a place called Lu-ying, three-quarters of a mile to the north-west of the city, where he had a big arbour erected of bamboos covered with fir branches to sit and talk in. There were only five trees, of which one stood about 12 feet high, consisting of seven stems, the biggest of about 4 inches diameter; this tree was said to be very old. The magistrate told me that these trees were the remnant of an extensive plantation that was cut down and burnt during the Mahommedan rebellion, and that they were of exactly the same species as that from which P'u-eh tea is made. Whether this is so, or whether these are merely wild tea trees, which are found here and there all over Southern China, it is impossible to say. According to popular tradition, tea was introduced into this part by the great K'ung-ming when he conquered the south.

At all events, it does not seem likely that shrubs on the Ssu-mao plain ever gave good tea, or the leaf would not be brought here from 6 to 14 days' journey south, over bad roads; and, further, it is only within the last eight or nine years that the leaf has been brought out and made up at Ssu-mao at all.

It would be necessary to visit the tea-hills to give a satisfactory account of the trade; meantime the following notes, the result of many inquiries, may be useful. Neglecting the official account,* which does not square with present facts, we must begin with the distinction between tea grown on the hills, I-bang, I-wu, Mansa, and the neighbouring heights, called "yen ch'a" (strong tea), and that which grows on the lower slopes and in the valley of the Me-khong and its tributaries, called "san ch'a" or "yeh ch'a" (wild tea).

The finest tea, made of the young spring leaves from shrubs on the hills, is called "ya ch'a" or "mao-chien." This is only made at the hills, and I could not obtain a specimen. Some of this good leaf was said to go to Yunnan Fu, and there to be made up into balls as big as a man's head, for the Court at Peking. The next quality is called "pai chien" or "hsi ch'a," and is sent in small quantities to many parts of the empire, where very high prices are paid for it.

The tea made up at Ssu-mao is for the most part of the second description, *i.e.*, "san ch'a." During the season, which extends from March to September, the leaf from the lower levels is picked, rolled, dried and sent to Ssu-mao, packed on the backs of oxen; there it is sorted out into heaps according to quality. The manufacture of the leaf into the familiar cake of P'u-eh tea, well known all over West China, goes on all the year round. I saw the process, which is very simple, in the godown of a firm trading under the name of "New Spring Thunder." A large round iron boiler, of the well-known Chinese pattern, is covered by a wooden barrel, held in position by a heavy stone, so that a vigorous jet of steam issues from a single vent at the top. Nine Chinese ounces of tea are weighed out and sprinkled into a copper vessel perforated below, which is then placed over the vent so that the tea is permeated by steam. After about a minute the vessel is removed and the tea poured into a cotton bag, the ends of which are wound round and squeezed into a lump in the middle of the cake. The bag is then placed beneath a heavy

stone, on which a man stands, and pressed into a quilt-like shape, the ends of the bag making the indentation in the centre. The cake is then placed in a rack to cool. When cold the bag is removed, and the cake is in the condition of the P'u-eh tea of commerce. The same process is said to be followed at the hills.

In the case of the particular tea of which I watched the manufacture, the finer sort of Ssu-mao tea, that goes to Ssu-ch'uan, four descriptions of leaf were used—the 9 oz., consisting of $\frac{1}{2}$ oz. fine young leaves and $1\frac{1}{2}$ oz., 3 ozs., and 4 ozs., of three other qualities coarse in proportion to their weight; and the whole art of the process appeared to consist in a judicious arrangement, by which the white delicate leaves were made to take up a conspicuous position on the outside of the cake, while the coarsest sort was carefully billeted in the centre. No. 1 was "paichien;" Nos. 2 and 3 were from the smaller hills in the neighbourhood of I-bang and I-wu, called "so pien" (what is at the side); and No. 4 came from the plain of Me-khong, and was probably wild tea, from which the coarsest leaves had been sorted.

It will surprise no one acquainted with China that the rule that the best tea is to be made up at the hills is very badly observed. What rule is not? In fact, the merchant Thunder, managing partner of the New Spring Thunder House, told me that No. 1 was from I-wu. The truth is that the making up in a cake so favours blending that no tea seems to come from one place or to be of one quality. The only way to get an idea of the trade is to make very broad distinctions. Taken in this way P'u-eh tea may be divided into five classes, viz:—

1. The finest tea, called "mao-chien," "ya ch'a" &c. This is made in small quantities at the hills, and I could get neither reliable particulars as to price nor specimens.
2. Tea of good quality called "hsi ch'a," &c., of which there is a large export to other provinces through Yunnan Fu, especially to Ssu-ch'uan. The tea of which I watched the manufacture above, was an inferior tea of this class (specimen sent to India):
3. "Ping lao," this is "so-pien" tea, just as it is picked without being sorted. Sent to I-hsi or Western Yunnan (Ta-li Fu, Yung-chang Fu, &c.) (specimen sent to India).
4. Inferior tea, made chiefly at Ssu-mao, and consumed in the province of Yunnan.

5. "Chin-t'uan," made in balls for the Ku-tsung and Thibetan market. This is made of the coarsest yellow leaves picked out from other varieties, with a shallow coating of "so-pien" on the outside of the ball (specimen sent to India).

The four first descriptions are packed in a "t'ung," or packet, of seven cakes, which therefore weighs 63 oz., or with the covering of bamboo bark 4 catties. Twelve such packets are placed in a bamboo case, which forms one side of a horse's load, the load being thus 96 catties. The seven balls of class No. 5 are packed in a roll, which is supposed to be of the same weight as a packet, but the Thibetans are regularly squeezed some ounces on each roll.

Prices at Ssu-mao, duty paid, are said to have averaged during 1885 as follows:—

No. 2, "hsi ch'a," 14 taels per 100 catties; No. 3, "ping-lao," 12 taels per 100 catties; No. 5, "chin-t'uan," 9 taels per 100 catties. Carriage from Ssu-mao to Yunnan Fu ranges between 3 taels and 3 t. 5 m. per 100 catties. Duty at Ssu-mao is 7 mace, and *li-kin* 1 tael to 1 t. 2 m. per 100 catties according to quality.

The estimates of the amount of tea turned out during the year varied from 12,000 to 24,000 [?] loads. There are two roads by which the tea comes, one from I-bang through Ssu-mao, and the other from I-wu through Meng-nai to Mo-hei. There are *li-kin* stations both at Ssu-mao and Meng-nai. The most reliable estimate was given me by the *li-kin* collector at Ssu-mao, who said that Ssu-mao sent 3,000 to 4,000 loads in the year, and the hills about 12,000, making in all a production of about 15,000 loads, about half of Nos. 2 and 4, and half of Nos. 3 and 5. Taking-

* Notes from the "Topography," the six tea-hills are Yu-le, Ke-teng, I-bang, Mang-chih, Man-chuan, and Mansa (another extract substitutes Chia-pu, Hsi-k'ung, and I-wu for Yu-le, Mang-chih, and Mansa). The hills occupy an area with a circuit of 800 li. There is a tree called the tea-king, singular as being much bigger than any other tree at the hills. It was planted by K'ung-ming; even to the present day the aborigines worship it. The flavour of the tea varies with varying soils; it is best grown on red earth or amongst stones of different kinds; it then helps digestion, dissipates fever, and acts as an antidote.

12 taels as the average price per load, the gross value of the trade here during 1885 would have been about 180,000 taels, or 45,000*l*.

The supply was said to depend on the demand from Yun-nan Fu, which seems to be the *entrepot* of the trade. The production had been much greater in 1884. The trade has suffered greatly from the rebellion, when the trees were cut down and burnt, and the people who used to buy the tea were killed. The demand from Ssu-ch'uan had increased and had partly made up, but prices had recently been very bad in consequence of the high price of food in that province, which left the people little to spend on good tea.

COFFEE SEASON.—We are sorry to inform our readers, that the Coorg Coffee Crops of the present season are a great failure, and so, we suppose our local shop-keepers will stick on some extra price. The unseasonable rain-fall at Coorg is said to be the cause of much loss of crop, especially in the estates in what is known as "the Bamboo," down at South Coorg. The estates about Somarpett are said to be better off. It is to be hoped that the Planters will meet with better success by the end of this year, when we wish them bumper crops, to make up for present losses. Even in coffee planting, "it is not all gold that glitters" especially considering the enormous cost of the up-keep of large and well managed estates, under European supervision.—*Bangalore Daily Post*.

OVER-FEEDING.

THE interpretation of the term "epicure" is one given over to the luxuries of the table. Seldom, we think, have the teachings of a great philosopher been more perversely misinterpreted than the doctrines of Epicurus. The Epicureans at the first were not sensual, and pleasure and pain were considered respectively the greatest good and the greatest evil. No one who held that pain was the greatest evil would commend gluttony; on the contrary, he would prescribe moderation in all things. If he saw in pleasure the greatest good, he would also see in all that kept the functions permanently healthful, and the senses keenest, the highest means of attaining perfect enjoyment.

Too much meat will produce disease of the liver, kidneys, and no end of trouble. A superabundance of sugars and starchy foods entails a list of dyspeptic symptoms well-nigh endless in their nature. Fruits, condiments, &c., also have their resultant ill-effects. Ordinarily, when a stomach is given too much to do, it sets up the signal of alarm, and declares its presence.

Suppose, now, a case where the individual is suffering from no present indiscretions, but from those of other years. Dyspepsia, heartburn, flatulence, eructations, constipation, occasional looseness of the bowels, dizziness, nervousness, burning in the side, pain in the shoulder, backache, headache—these will be some of the symptoms he complains of. He requires as much, or, perhaps, more, food than he is taking, yet cannot digest it. To reduce the quantity of food now usual with him would be to stop work, and might be unwise. We believe that the physicians who are most successful in treating this immense class of cases are those who bring to the aid of the individual the digestive ferments of the pig, and assist the stomach properly to accomplish what of itself it is unable to perform. The Fairchild Pepsine Tablets are a reliable preparation, often very effectual in relieving the untoward and distressing symptoms of those who, unwittingly, perhaps, have been among the list of the modern Epicureans.—*Nursing Record*, London.

THE MADRAS GOVERNMENT has acceded to the request of the Planters' Association, North Wynaad, and directed Mr. A. M. Lawson, the Government Botanist, to proceed to Wynaad and investigate the cause of the dying off of extensive fields of young cinchonas.—*M. Mail*, Feb. 18th;

CHINA TEAS FROM CANTON.—In a letter to *The Times* in reply to a proposition for a Free Breakfast Table by the abolition of the import duty on tea, Sir Roper Lethbridge speaks of the "cheap and nasty teas of China." The writer apparently forgets that many of the undoubtedly poor quality teas sent to this country from China are to meet a demand. Nothing is said about the better teas; all are put down as "cheap and nasty" alike. The writer is evidently blinded by his own interests, and forgets that China can and does produce teas of a quality in the higher grades which it is extremely doubtful—chiefly from climatic causes—that India or Ceylon will ever be able to attain to, despite the very highest method of cultivation. These teas are generally too costly for the London market. It is this better class teas, and not so much of what comes under the designation of "cheap and nasty," that is now being urged on the Chinese to prepare more largely. China has sent these teas in large quantities in the past, and there is no reason why they should not again form the main bulk of the export.—*L. and C. Express*, Jan. 31st.

FERTILIZERS.—In speaking of fertilizers, Prof. S. M. Tracy, of the Mississippi Experimental Station, dwells with some emphasis on the fact that since all the food of plants is absorbed in either a liquid or gaseous form, plant food, even if it be present in abundance, cannot be used by the plant, unless it is in a form in which it can be dissolved in water or in some of the very weak acids found in the soil. "Insoluble food," says the Professor, "is of no more value to a plant than is raw iron ore to a manufacturer of watch springs. The plant must not only have an abundant supply of food, but this food must be in such a mechanical and chemical condition as to be available to the plant during the few weeks in which it is making its growth. However rich a soil may be in available plant food we need not look for a good crop, if the ground is so hard and lumpy that it cannot be penetrated by the roots, and it is useless to supply any fertilizer which contains plant food locked up in an insoluble form; so that, whatever crop we may attempt to grow or whatever fertilizer we may apply, a thorough pulverization of the soil is essential to success."—*Indian Agriculturist*.

THE TEA, COFFEE, AND COCOA INDUSTRIES OF CEYLON.

(Paper read before the Colonial Section of the Society of Arts, Tuesday, Jan. 21, 1890.)

Tuesday, January 21st, 1890; SIR PHILIP CUNLIFFE-OWEN, K. C. B.; in the chair.

The CHAIRMAN, in introducing Mr. Shand referred to him as a colleague in the work of the Indian and Colonial Exhibition, where he did so much for the introduction of Ceylon tea. The planters of Ceylon were exceedingly fortunate in having their interests represented by so energetic, persistent, and able an advocate. He (the Chairman) was able to do something for Indian tea at the Paris Exhibition, and in 1878, the Grand Gold Medal of Honour was awarded by an international jury to the Viceroy of India for the tea then exhibited from India. He was quite sure that if Ceylon were now to go

in for any great international competition she would win first-class honours for tea.

THE TEA, COFFEE, AND COCOA INDUSTRIES OF CEYLON,

BY JOHN LOUDOUN SHAND.

Ever since Bishop Heber, with missionary zeal and poetic license, drew his well-known word-picture of Ceylon; ever since Emerson Tennent gave the world his classic and unrivalled "Ceylon;" still more, since Ceylon became a favoured outlet for the employment and investment of the youth and capital of the mother country, and a great producing source of common articles of daily food, attention has been much directed towards it, and the name has become familiar to English ears; but changing circumstances, and the rapid march of time, soon make obsolete the history of commercial enterprises which have tropical agriculture for their parent; and my desire is to convey to this Society for the Encouragement of Arts, Manufactures, and Commerce information, as accurate and as condensed as possible, upon industries the promotion of which is mutually important and mutually advantageous to producer and consumer, to mother country and colony.

A sketch of the position and prospect of these industries which have effected so vast and so beneficial a change on the scene of production would be necessarily incomplete without a brief description of Ceylon, and a brief reference to the condition of the island prior to these developments.

Ceylon is situated at the extreme south-east of the Indian empire; it contains about 25,000 square miles, and has a population of about 3,000,000; the land all round the sea-borde is flat, but in the centre of the island there are mountain ranges rising to a height of 8,300 feet above sea level, and it is chiefly upon the slopes of these hills that the cultivation of tea, coffee, and cocoa is carried out.

The climate is very variable, more so in extremes of dryness and moisture than of temperature, the rainfall varying from 35 inches annually in some parts of the low country, to 230 inches on the western slopes of the hills exposed to the full force of both north-east and south-west monsoons; but as an abundant and well-distributed rainfall is essential to the successful cultivation of the products I am describing, these industries are generally carried out under healthful climatic conditions.

Just as the Ceylon of today is the great centre of eastern transshipment, the converging point for steamers from Europe, India, China, and Australasia, so from its geographical position, very early in the commercial history of our world, it became the emporium at which the merchants of China used to meet the Arab traders from the Red Sea and Persian Gulf, and the natural wealth of Ceylon, its ivory and peacocks, its pearls and precious stones in great variety, its cinnamon and rare woods, made it a great point of primitive commercial attraction.

In 1505, the Portuguese, who were then the great navigators of the world, seized possession of the maritime provinces of Ceylon, attracted towards it partly by its geographical position near India, which they already looked to with longing eyes, and partly by the doubtless fabulous rumours of its immense wealth. The Portuguese occupation extended over a century and a half; but beyond the Roman Catholic religion, which they established and somewhat forcibly inculcated, a few descendants of mixed race, who still cling to a Portuguese patois, and honorific names and titles, which the natives eagerly embraced and jealously maintain, but little remains to mark Portuguese supremacy.

In 1656, the Dutch ousted the Portuguese, and held possession of maritime Ceylon for 140 years. Churches, schools, seats of justice, canals, roads, the systematic extension of the great cinnamon and coconut industries, and the introduction and successful cultivation of many economic plants, mark an era of activity and advancement, but material progress was confined to the maritime provinces, for, sullen and secure behind their mountain fastnesses, the Kandyan Highlanders, though willing to trade and barter, resented intrusion. In 1796, the British dispossessed the Dutch, and the treaty of peace of Amiens ceded to the Dutch the richer and far larger island of Java, and the more importantly situated Ceylon remained British.

After several years of constant embroilment and harassing petty warfare, the Kandyan king, was, in 1815, deposed and banished to India, and British rule was established all over Ceylon, the Kandyans themselves, though they had declined to yield to the slave-driving Portuguese or the trade-monopolising Dutch, being not averse to accept a government which offered them a far greater measure of freedom and justice than they had enjoyed under the tyrant who had been dethroned, and from this date, with the exception of one or two instances in which excess of zeal or indiscretion on the one part, and individual desire to gain or regain power on the other, led to petty rebellion, the cordial relations between British and Kandyans have become steadily more and more closely knit, and prosperity has almost continuously advanced.

Coffee (*Coffea Arabica*) was introduced into Ceylon by the Arabs,* who, doubtless, allured by the contrast between the evergreen and beautiful island and their own sterile homes, occasionally prolonged their periodical visits, and have left unmistakable evidence of their incursions in a progeny of mixed descent.

Flowers form a favourite votive offering at the Buddhist shrines, and centuries before the Christian era, this religion was firmly established in Ceylon, and coffee seems to have been at first planted in the vicinity of temples rather for its beautiful and fragrant jasmine blossom than for its more practical purpose; in time, however, the Sinhalese appreciated the excellence of the bean, and became, as all who have access to pure coffee do, a nation of coffee-drinkers, and a small commerce was carried on in coffee with the Dutch, the exports, however, never exceeding 3,000 cwt. Several years after the political settlement, attention was drawn towards the Kandyan hills, as a possible field for the even then surplus British capital and industry, and the success which had attended the crude cultivation of the Kandyans, coupled with the imminent manumission of slaves in the coffee-producing West Indian islands, pointed at coffee as a possible source through which the latent wealth of Ceylon might be profitably developed. Sir Edward Barnes, the Governor of Ceylon, himself formed one of the first plantations, and before long clearings for coffee were made on several different ranges of hills.

The enterprise was of course subject to all the vicissitudes inseparable from an investment of which knowledge could alone be gained by experience. Failures and successes alternated, and on more than one occasion the withdrawal of credit, and the depreciation in value of coffee, caused stagnation and threatened collapse. But, in spite of all difficulties, coffee in time became not only the staple export from Ceylon but the pivot upon which nearly all other exports and imports depended, and the means whereby the island was raised from the mere negative position of a naval and military station, and attained a height of progressive civilisation unsurpassed in her Majesties' dominions.

There are, of course, many operations necessary before forest land can be turned into a coffee plantation. After the selection and survey of the land, the trees on the area intended to be planted are felled, and when sufficiently dry are burnt off. The land thus

* Notwithstanding the high authority of Tennent, we have been compelled on full inquiry to hold the conviction that coffee was not known in Ceylon until the Dutch introduced its culture.—Ed. T. A.

covered with charred logs and sticks is roaded and drained, and evenly laid out for the digging of pits for the reception of the young plants. These pits, which are dug in even lines generally five or six feet apart, and to a depth, according to circumstances, of from fifteen to twenty-four inches, are carefully filled in with the ash and decaying vegetation of which the surface soil is composed. The coffee plants, meanwhile, having been raised in nurseries, are planted out in the pits as soon as the rainfall is sufficiently abundant. The young trees have many enemies—rats, crickets, and insects of many kinds; but new plants are constantly supplied where vacancies occur, and soon the trees require to be topped, to reduce them in height for convenience of cultivation, and to encourage them in throwing out lateral branches. Generally in the second year after planting the young trees begin to blossom, and seven months afterwards yield their first fruits: and as they increase in age and strength, until they reach maturity, so should they increase also in yield.

The operations connected with the harvesting and preparation of coffee are very simple, the bright red cherries, generally containing two beans each, are brought into the pulping-house, and from there passed through cylinders or discs, commonly called pulpers, by which operation the skin, which is used for manure, is separated from the beans, which fall into a cistern, where they are left to ferment until the mucilage with which they are covered can be freely washed off, the beans are then dried sufficiently to admit of their safe transport to Colombo, where, after further drying, the outer husk, called the parchment, is peeled off. They are then sized and packed in casks, and are ready for the roaster.

It is painful, however, to record that the coffee industry of Ceylon, which converted nearly 300,000 acres of trackless forest into busy scenes of active life, which found an outlet for many of the younger sons of England, who, after passing through the various ranks and gaining the necessary knowledge, generally acquired plantations of their own, and returned to spend the fruits of their industry in their native land: which gave employment to 300,000 agricultural labourers of British subjects of Southern India, and to more than that number of the natives of Ceylon, who as mechanics, carriers, purveyors, and in numerous other capacities, depended upon coffee; which covered the island with a network of roads, and caused the hills to echo with the shrill whistle of the locomotive, where, a few short years before, the elephant's trumpet and the sambur's bark were the solitary sounds; which provided the revenue by which Government, with the improved light of science, has restored many of the ancient irrigation works, magnificent in conception, often faulty in construction or design, and thus provided for many who literally cast their bread upon the waters—the blessing of abundance; which placed education and Christianity within the reach of all, has dwindled to but a shadow of its former self, and had other enterprises not arisen, which promise to be yet more extensive and yet more permanent, the history would, indeed, be a sad one.

From 1867 to 1870, the exports of coffee were highest, and large tracts of land were rapidly being brought under cultivation. In 1868, however, in one of the youngest and most promising districts, a fungus (*Hemileia vastatrix*) attacked the leaves of the coffee tree, and soon spread over all the coffee-producing districts.

It was thought lightly of at first, and sudden as its appearance so was its disappearance looked for, but a fungus in a climate of equable temperature, where there is practically no check of season to retard development, and where a large area of land is planted exclusively with the one thing it feeds on, is a terribly dangerous enemy. The energy of the tree, which should have gone to the production of fruit, was diverted to the incessant reproduction of leaf. All remedies which science, aided by liberal cultivation, could suggest were tried. Fresh seed was introduced from various coffee-producing countries, and a variety of coffee, a native of West Africa, called "Liberian" a larger and apparently more robust tree, was import-

ed from the West Coast of Africa and largely planted, but it was powerless to resist the fungus; and despite a large increase of coffee-bearing land, the exports began to dwindle.

In 1873, a great stimulus was given to the cultivation of coffee by a remarkable rise in prices in European markets. There was at the time a considerable influx of capital. Credit was abundant. Coffee property and forest land went up to fabulous prices, and it is easy to see now, with the lurid light of baffled hope, how economic conditions were often set at defiance, and the island was brought to the verge of a general financial crisis.

NEW PRODUCTS.

It was fortunate for the future of Ceylon that experiments had been going on in the introduction of new products, and Dr. Thwaites, the late Director of the Royal Botanic Gardens at Peradeniya, near Kandy, who, from the first, took a very grave view of coffee-leaf disease, had done much to instil into planters the desire to try new things, and fibres and foods, dyes and drugs, gums, spices, tobacco, were all extensively tried with varying success. A word or two must be said about the cultivation of cinchona, the quinine-yielding tree, because the export table tells such a remarkable tale of rapid development, and Ceylon, which in 1876 shipped 16,842 lb. of bark, and in 1886 15,000,000 lb., an increase of nearly a thousandfold, it has been the great agency through which this valuable medicine has been within the reach of all.

Cardamoms also (*Elettaria Cardamomum*) deserve mention. In 1876 4,965 lb. were exported; and in 1887, 321,560 lb.

Cinchona trees could be freely interspersed between the rows of coffee, and both these articles of commerce and some others formed valuable adjuncts by which many planters were able to tide over the period between the cessation of coffee crops and the commencement of tea harvest; for it was to tea, which had now shown its thorough adaptation to the circumstances of Ceylon, that all looked for a restoration of prosperity.

Tea (*Thea camellia*) was introduced into Ceylon by the Dutch, but does not seem to have been cultivated for commercial purposes. In 1842, an experiment was made on a considerable scale, but though the growth of the tea trees was favourable, the mystery then supposed to attach to the manufacture of the leaf prevented cultivation of the plant being extended; and it was not again until 1866, after tea had been very successfully established in India, that it seems to have again attracted attention in Ceylon. The seed from the trees which had long been growing uncared for in the Botanic Gardens was planted out, and a Commissioner was, at the request of the Planters' Association of Ceylon, sent by the Ceylon Government to India, to report upon the tea enterprise. The result of the report was so far satisfactory that one or two fields of tea were planted on systematic principles as soon as seed was procurable. Coffee was, however, still doing so well that it almost monopolised European energy, and it was not until the ravages of the coffee fungus made it plain that ruin could only be averted by the substitution of other products, that the cultivation of tea was entered upon extensively, and though directly the result of the failure of coffee, Ceylon started tea with certain advantages.

The fact that excellent tea could be manufactured, and an abundant yield secured under suitable conditions, had been already established, for the early formed

gardens had been supplying local demands, and had proved the London market with success. From these gardens a good deal of the seed for the formation of nurseries was procurable, and the experience which the pioneers had gained was freely placed at the disposal of others. Ceylon had also the great advantage of being able to avail itself of the advice and assistance of Indian planters, and to profit by the experience which, in the face of difficulty and obstruction—which in great measure paved the way for Ceylon—had built up the great Indian tea enterprise.

There was a further advantage which, though often painfully felt, has given an element of safety to the capital invested in tea in Ceylon. The general distrust naturally arising from the failure of coffee caused a great withdrawal of credit and purchasing power, and borrowing facilities were at so low an ebb that, though success was apparent, it had often to be attendant upon means, and the enterprise has been built up on a sound financial basis, entirely free from any rush of speculation; but still the progress has been marvellous, and perhaps unprecedented in commercial history. In the Ceylon Customs, during the year ending 30th of September, 1880, 114,815 lb. of tea were exported; 1885, 4,352,895 lb.; 1889, 32,516,682 lb.; and during the current year more than 40,000,000 lb. will probably be exported; and as tea has thoroughly adapted itself to the conditions of Ceylon, which possesses the great advantage of a good climate, a cheap and abundant labour supply, and unrivalled facilities for the transport of produce from plantation to market, and as there is still much suitable land available, it is impossible to assign the limits of the enterprise.

The various operations connected with the formation of a tea plantation are very similar to those required for coffee cultivation. The young plants are removed from nurseries and placed in pits, at distances from one another varying according to circumstances, but an acre of tea land generally contains about twice as many plants as an acre of coffee.

A year or so after the planting out of the young trees, which grow very rapidly, they are cut down to a height of about three feet, and encouraged, for convenience of cultivation, to assume the form of a bush rather than of a tree; and as soon as the tree is old enough the work of plucking commences. Tea is made from the very tender leaves and buds, great care being required not to impair future plucking. The tea harvest in Ceylon is perennial, except when the trees are taking the rest which is annually imposed upon them by pruning. The whole area of the plantation requires to be plucked over, according to climatic circumstances, from seven to 12 days. The green leaf is then carried to the factory, and weighed and spread out on trays to wither, four pounds of green leaf generally giving a return of about a pound of manufactured tea. After sufficient moisture has been evaporated, and the leaves have become flaccid, they are placed in heavy rollers, and all the cellular tissues are thoroughly broken up. They then go through a slight process of fermentation, during which the colour changes from green to a bright copper. They are then passed through furnaces and thoroughly baked, and here the actual manufacture ends, and all that has now to be done is to sort into the various grades of orange pekoe, pekoe, pekoe souchong, &c., &c., and to pack in lead-lined chests, when the tea is ready for its destination, each of these operations is carried out as far as possible with the assistance of machinery, and requires scrupulous cleanliness and unremitting attention; and it is perhaps owing as much to careful preparation as to natural advantages that, since Ceylon tea became established in London as a commercial article, it has averaged higher prices than the tea from any other country.

What coffee planting did for Ceylon has been already told, and its great successor—though the immediate profits derived from tea cultivation may not always be so great as from coffee—has placed the island on a firmer and more permanent basis.

The cultivation of coffee was confined to a hill zone, the limit of which varied with soil and climate; but both above and below that zone coffee refused to yield

crops, and it was also especially sensitive to ill-treatment, and at once resented neglect. The area available for coffee was therefore limited, and as nearly all suitable land had been planted, and when trees got old and exhausted the same land could not be replanted, though the end of coffee has been precipitated by leaf disease and accompanying pests, it was in the course of nature bound to come; and the question so frequently asked—whether Ceylon is likely to become a large coffee producer again can, so far as the present generation is concerned, be answered in the negative.

Tea, on the other hand, grows with the greatest freedom. If left neglected, it triumphs over weeds, and asserts itself in the midst of a dense jungle undergrowth. It flourishes equally from sea level to the tops of the higher mountain ranges, so much so that it is still an open question whether a tea estate in the low country, with its large yield of strong but somewhat flavourless tea, or one at a higher elevation, where reduced yield is compensated for by increased flavour, is the better investment.

There are few, if any, economic plants which thrive over so large a portion of the globe as tea, and though an expansive market to grow for, its very hardness would give rise to the danger of over-production were it not that the cultivation, plucking, and manufacture of tea require so much human labour that it can only be grown with profit where population is dense, and requirements of life are cheap, and in this respect Ceylon possesses unequalled advantages. The native population would be sufficient for all wants, but it will generally only labour intermittently, as the Sinhalese have their own fields to cultivate, and the religion of Buddha requires the observance of many festivals; and as a resident labour force which will labour uninterruptedly is indispensable for the successful cultivation of both tea and coffee, the labour force is recruited from the densely populated villages on the Malabar Coast, where life is hard and food oftentimes scarce; and when the coolies have crossed the narrow strip of blue which separates Ceylon from the mainland, and which is as precious to it as the English Channel to this island, they readily accept the bettered condition of life, and though under no indenture, and free to come or go at will, many settle down on the plantation where they are comfortably housed with their wives and children, and never return to their native land. A full grown man's wages are something under sixpence a day, and for two-thirds of this sum he can purchase as much rice, curry-stuff, betel, tobacco, and salt fish as he can consume, and neither custom nor climate requiring a lavish expenditure on clothing, though the love of dress is strong, his means are ample for his humble wants, and many of these labourers remit money to their relatives in India. Each coolie is allowed a piece of ground on which he cultivates vegetables, many of them keep poultry and sheep, and some rise to the dignity of possessing a cow.

The absolute dependence of the planter upon his coolies for success, the ready way in which they respond to generous treatment, and their really improved condition of life, promote a thorough understanding between master and servant; they benefit and suffer together, and during the severe strain of bad times which followed the failure of coffee, conscious of their employers' difficulties, coolies not infrequently volunteered to accept reduced wages.

In Ceylon, apart from many of other items of expenditure, it requires about two-thirds of a day's labour to produce a pound of tea; thus, if the average rate of labour is sixpence, fourpence is expended upon the manual labour necessary to bring a pound of tea to market. In countries where the day's wage is a shilling, eightpence would have to be expended on manual labour; and though there are several parts of the British empire where tea may be grown profitably for local consumption, cheap labour is indispensable to compete successfully in European markets.

Cocoa (*Theobroma cacao*) was introduced into Ceylon by the Dutch; and though plants were occasionally distributed from the Peradenya Gardens to different parts of the island, and the desirableness of cultivat-

ing it for commercial purposes was constantly impressed upon planters by the directors of the gardens it was not until 1873 that an experimental shipment was sent to London from the Pallakelle estate, where a few trees had been planted for ornamental purposes. The report on this shipment was so satisfactory that a considerable area on the estate was soon planted, and the decadence of coffee induced others with suitable land to follow the example, most of the plants being supplied from nurseries raised on the estate mentioned, though several varieties of the plant were also introduced. Though the enterprise has assumed considerable dimensions, it has been somewhat of a disappointment. The quality of the beans is excellent, but the plant is very subject to insect pests, and the cultivation requires a well-distributed rainfall, rich soil, and shelter from wind—conditions not often found associated in Ceylon. As the trees get older, and draw nourishment from deeper sources, there is reason to expect they will be less subject to pests, and less dependent upon weather, but there is no immediate prospect of the export being large, though it might certainly be trebled if the natives, among whom many plants have been distributed, took to cultivating it. Most of the best cocoa land in Ceylon is in the hands of natives in sheltered pockets of rich soil, as the Kandyan valleys; and though in time they will probably awake to the advantage of cocoa cultivation, they are generally slow to embark upon any new enterprise.

Cocoa, at three years old, begins to yield, and there is no prettier sight than a cocoa tree bending under its weight of massive bright pods. The cultivation is very simple, and the preparation on the estate consists in removing the beans from the ripe pod, and drying them sufficiently for safe shipment to European markets. When the beans reach the factory they are ground, roasted, and husked, and they can either be procured in the pure form of cocoa nibs, or in one of other of the many preparations of cocoa, after some of the fat, of which cocoa beans contain 50 per cent., has been extracted. This cocoa fat, or butter, which has a remarkable power of not becoming rancid, would be used for many manufacturing purposes if it were procurable, but, meanwhile, it is chiefly taken up in the composition of chocolate cream and sweetmeats of various kinds.

Though the consumption of cocoa—as custom requires us, though inaccurately, to spell it—is increasing, the increase is but slow; it is by far the most nutritive of all non-alcoholic stimulants, and deserves a far higher place as an article of food.

ADULTERATION.

Medical testimony is almost unanimously in favour of the moderate and judicious use of tea, coffee, and cocoa, and the criminal statistics of the country show how great a social and moral reform the substitution of these wholesome non-intoxicant stimulants for deleterious intoxicants has effected, but much remains to be done, for while there are no more pleasant and nourishing beverages than good tea, coffee, or cocoa, there are no more nauseous compounds than the beverages frequently sold and supplied under their names.

Those whose means permit of the purchase of tea in chests straight from the plantations, or of the treatment at home of raw coffee or cocoa nibs, should have no difficulty in securing excellence, but the vast majority are compelled to buy these articles ready for use, and are thus practically in the hands, and at the mercy, of the tradesmen who supply them. Coffee has been at all times much adulterated, but since the mixture and sale of chicory and dandelion root with coffee was legalised in 1882, and under the shield of a Government stamp, it became permissible to sell any rubbish as a coffee mixture, the steady decline in the consumption of coffee showed how detrimental that legislation has been to producer, consumers, and revenue. Recent analyses of so-called coffee showing in many cases a mere trace of coffee, prove the utter demoralisation of the trade; and as the unit of coffee may, for purposes of comparison, be taken at 1s. 3d., and the unit of chicory and the numerous other adulterants at 3d., it is obvious that it is directly against the tradesman's interest to sell pure coffee. It is not

because coffee is scarce, or for want of purchasing power, because the Dutchman drinks more than 20 lb. per head, and taking 3 lb. of coffee as supplying the same quantity of beverage as 1 lb. of tea, Holland consumes more of the allied beverages than the United Kingdom.

The shameless adulteration of coffee with all sorts of vegetable and even animal substances is so freely carried out, that even the legitimised and, at all events, harmless chicory is in itself much adulterated. What should be one of the greatest competitors in the race against alcohol has been virtually scatched, and a generation is growing up which knows not what coffee means. The various preparations of cocoa are composed largely of arrowroot and other starchy substances, many of them containing but a flavouring of cocoa, and it is this admixture of uncooked starches which gives rise to the prejudice that this most valuable article of food is difficult of digestion.

The enormous expenditure incurred in advertising leads to the belief that the Customs tables are no gauge of the quantity of food consumed under the names of coffee and cocoa, and in addition to the 10,000,000 lb. of imported chicory, it would be interesting if it were possible to learn how many pounds of British chicory and dandelion root, of starches, roasted grain of all sorts, and vegetable refuse generally, the British public unconsciously imbibe.

The free breakfast table is admirable in theory. The pure breakfast-table would be ten times more beneficial, and is far more practicable. Customs vigilance has almost stopped the importation of adulterated tea, though much comes into consumption which, though not condemned as unfit for human food, is entirely lacking in the pleasant and stimulating qualities which good tea possesses. Inferior teas, often the mere sweepings of Chinese stores are passed into consumption with a label such as this—

"PURE CEYLON TEA"
Blended with China.

in which "blended with China" is almost invisible, much to the detriment of the British tea growers, and much to the loss of the consumer who, if his palate and his patience will allow him to consume a packet observantly, will find at the end that he has been drinking an unpleasant and, to him, an unprofitable thing at a greater cost per cup than he could have got a good article for, because he requires to use so much even to impart a decent colour. Another legalised trade practice constantly perpetrated is the adoption upon packets of a name very closely resembling that perhaps of a well-known plantation in Ceylon; and with the object of checking this, the honest dealer or the anxious consumer can always find out at the office of the Ceylon Association in London whether such names are genuine or not.

THE TEA DUTY.

The tea duty is a question so nearly one of party politics, that this is not the platform upon which to discuss it; but I shall, in a few words, point out the present effect of the duty, and how a reduction or abolition might act. The duty, sixpence per pound, which brings £4,600,000 into the exchequer, falls, of course, proportionately, so much more heavily upon low than upon high-class tea, that it offers a premium to the importer to send in good tea; and while the adulteration of coffee or cocoa beans is easy of detection, a dried and roll'd-up leaf is more liable to spurious imitation; besides, tea requires special protection against itself, for the leaves which have been once used can be rolled up again, and as has been before pointed out, it is only the very young shoots which possess the necessary properties to make good tea. A vastly increased quantity of tea might be made by waiting until the leaves got older, but then they would be defective in all the qualities which constitute good tea. Reduce this premium and the proportionate Customs vigilance, and you reduce the incentive to produce good tea. Remove them, and you go a step

further, and though it would at first sight seem that a reduction of duty would be favourable to both producer and consumer, I believe in this case the effect would be directly opposite.

It is doubtful whether a reduction of duty would be followed by largely increased consumption, because the average retail price of tea is probably threepence or fourpence per pound less now than it was four years ago; but consumption remains almost stationary, though, as the Chancellor of the Exchequer has twice pointed out, the increased consumption of Indian and Ceylon teas mean, on account of their greater strength, an increase in number of cups of tea, and the standard of much of the tea which reaches the poor is already so low that, as an article of human food, it is absolutely valueless. The immediate effect of reduction or removal of duty would be that a large quantity of refuse tea, which the Chinese decline to consume themselves, would be forced on the market to the detriment of the British tea grower, who, whether in India or Ceylon, has invested largely in machinery or appliances for manufacturing good tea. The secondary result of reduced Customs vigilance would be that the hedgerows of Southern Europe would largely contribute to the breakfast tables of England, and than the tea market would become so demoralised that if it was treated by Act of Parliament as coffee has been, admixture would be legalised, and beech tea, sole tea, and a hundred other teas would be freely sold, and with the death-knell of coffee still ringing in our ears we should await the doom of tea.

When I was honoured with an invitation to read a paper before this Society I hesitated, my first thought being, what can I say that has not been more ably said before? Believing, as I do, that Imperial Federation can only be firmly founded on mutual commercial advantage, and that the extension of knowledge is the first step towards federation, I gratefully accepted the opportunity of drawing attention to great colonial industries. And how rapid the changes in these industries are! When the Ceylon figures were compiled for the Colonial and Indian Exhibition, but four short years ago, the maximum export shown was 3,796,884 lb., and this year we have to deal with more than 40,000,000 lb. In 1885, the consumption of British-grown tea was 38 per cent. of the total, last year it was 67 per cent.; and this displacement of China tea by British-grown tea means a very large annual draft upon the mother country for machinery, lead, iron, and many other articles of British manufacture, besides a large bill for piece goods of various kinds, the clothing of the million and a half British subjects directly depending on tea cultivation.

The Indian and Ceylon tea industries represent an investment of British capital of probably £30,000,000 sterling, and to possess within ourselves the power of producing and consuming is our very strongest Imperial bond, though so far but very scantily recognised. A description of special industries in special localities is necessarily narrow and lacking in general interest, but I venture to think there is much in the agricultural history of Ceylon capable of profitable application to other parts of the Empire.

There are lessons to be learned from the failure of coffee, and the various products which succeeded it, which may directly benefit many parts of our tropical empire, and there is the great general lesson from which all may learn teaching how the planters of Ceylon manfully met difficulties which seemed once insuperable, and by their efforts have restored prosperity.

I append to these remarks a Table showing the average consumption per head of population of our non-alcoholic drinks, and the progress they have made; and while the figures for 1889 show tea and cocoa as almost stationary, there is again a considerable falling off in the consumption of coffee and chicory. I specially commend to the workers among the poor the task raising the standard of these drinks, and I trust my brief and necessarily imperfect sketch may stimulate interest in colonial enterprise, and tend to the fulfilment of the moral obligation which the mother country owes the colonies.

STATISTICS AS TO THE NON-ALCOHOLIC DRINKS OF THE PEOPLE OF THE UNITED KINGDOM.

POPULATION.		AVERAGE CONSUMPTION PER HEAD OF POPULATION.			
Years.	United Kingdom.	Tea.	Coffee.	Cocoa.	Total.
		lb.	lb.	lb.	lb.
1856	28,011,034	2.26	1.25	.13	3.64
1857	28,188,280	2.45	1.22	.09	3.76

1888	37,440,505	4.95	.82	.49	6.26

DISCUSSION.

Mr. HYDE CLARKE said the paper dealt so exhaustively with the subject, that no one not being a specialist, or connected with the Island, could venture to add anything to it. It was very gratifying to listen to such a paper, which gave the whole history of the subject from the beginning, and dwelt especially upon its most interesting aspects, showing the benefits which had been conferred on the local population on the one hand, and on the other the way in which the enterprises referred to had made an opening for numbers of young men in England, who, after spending some years in Ceylon, had come home to enjoy the prosperity which they had acquired by their enterprise and energy, and to spend the remainder of their lives in their native land. One very interesting feature, though a melancholy one, was the history of the coffee industry, the failure in which, however, was not limited to Ceylon, for in many parts of the world similar plagues had made their appearance in such virulence that all the coffee trees had to be rooted up as the only means of checking the progress of the disease. Happily, however, their countrymen in Ceylon, when their efforts were foiled in one quarter turned to another, and had raised the production of tea to such a height of prosperity, that the history of the cultivation was almost a romance. He cordially congratulated Mr. Shand on his paper.

Mr. FOLKARD said all who were connected with Ceylon ought to feel indebted to Mr. Shand for mentioning so prominently the question of the possible reduction of the tea duty, which many people hoped might be announced in the forthcoming Budget. He thought those who considered the matter from all points of view would agree with Mr. Shand in his conclusions. Sir Roper Lethbridge had recently addressed a letter to the *Times*, in which the enunciated very much the same views; but though he perfectly agreed with

both Mr. Shand and Sir Roper Lethbridge, there was another way of looking at it, and a correct judgment could only be arrived at by considering the various parties engaged in the business. He had been informed lately by a gentleman who had made inquiries on the subject, that the general price of the tea sold in the poorer districts in London and the country was 1s. 8d. Of that 4d. was the retailer's profit; he intermediate dealer, who purchased in Mincing-lane and supplied the retailer, required 5d. per lb., and sometimes 6d., which reduced the price to 10d. or 11d. from which, after deducting the duty, you only had 5d. remaining as the original price of the tea which was retailed at 1s. 8d. Very few dealers could purchase decent Ceylon or Indian tea at that price, and therefore they must be content with the cheapest varieties from China, which were sold at 4d., 4½d. and 4¾d. The result was that Ceylon tea, as a rule, never reached the mass of the people at all, but was consumed by those who could afford to give 2s. or 2s. 6d. per lb. The duty, therefore, might be said to keep the poor from purchasing Ceylon tea. But there was another way of looking at it. If 6d. a lb. were taken off altogether, the cheap China tea could be sold to the poor at 1s. 2d., but the Ceylon tea would have to be charged at least 3d. a lb. more, and the question was whether the poor would recognise that it was worth fully 3d. a lb. more in flavour and strength, and be willing to pay the entire price. The percentage of difference between the two qualities would be greater with the duty taken off than with it on, and therefore he supported Mr. Sand's view that if the duty were removed, Ceylon tea would be handicapped more than it was at present.

The CHAIRMAN, in proposing a vote of thanks to Mr. Shand, said he must refer for a moment to the efforts which that gentleman was making to introduce Ceylon tea into Paris, where the tea sold was generally more horrible than could be imagined, and the price charged was enormous. Another question in which he was much interested as a teetotaler was that of good temperance drinks, and his experience was that cold tea was the very best drink of all. On that ground also he had reason to wish success to Ceylon tea and Indian as well. If the Chancellor of the Exchequer would help them in the tea business, he would assist the teetotalers and counteract the harm which he feared Mr. Gladstone had done by the grocers' licenses. He concluded by moving a hearty vote of thanks for the paper, which did great credit to the Section.

The vote of thanks having been passed

Mr. SHAND, in reply, said they could not expect to make the French a nation of tea-drinkers all at once, but he was much indebted to the Secretary for placing means at his disposal which enabled him to introduce Ceylon tea to the Parisian public. He had no doubt that good results would follow, but they could not expect these to be seen immediately, as was the case with the Indian and Colonial Exhibition of 1886, the success of which was so much due to the exertions of the Chairman. That Exhibition created for many of them an era they would never forget, and they all owed a deep debt to Sir Philip Cunliffe-Owen for the zeal, energy, and courtesy which he displayed in connection with it. He was sure that if Sir Philip could tear himself away from South Kensington for a time and pay a visit to Ceylon, he would find that his fame had preceded him, and that he would receive a most cordial welcome.

ANOTHER PROMISING TEA COMPANY.—We attract attention to the report of the proceedings at the annual meeting of the Talgaswela Company, and to the opinion of so competent and prudent a judge as the Chairman, Mr. T. O. Owen, that in all probability this Company will be paying 20 per cent on its capital after next year. This we can well believe when we see as Mr. Shelton Agar stated that 716 acres have been planted with tea for less money than was originally estimated for 500 acres. Well done the Talgaswela management, say we!

PLANTING IN EAST AFRICA.—Mr. D. J. Rankin in a paper in February's *Fortnightly Review*, speaking of the Shiré Highlands, says:—"Vast tracts of land that would produce immense quantities of oil-seeds, rubber, sugar, rice, maize, coffee, and other valuable commercial articles are now awaiting the advent of British enterprise, which, with improved conditions of communication with the coast, will have every prospect of immediate financial success."

JAPANESE TEA FOR RUSSIA.—Last year there was established in Kobe a company styled the Nippon Tea Manufacturing Co., with the object of working up an export trade in tea with Russia, but so far the expenses of the concern have exceeded the profits made. It is, however, intended to continue the scheme, and a special meeting of the Association of Tea Merchants is to be held in the Keesi Kwan, Kobikisho, Tokyo, on the 31st instant, to consider the idea of subsidising the Nippon Tea Manufacturing Company.—*Japan Gazette*.

INDIAN TEA fared rather worse than Ceylon at the Paris Exhibition to judge by the official report thus noticed in the *Madras Mail*:—

Without a duly qualified manager everything went wrong, and delays and difficulties with exhibitors and contractors ensued. Then the Indian Tea Association, instead of keeping the management of the Tea Department in its own hands placed it in charge of a City firm, who pushed their own trade mark; and the tea business was handed over to refreshment contractors, who "very naturally considered their direct pecuniary benefit." A prohibitive price prevented the sale of tea, whilst beer-drinkers crowded the seats in the limited space designed only for tea drinkers. "The French Press called the Indian Pavilion the 'Temple of Tea,' but by thus depraving its use, the opportunity was lost of inducing an inquisitive and imaginative people like the French to linger amidst Oriental and appropriate surroundings to taste a new beverage offered them by native servants brought moreover from the French Colony of Obandernagore."

BUSHIRE AND BRITISH TRADE WITH PERSIA are thus noticed in the *London Times*:—

But at Bushire, and in a certain degree at Ispahan, there are signs that some activity of life is possible yet for Persia. Bushire is the chief port in the gulf, and though it offers a poor harbour for vessels, British trade is there fairly active. The European portion of the town is "as unmistakably British" as "might be those of Aden, Colombo, or Hongkong." It is the centre from which British and British-Indian trade finds its way all through Southern Persia. What the extent of that trade already is may be learned from some of the statistics give by our Correspondent with regard to Ispahan, "the northern limit of undisputed British predominance." Nine ba'es out of every ten that pass through or are discharged here bear British trade-marks. If the principal firms in the town bear German names, none the less do they deal in by far the largest proportion of British goods. The imports, mentioning them in the order of their bulk, consist of cotton goods from Manchester and Glasgow; copper sheets from London; tin and zinc from India and Java; woollen stuffs and cloths from Austria and Germany (why not from Bradford?); and minor matters from India, Russia, and Marseilles. Thus the bulk of what Ispahan and Southern Persia consume of foreign goods comes from England; and much of what Persia produces finds its way to London in return. The chief part of this is raw material, the chief exception being carpets, for which an immensely increased demand has arisen of late years in England, France, and America. The old carpet industry of Khorasan, and other Persian provinces has been revived, and may yet be greatly extended. It is fortunate, too, that European dealers have learned that for these beautiful things to find favour with Western buyers they must be of purely Oriental design and made in the old way. Thus there is at present little chance of the serious deterioration of this interesting art.

THE CEYLON SPINNING AND WEAVING
COMPANY (LIMITED).

The adjourned general meeting of the Shareholders of this Company was held at the offices of the Company, No. 9 Queen Street, Fort, at 3 o'clock yesterday afternoon, for the purpose of receiving the report of the Directors and the statement of accounts for the year ending 31st December last, both of which have been already given in the *Observer*. There were present:—Mr. R. L. M. Brown, Chairman of the Company (presiding), the Hon. J. J. Grinlinton (Managing Director), the Hon. W. W. Mitchell (representing the agents and secretaries), Mr. Edmund Walker, Mr. C. Ramalingam (directors), Messrs. W. T. Holmes, W. Atherton (manager), D. Harris, J. Headrick, W. E. Mitchell, G. B. Sparkes, H. P. Rudd, T. H. Summerfield, P. L. A. Moothyah Chetty, A. V. R. A. Adaicappa Chetty, V. P. R. P. L. Vadoogan Chetty, A. R. M. A. M. V. R. Aroonachalam Chetty, S. M. E. M. Annamalay Chetty, W. D. Carolis, Carimjee Jafferjee, H. Bastian Fernando, and C. Wyrarnoothoo Pillay, and (by proxy) W. L. De Soysa.

This being an adjourned meeting no minutes were read, but the notice calling the meeting was read as a matter of form.

The CHAIRMAN asked for the report of the Directors to be taken as read as they had all received copies of it, and this being agreed to, he asked them to follow him through the accounts. Of course he might preface any remarks he had to make by stating that what they were rendering now was practically a statement of expenditure, because, as they were aware, the Mills had only been in course of erection during the past year and consequently had been earning nothing. The statement of accounts before them therefore practically represented what they had spent since the formation of the Company. The first item they came to was that of capital, from which the shareholders would see that the Company had received R201,170 upon 4,000 shares. They would observe that, unfortunately there had been very great irregularity in the manner in which the calls had been paid up on those shares, and that while some had paid in full and others in advance, several had been very far behind indeed with their calls, so much so that in accordance with the Joint Stock Ordinance they had been compelled to publish a statement of those who were in default or arrears, which would be found annexed to the balance sheet. The total amount of such arrears unfortunately amounted to R14,010. He had alluded to this matter at their previous meeting, and while to a certain extent the amount of arrears was reduced there was still a considerable sum outstanding. It was to the interest of the Company that they should get in the capital as regularly as possible, because without it the business was—he would not say crippled, but rendered more troublesome than it otherwise would be. The next item on the debit side of the balance sheet was "amount of loans R200,000." Now he was aware that it had been asked in some quarters why such a considerable amount should have to be raised. The reason of it, he thought, was pretty apparent on the face of the accounts. They would observe that with the total amount of capital received from the shareholders—R201,170, and with the total amount of loans—R200,000 they arrived at a total of R401,000 odd. Now had the directors called up the full amount on those 4,000 shares they would have been entitled to expect R400,000, which was exactly the amount they had to provide, but it was felt that to call up this amount so suddenly might press inconveniently on many of the shareholders, and with

the view of rendering the burden as light as possible, or distributing it as much as possible, the Directors considered that it would be advisable to take advantage of the money which was offered to them elsewhere rather than call upon the shareholders to find it all at once. Of course that would be liquidated out of the calls which would have to be made and which would be paid up from time to time so that the amount of calls would be reduced just as they received the calls from the shareholders. The next item they came to was debts—debts for which acceptances had been given for machinery, and debts for machinery not yet drawn against. The machinery represented by the first item—R82,671—was already on the premises, but the acceptances for it had not yet been matured. The next item—R31,935.25 for machinery not yet drawn against—represented machinery supplied, but in accordance with the terms of purchase it was supplied on credit. As, however, it was a liability incurred by the Company they were bound to place it in the balance sheet. The next item was the amount deposited by shareholders in anticipation of calls—R3,480. The only remark he could make on that was that they were sorry all the other shareholders did not benefit by the good example. Then there was the amount of interest due on loans—R2,259.51. Of course a large proportion of this—a very large percentage if not the whole of it—would be recovered from those shareholders who were in arrears in payment of their calls, because they would be called upon to pay interest from the time at which the call was made, or in default of their doing that it would be deducted from their dividend. The next two items—balance of wages due and due for cotton seed—explained themselves. The item of R175 to Marine Insurance Fund account also explained itself. It was the profit on the Insurance Fund of cotton coming from Tuticorin, which it had been decided should not be distributed, but should form a fund in the Company to provide against any possible loss. Coming to the Suspense account there was the item of R2,258.43 for cotton seed sold and interest. The advantage of this was to a certain extent apparent: the former was not considered as profit, although perhaps strictly speaking it might be, but it had been regarded as a sort of fund from which the distribution of cotton seed to those who were anxious to undertake the enterprise might be supplied, and consequently it had not been regarded as strictly profit. On the credit side of the accounts were the amounts represented by the freehold land and buildings at Welawatta: the land consisted, as they were aware, of 28½ acres which they purchased from Government for R14,489.90. With regard to the buildings, for which R109,708.60 was put down, he thought that anyone who took the trouble to go round to the works and observe the vast amount of labour and material which had been required to build them would, if he had any knowledge of architecture, admit that they had got ample value for their money. There had been no waste, and he did not think that buildings of such dimensions and solid structure could be erected anywhere in the island at a lower price. The items for movable property—machinery and tools—of course represented exactly what they had paid for them: there was no depreciation written off inasmuch as the machinery had not begun to work on the 31st of Dec. Coming to stock-in-trade the amount of R62,183.99 seemed a considerable item. He might explain that it consisted of certain portion of machinery and of certain relays or duplicates of machinery and of oil, leatherbelting &c., a large

quantity of which had to be constantly kept in hand in view of the large works which the Company had completed. The greater portion of these would eventually be debited to the machinery, and the balance would be carried to stores account. There was also a small item of R198-72 for firewood, which required no explanation. Coming to debts owing to the Company—R4,233,05—they were all good. He had now explained to them the accounts as far as possible, but if there were any particular items upon which any shareholder wished further information he would be very happy to give it as far as lay in his power. He could only say that they had expended their money as carefully and as economically as they could. They had provided everything of the most substantial nature, there was absolutely nothing scamped nothing shirked, and the machines which the Company had in its possession might safely be pitted against any other machinery in the east. While they had unfortunately been delayed in starting owing to circumstances which were quite beyond their control—for instance the Dock Strikes and other matters—there was the satisfaction of knowing that they started their Company at a very good time, and when machinery has very low. The same machinery could not be purchased now for a very considerable amount over what they had paid for it, so that in that respect the Company had been very fortunate. In every other respect the Company had also been fortunate. It had been most fortunate in its Manager. (Hear, hear.) It was not too much to say that they could not possibly have got along as well as they had done without the assistance given to them by Mr. Atherton (Hear, hear), and he thought the Company must consider itself most fortunate in having secured his services. There were many men who required to be looked after, but Mr. Atherton was not one of those: his whole mind appeared to be devoted to the business and prosperity of the Company, and he had no doubt the results of that devotion would be manifest at their next meeting and in their next accounts. There was no other particular matter which he had any need to dilate on, but if any of the shareholders had any particular point which they wished elucidating he would be most happy to do so. He begged to move that the accounts and the report of the Directors be adopted.

Mr. SPARKES had great pleasure in seconding the motion. He thought that the statement was very satisfactory. As regarded the construction of the Mills he was sure a great deal of care and skill had been shown. He had visited the Mills that morning, and had been very much pleased with them. The only item in the accounts which he thought was to be regretted was the small amount of capital subscribed, and the absolute necessity of borrowing, but he hoped that in time would rectify itself, and he was sure when the Company was in working order and they began to earn some money that a very different result would appear at the next meeting.

The CHAIRMAN, before putting the motion to the meeting, called on Mr. Mitchell, the Secretary, to make a few remarks, as he was naturally thoroughly conversant with the subject.

The Hon. W. W. MITCHELL said that he would endeavour to supplement the very full remarks of the Chairman. He had naturally taken a very deep interest in the matter from the beginning. The foundations of the Mills were begun on the 6th of Feb. 1889, the building materials were contracted for by the Company, and the building was actually done by Mr. Joseph Fernando, a native contractor. Anyone might satisfy himself by looking at the

buildings that the work had been honestly and thoroughly well done. It was not done by payment of a lump sum, but at so much per cube, so that the Company had only paid at a very reasonable rate of cost for the masonry work actually built up. Shipments of machinery, as they were aware, were received, the spinning portions from Messrs. Dobson & Barlow, and the weaving portions from Messrs. Dickinson & Sons, two of the very best makers, and he was assured by Mr. Atherton that there were no makers of machinery whose plant he would rather have than that made by these two firms. With regard to the iron work, were it not that Mr. Walker was present he might say a great deal more that was complimentary than he could say in Mr. Walker's presence, but he felt bound to say that more thoroughly honest, well done work was not to be found in the island than in the Wellawatta Mills. (Hear, hear.) The shipments of machinery began to arrive on the 10th of Sept., when the "Dee Dale" came in, and the last shipment arrived on the 25th of January last by the "Clan Mackenzie." Two fitters were sent out by Messrs. Dobson & Barlow; they were thoroughly qualified men and had been and were still closely engaged upon the work of fitting up the machinery. Mr. Harris, who was in the room, also joined them on the spot, coming from Japan, where he had been engaged for some length of time in putting up machinery in some new mills, and he had brought his large experience to bear on the work here. The services of Mr. Taylor, the weaving master, were also secured. He was a Lancashire man and had had large experience in Bombay as well as at home, and he had no doubt his services would be found very valuable. To Mr. Atherton belonged the largest share of credit for designing and constructing the Mills, and to his knowledge of makers of machinery and specialities, and his great ability generally as an expert, they were indebted for one of the most complete spinning and weaving establishments, with as fine an installation of machinery as could be provided, at a cost probably under that of any existing Mill of the size. The engine was first tried on the 31st Dec. 1889, and it commenced running daily from the 25th January.—The speaker then proceeded to say that what was called a "preparation" was now at work, and to describe the various stages and machines through which the raw cotton had to pass. A section of the Mills was now at work, he continued, and he was happy to place on the table that day the first-fruits of the Mill in the shape of a number of bobbins of yarn spun by the Company. With regard to labour they were not at all likely to find any deficiency—in fact the mill was besieged with applicants to be taken on. Female hands, he was happy to say, had also taken to the work very kindly. They were now engaged in standing round the machines, and were gaining so much confidence that they were ready to put their hands on them, though frightened of doing so at first, while some were even turning on and turning off the power, and were quite millhands already. They had also a large number of boys who would be found exceedingly useful. With regard to the rate of wages, he was glad to say, from what Mr. Atherton had told him, that they would be in a more favourable position than in Bombay: the rate of wages would be lower, and that would certainly give them a pull. They had obtained from India a number of men both for the spinning and weaving departments. It was desirable at first to get a number of trained hands so that they might teach others, and they had got a number of men to train the people on the spot and to

teach the local labour. In time perhaps they might be able to dispense with the services of these people if they desired to return to their own country, which was not at all improbable. To accommodate this labour to a certain extent they were now erecting lines or rooms for the workpeople on the Company's land, and probably this would result in time in a regular Milltown being erected there with, he dared say, a number of other buildings of various sorts attached to it. As regarded the cotton supply in the island they had had considerable quantities offered during the last six months, and a large quantity had come down from Jaffna; quantities had also been got from Batticaloa, and some had come from Anuradhapura the other day, the principal part being Tinnevely, but small quantities of Egyptian and New Orleans had also been brought. The weather had not been very favourable to a large outturn, but there had been some marked successes in some parts of the island. He was very hopeful that the result of the north-east monsoon planting would be much more satisfactory. Indeed they had a number of applications now from planters sending down small samples, asking what they valued it at, and saying their crop was now ripening. Some experiments on a large scale were being made, and he was aware of one estate in the Matale district where about 125 acres had been planted in the north-east monsoon. The results of this experiment would be placed before the public so that people might see for themselves how far planting cotton would pay. They had a short time ago the offer of 13 tons of cotton for delivery at Colombo during the next three months. That itself was a very encouraging fact, and showed that cotton in quantity could at all events be grown. He trusted that in course of time, with the encouragement which Government had been giving to its growth, they might see large portions of the island covered with cotton plants, if not with cotton plantations. He hoped that in course of time the northern part of the country would be opened up for cotton planting. It was undoubtedly a disastrous matter that Government should have withheld its sanction to the first preliminary steps in connection with the making of a Jaffna railway, but he believed that it was only a matter that was deferred, and certainly not put off altogether. The time would come, he hoped, when that line of railway would be made, and facilities would be given for intercourse with that part of the island, facilities for the transport of cotton and other produce to which they as shareholders would look forward with great anxiety. The only other thing which he would like to accentuate was the remark which the Chairman made in reference to the arrears of calls. It was exceedingly unfair to the shareholders who had paid their money at the right time when it was due, to see a long list of men who were perfectly able to pay and would not, and he was only sorry that their good friends of the Press, when putting the report in the papers, refrained from publishing the names of defaulters as well.

Mr. SPARKES said that there was just one question he would like to ask. When the Company was started they were told that the climate was supposed to be specially favourable for spinning yarns. He would like to know if that had proved to be the case, because the success of the undertaking was supposed to be in a great measure dependent upon that.

The CHAIRMAN said that Mr. Atherton, the manager of the mills, would perhaps be able to answer the question most satisfactorily.

Mr. ATHERTON said he could only say that all they had seen so far was promising. Mr. Harris,

however, knew all about the subject, and he would be able to give some information.

Mr. HARRIS said he had now been knocking about cotton mills in Lancashire, India, Japan and Ceylon for a good many years. He had seen some yarn tested that morning, and he had never seen anything like it before. From what he knew of cotton spinning he did not think theirs would be the only Mills started in Ceylon, or that the Wellawatta Company would not have to extend their operations. The climate was just what was wanted for yarns—the days were not too hot, and the nights did not get too cold. He had been in the mills at almost all hours of the day and night, and he never felt the same sudden changes that there were in Japan and even in England. A damp or moist atmosphere was really what was required for successful cotton spinning, and that was just what they had in Ceylon. He was sure that anyone who visited the Mills and understood the work could not have any fear of it not paying.

The CHAIRMAN said that they were much obliged for the opinions they had heard, but it was too early to speak with absolute decision on the subject. All experience, however, both written and verbal, went to show that the climate was eminently adapted for it. He might also mention that the Weaving Department, to which no allusion had been made, was being fitted up, and they quite expected it to be ready for work early in March, so that practically next month all the operations would have been taken in hand.

The motion was then put to the meeting and carried unanimously.

A SAFE INVESTMENT.

Mr. EDMUND WALKER wished to make a few remarks before the meeting separated, to enable the shareholders to realize what a safe investment they had in the buildings and machinery at Wellawatta. He would just mention one figure which would show how much more valuable they were now compared with the time at which they were put up. If they had to contract for the iron pillars which supported the roof, instead of having to pay £5 per ton in England, they would now be required to pay £8 5s, so that if they took those pillars and shipped them home to England the makers would be glad to give them back their money and pay all the expenses. When in addition to that the Company would begin, as no doubt it would in the next balance sheet, to write off something for depreciation, they would see what a thoroughly safe asset they had in the building, and it was particularly interesting to notice that, as buildings were always considered more or less of a doubtful asset.

Mr. ATHERTON said he might also mention that the spinning machinery would cost £2,500 more if it had to be purchased now than it did when the order was given.

RE-ELECTION OF RETIRING DIRECTORS.

The CHAIRMAN said that the next business before the meeting was to elect two directors in place of Messrs. R. L. M. Brown and W. Anderson, who retired.

Mr. SPARKES asked if Mr. Anderson would be returning to the country, and was informed that he would probably be back in April.

On the motion of Mr. RUDD seconded by Mr. J. De MEL the two retiring directors were then re-elected.

THE MANAGING DIRECTOR RETIRES, AS HE CONSIDERS THE OFFICE UNNECESSARY.

The Hon. J. J. GRIDLINTON said that while they were on the subject of directors, he wished to say

a word or two. On the formation of the Company it was thought desirable that there should be a Managing Director, and he was asked to take that office, not that he knew anything about mill machinery, for that he did not; he was in complete ignorance, but it was supposed that from his long residence in the country and from his professional knowledge he would be of assistance during the erection of the mills. He could not say that he had been of any assistance, or if he had been, it had been very little indeed. However, the object of that appointment having ceased, and the emoluments received from it from the beginning having been long since thrown up by him, he thought the office was no longer necessary, and though he did not desire until he was turned out to resign his office as a director of the Company, he did desire to resign his office as Managing Director for the reason that there was no necessity for it. They had their agents and secretaries and the work was conducted in the most able manner by his old friend Mr. Mitchell, under whose guidance he was sure everything would be conducted properly. He therefore resigned the office of Managing Director.

THE CHAIRMAN said that he had to thank them for re-nominating him as Director, and Mr. Grinlinton for his remarks, which were very much to the point. He felt that he ought to have anticipated him by mentioning the services which he had rendered to the Company. However, although he had resigned the office of Managing Director they would take good care that it practically came to the same thing: so long as he was a director they would take good care they got all the management out of him they possibly could, whatever his title might be. In thanking them again for re-nominating him to the office of Director he could only say that the conscientiousness which he had given in the past with his brother directors would, he was sure, be continued by all of them in the future.

ELECTION OF AUDITORS.

THE CHAIRMAN said that the next matter before the meeting was the election of auditors. He used the plural, because under the constitution of the Company the shareholders might elect one or more auditors. Now in view of the very heavy nature of the business and the great desirability of having the accounts most thoroughly audited and rendered beyond all deception it had been desirable to nominate two auditors to have what would be called a sort of continuity in auditing, so that in the event of one auditor falling ill there might still be one to carry on the continuity of audit from year to year, and the accounts continually audited on one fixed principle. With that in view they had nominated two auditors,—Messrs. S. T. Richmond and W. E. Taylor,—the latter of the Bank of Madras, and if the shareholders chose to re-elect those two gentlemen he believed their services were at the disposal of the Company. Mr. John Guthrie had also intimated his willingness to act as auditor. The appointment rested entirely with the shareholders.

MR. SPARKES asked if Mr. Taylor had had special experience as an auditor, and on being told that he was the accountant of the Bank of Madras, and had acted as an auditor in India, he had pleasure in proposing the re-election of Messrs. S. T. Richmond and W. S. Taylor as auditors for the coming year at a fee of R100 each.

MR. RAMALINGAM seconded the motion, which was carried.—The following was the Auditor's report:—

Colombo, Jan. 29th, 1890.

Messrs. Darley, Butler & Co., Agents and Secretaries,
Ceylon Spinning & Weaving Co., Ltd., Colombo.

Dear Sirs,—Having examined the books and accounts of the Company we have the pleasure of reporting, for the information of the Directors and Shareholders, that they are in good order and in accordance with the balance sheet.—We are, dear sirs, yours faithfully,

(Signed) S. T. RICHMOND & W. E. TAYLOR,
Auditors.

VOTES OF THANKS.

This completed the business, but before the meeting closed Mr. W. T. HOLMES moved a vote of thanks to the Chairman and Directors of the Company for their services during the past twelve months.

MR. J. DE MEL seconded, and the motion having been carried,

THE CHAIRMAN thanked them for the vote of confidence. He could only repeat that the care and attention which had been given to their interests in the past would be continued; in other words, they had so far been spending their money as profitably as they could, and they would now try to get as good a return for it as possible.

The meeting then terminated.

THE CEYLON PLANTERS' AMERICAN TEA COMPANY, LIMITED.

Colombo, Feb. 15th, 1890.

To the Editor,

SIR,—We now beg to enclose the additional correspondence from Messrs. Wattson & Farr and from Mr. Pineo, New York, and shall feel much obliged by your publishing them for the information of shareholders.—For the Ceylon Planters' American Tea Co., Ltd.,
DARLEY, BUTLER & Co.,
Agents and Secretaries.

An extract from Messrs. Wattson & Farr's letter dated New York, Dec. 27th, 1889.

We are much interested in the matter and are very hopeful that the Company will be successful and we propose to devote our best efforts to make it so.

The shop will be very attractive and we will at first concentrate our main efforts on this. If it succeeds we think that it is simply a question of time when the same principle can be extended to other cities. We have seen some of the great Jobbing drug houses of the West, and the seem much interested. Should we be able to induce them to take it up it would be an immense advantage gained. They tell us that in Germany Tea is sold by all the retail druggists and as the majority of the drug stores here are controlled by Germans, the idea will not seem odd to them.

We think it essential to the success of the Company that we should be provided with sufficient supply of Tea and think that a reserve stock of about 10,000 lb. should be kept here at all times.

Should the Company be successful we think it would be quite possible to have shares taken here to a considerable extent. As soon as the tea and the packing machine get here we will get actively to work and will keep you fully posted as to how the idea takes hold. We remain, &c.

R. Pineo, 140, Pearl Street, New York, U. S. A.,
December 26th, 1889.

Messrs. Darley, Butler & Co., Agents and Secretaries,
Ceylon Planters' American Tea Co., Ltd., Colombo,
Ceylon.

Gentlemen,—Your favor of the 9th ultimo, with enclosures as therein stated, reached me in due course, and for which you have my best thanks. I last had the honor of addressing you on the 16th November, when in Vancouver B. C. After leaving Vancouver I visited Winnipeg, St. Paul and Chicago, at each of which places I remained a few days en route to New York, where we arrived on the evening of the 30th November.

Messrs. Wattson & Farr, your special agents, received me most kindly, and I feel sure the Company has been exceptionally fortunate in having secured their aid and co-operation which are certain to prove invaluable.

Since my arrival in New York propositions to act as the Company's Agents have been received from firms and individuals doing business in San Francisco, Tacoma, Victoria, Vancouver, Winnipeg and St. Paul, but none from Chicago. These several propositions are now receiving consideration at the hands of Messrs. Wattson & Farr and myself and in due course the correspondence will be submitted to you. Encouragement of a non-committal character and much advice was tendered to me by every one I approached in the cities and towns hereinbefore enumerated, but with the exception of the Oppenheimer Bros. in Vancouver, no firm or individual was prepared or willing to give me an order, or handle Ceylon tea on conditions that would be acceptable to your Company.

All considered the time had come to introduce better and purer teas and that people's minds were exercised to an unusual degree over the tea question and moreover that we were about to enter the field at an opportune time when everything pointed to an increasing demand for pure tea, but they were unprepared to work the matter up at their own expense and risk.

At Mr. Murray's special request I visited him in Philadelphia with a view of arranging to secure his co-operation and take over his business, but the terms and conditions submitted by him were considered by Messrs. Wattson & Farr and myself as involving too great a demand on the present and future finances of the Company to warrant the purchase of his business at present.

Neither the tea nor Parnell's packer are yet to hand, and the non-receipt of the latter has prevented me from getting boxes made as the size of the boxes could not be determined, and until the exact shape and size are known I can neither order boxes nor get printing matter done.

Much preliminary, detailed work has been done to get matters in time to start the business as soon as possible after getting possession of the store, but the date upon which we shall be prepared to open the store is uncertain, and I fear we may not get to work much before February.

It appears to me matter for regret that elephants' feet, mounted and unmounted, were not sent with the curios.

Our search for a store ended in the selection of one on Twenty-second Street, one door from Broadway and the second from Fifth Avenue. It has a frontage of about twenty-five (25) feet on Twenty-second Street and its depth is about thirty-eight (38) feet, and below we have basement room large enough for present packing requirements. Enclosed is a sketch of its position showing its close proximity to the better portions of Broadway and Fifth Avenue. It would be difficult, I think, to find a more suitable situation or better surroundings. It is in the immediate neighbourhood of all the very best retail stores and where the ultra fashionable and wealthy ladies do their shopping, driving, and walking. The rent, \$4,360 per annum, will strike you as being extravagantly high, but Messrs. Wattson & Farr and myself do not consider it a high rental for the class of store in such a neighbourhood. Indeed, a few doors below, on Broadway, we were offered a small store at a rental of \$8,000 per year. The lessor of our store would not give us the option of keeping it on after the 30th April 1891 and peremptorily declined to allow any such clause inserted in the lease.

We think it will be possible to advertise the Company's business to greater advantage by having the store in this fashionable locality than if one, at a cheaper rent, had been taken elsewhere and the difference spent in some other form of advertising. We hope our action will meet your approval and we promise to curtail expenditure in advertising. When the place is fitted up we shall employ a young lady saleswoman and a porter or packer which, with the two natives, will form our entire staff at first.

The Company not having given a power of attorney to, nor being legally represented by anyone, the lease was made out in my name and payment of rent, quarterly in advance, was and is guaranteed by Messrs. Wattson & Farr. This lease will and can be transferred to the Company if so directed by you. The propriety and necessity of appointing a legal representative of the Company might be considered by the Board of Directors at their earliest convenience and their decision made known to Messrs. Wattson & Farr or myself.

We have concluded to dispense with a cut for the packet and will confine ourselves to getting up a neat, rich, tasteful paper box, and, in lieu of one brand and designating the different qualities, our determination is to have three or (if we handle green tea) four brands. Thus we shall avoid confusion and each brand will use different colours for the boxes and the lettering will be done with inks of varied tints. We have not yet settled upon the names, but think "Buddha" on a maroon coloured box, with white press matter; "Tiffu" on a gray box with red lettering; and "Bungalow" on a delicate rose tinted box with black printing will be the names we shall eventually use. You will receive a box of each brand when it is ready. Messrs. Wattson & Farr strongly recommend our packing orange pekoe and fixing retail prices at \$1.25 for orange pekoe, 90 cts. for pekoe and 65 cts. for pekoe-souchong. They also believe it will be to the best interests of the Company to handle coffee, and I therefore beg you will forward, by first opportunity, a few casks of Ceylon plantation coffee.

We are of opinion that the quantities of tea coming forward will not be sufficient to meet our requirements in a very short time, that larger shipments, in the proportion of two of Orange Pekoe, and three each of Pekoe and Pekoe-souchong should be forwarded, and that samples of our standard teas need to be sent to London and arrangements made there for supplying us, in case we are running short, or in any cases of sudden emergency. Our business would certainly receive a severe check and possibly be ruined if we were, at any time, unable to meet the demand which we believe will be, with the machinery we propose putting in motion, very considerably. Indeed, we think that the business will be limited only by your financial ability to supply us with tea and money to carry on operations. This leads me to remark that I do not feel in a position to make any advertising or other contracts until you have definitely settled money arrangements with Messrs. Wattson & Farr, who are, I imagine, disinclined to support me financially more than to a very limited amount as matters now stand. I desire to recommend that rather than purchase outright a Bill of Exchange you should send them a letter of credit for two, or three thousand pounds sterling and finally settle with them all financial questions.

Everywhere there is a growing taste for Ceylon and Indian teas, and, in the course of a few months, our sales ought to be fairly satisfactory.

Arrangements have been made for boarding and lodging the servants at 38 dollars per month, but whether they will prove satisfactory and permanent is open to doubt, as the rate is very low and may not be adhered to.—I have neglected to state that we do not get possession of the store until the 1st of January 1890, that in consequence of the high rental, our expenditure on advertising will be curtailed, and that the cost of fitting up the place need not be heavy.

In the course of a few days I shall submit to Messrs. Wattson & Farr a memorandum showing the amount of money expended on servants' clothing and board in Sydney, and also sums spent in travelling from San Francisco to New York. This account can only be supported by vouchers from hotels and partly for clothing supplied to the servants. The items for carriage hire, transfer of baggage, meals and sleeping accommodation on railways &c. cannot be supported by vouchers of any sort. This letter will be submitted to Messrs. Wattson & Farr before being mailed to you.

In conclusion: I beg to add that expenditure will be kept within the narrowest possible bounds and that every effort will be put forth by me to advance. The

interests of the Company with which my own prosperity and success are so closely identified. It must, however, be borne in mind that we are starting in business in about the most extravagant city in the world and that our success partly depends upon a bold front and a fairly liberal outlay.—I remain, gentlemen, your obedient, faithful servant,
R. E. PINEO.

MR. SHAND'S LECTURE AT THE SOCIETY OF ARTS.

The address read by Mr. J. L. Shand before the members of the Society of Arts cannot fail to further arouse the attention of people at home to the efforts made here in the growth of tea, as also to the intrinsic merit which our local product is possessed of. To Ceylon readers, as was to be expected, Mr. Shand's lecture contained but little that was not before well-known to them, and we do not propose therefore to devote space in this article to add to the remarks upon it which were made in our London Letter by last mail. What will be, however, of special interest to them, is the contribution afforded by Mr. Shand to a subject we have but lately had under our consideration, that of the disputation as to whether or not a reduction, or total abolition, of the present duty on tea would injure or improve the prospects of our local planters.

We have already, when writing on this topic, admitted the difficulty of correctly estimating what the effect of such relief being granted would prove to be. The line of argument adopted by Mr. Shand tends to show that there are other circumstances to be considered than the home financial easement. He contends that the abolition of the duty on coffee has been of ill-effect; that it has demoralized the trade; and he argues upon that presumption that the same result would inevitably follow a similar course if adopted in respect of tea. In this respect he has drawn attention to the extension of adulteration which followed the removal of the duty on coffee, mainly consequent, he asserts, upon the lax customs supervision of imports of that article induced by the discontinuance of collection of duty upon it. Mr. Shand has not left altogether out of view the injurious legislation which fostered this adulteration, but he assigns the foremost place among the several causes conducing to it to that which we have mentioned, that is the laxity of the customs inspection. Upon the statistics available he has shown how the consumption of coffee in Great Britain has fallen off as the result of that and the other causes contributing. That falling-off he maintains has been due to the demoralization of the trade, leading, as he asserts it has done to the great present difficulty in obtaining through the ordinary channels of supply a pure and satisfactory article.

Now similar adulteration to that which has been practised with regard to coffee would, Mr. Shand believes, follow any large reduction in the duty upon tea. In his lecture he pointed out that, were China teas so relieved, it would lead to there being exported from that country a large quantity of once-used leaf, rolled up and treated so as to present the appearance of freshly-made tea. At present the imposition of the duty prevents competition by such adulterated treatment. The price it is necessary to put upon it must stay its sale in the English market; while the practised eye of the customs officer during his inspection would at once detect the imposition. Remove these two safeguards, and according to Mr. Shand the home market would be flooded with such fraudulent preparations: Further, that gentleman is of opinion

that the maintenance of the duty is a direct encouragement to our planters to maintain a high standard of preparation, for it affords a protective element to the higher class of our teas. The view expressed by the lecturer on this matter adds a further additional light to the several aspects in which we have already discussed the question in these columns.

But on the very same day as that upon which Mr. Shand delivered his admirable address, a letter appeared in the *Times*, written by Mr. J. Alec Roberts of the Colombo Commercial Company, advocating a view in direct opposition to the arguments of the lecturer as well as to those previously advanced by Sir Roper Lethbridge in the letter he had previously contributed to the same journal. Mr. Roberts places his side of the question in a very alluring aspect, and it will doubtless go far towards convincing the British public generally of the soundness of the opinions he has expressed in it. But we think that on this side of the water, among men experienced in the matter, it will be held that the writer "doth protest too much." And, that Sir Roper Lethbridge is not prepared to accept Mr. Roberts' arguments any more than his figures, was shown by his rejoinder in *The Times* of the 25th ultimo. We must await the further development of the discussion and still more for news of Mr. Goschen's intentions; for after all, the varying assertions made leave this matter pretty much where we left it when last touching upon it. Nothing but the experience of time could show what the actual result would be from a removal of the tea duty.

THE CINCHONA BARK INDUSTRY IN JAVA :

MR. CHARLES BÖHRINGER'S VISIT TO THE JAVA
CINCHONA DISTRICTS.

Mr. Böhringer left Colombo on December 20th by the M. M. S. S. "Oalédonien" and returned by the S. S. "Iraouaddy" on 17th Feby. He arrived in Java just when the rainy season had set in, so he unfortunately had rain almost every day on his travels, though it usually fell in the afternoon. Batavia, Mr. Böhringer considers a very fine place: the houses of the Europeans are in Weltevreden (a suburb corresponding to the Cinnamon gardens of Colombo); they are all big and fine buildings, there are a theatre, public gardens, club, etc. In 1½ hour by rail the traveller reaches Buitenzorg about 800 feet above sea-level at the foot of the Gölö and Salak, two of the finest volcanoes in Java. Here are the botanical gardens with the residence of the Governor-General. The Gardens are smaller than Peradeniya, and contain a large quantity of specimens under the able management of Dr. Treub, who was kind enough to show Mr. Böhringer round. About three miles distant is the Agricultural Garden where the different kinds of coffee, cacao, indiarubber, tea, etc., are planted on a somewhat larger scale under shade of a kind of acacia. In Buitenzorg it rains nearly every day all the year through and usually in the afternoon from 4 to 6 o'clock. The Hotel Bellevue is very nicely situated on the banks of a river with a fine view of the two volcanoes. From Buitenzorg Mr. Böhringer reached Parken Salak Mr. Mundt's residence, after about 2 hours' drive by rail and carriage. The house is one of the finest country seats in Java furnished with all European comfort. There is a splendid view over the tea estate which produces about 800,000 lb. tea in a year. The tea factory is a model of a place on a large scale with abundant water power. Boxes are made on the spot. From there Mr. Böhringer went to Tjandjoer, the cen-

tre of the cinchona estates at about 3,000 feet altitude. He visited about ten estates in the neighbourhood. Most of the plants are ledgerianas, part of which are still very young. Cinchona seems to grow very well and gives a good average analysis. Bark is all packed on the estate. Another centre is North and South Bandong 5,000 feet elevation, and here Mr. Böhringer saw about 8 estates all in good condition. Mr. de Cuyper in Sukavana the administrator of one of the finest and most successful enterprises in the district told him that he had the pleasure of meeting Mr. A. M. Ferguson some years ago. This estate is situated at the foot of the Tankoebanprau, a celebrated double crater. The Government estates about 1,500 acres altogether present a fine sight, many old trees. The Government can afford to wait many years before cutting their bark. Private planters cannot wait so long of course, as they have to get money as soon as possible. Herr Von Romunde was kind enough to show me everything. Plenty of fine druggist quills are produced here from trees 20 years old. Mr. Böhringer believes that the Java Government can control the market for druggists' quills for some years to come, the production being very large. The Government has opened many thousand acres of new coffee land in the Preanger district where the leaf disease does not seem to do much harm now. The population of the Preanger district is not large: planters rather complain of being short of coolies. The Chinese seem to do the chief trade with the natives in all sorts of articles which they buy from the European merchants in Batavia. Chinese many hold appointments in the offices as cashiers, clerks, etc. We are promised an early copy of Mr. Böhringer's detailed report, which must first be sent to Germany.

TEA AND INVESTMENTS IN CEYLON.

(From Our Own Correspondent)

IMPORTANT MEETING OF THE COMMITTEE OF THE CEYLON ASSOCIATION—INDIAN AND CEYLON TEAS, AND THE ADVERTISING OF CEYLON TEA—THE TEA DUTY—RESOLUTION IN FAVOUR OF REDUCTION—MR. ROBERTS ON THE TEA DUTY—CEYLON FROM THE INVESTOR'S POINT OF VIEW.

LONDON, Jan. 31st.

What was probably the most important meeting yet held of the Tea Committee of the Ceylon Association in London was held on the 28th Jan. The Committee sat till quite a late hour, and we are told the discussions which took place during its sitting were of an unusually animated character. As the resolutions at which it finally arrived must be ultimately possessed of a very important bearing upon many matters connected with your present chief industry, it appears to be desirable that your readers should be informed of the names of those gentlemen by whom they received adoption. The chair was occupied by Mr. J. Whittall, and there were present besides Messrs. Rutherford, Scott, T. Gray, A. G. Stanton, J. Anderson, J. L. Shand, R. A. Cameron, J. Alec Roberts, W. J. Thompson, junr., T. Dickson, and Alexander Brooke.

The immediate object for which the meeting was summoned was the consideration of certain circulars issued by the Indian Tea Districts Association, and I fear the subject to be dealt with in this letter cannot be made clear to you unless an outline of the matter contained in those circulars is first given you, though to do so must necessarily tread upon the limit of my space. The first circular, dated Dec. 16th, 1889, stated that the Special Committee of the Association, after conference with leading brokers, had concluded that the causes of a depressed

tea market were:—

1st. The unnecessarily large number of separate breaks sent home by the gardens, thereby harassing the trade.

2ndly. The offering of an enormous quantity of tea for sale on a single day.

3rdly. The printing for sale of breaks of tea before the teas are actually ready for sale in the Warehouse, and consequent frequency of withdrawals from sale at the last moment.

With reference to the last cause, the circular went on to state that the brokers had been consulted, and that they had said that they had endeavoured by conferring together to prevent the difficulty, but that the merchants might well do more than they did to support their efforts. The Association Committee therefore recommended brokers to dissuade their principals from

1st. Printing the tea for sale before all the tea of each break are actually in the Warehouse, and have been bulked and worked.

2ndly. Bringing out fresh catalogues of tea to be sold on the last days of the same week in which catalogues are issued, when the total amount already advertised for sale appears sufficient, or more than sufficient, for the requirements of the trade.

The second circular, dated December 18th, 1889, embodied the resolution of the General Committee of the Indian Tea Districts Association upon their consideration of the foregoing resolution passed by the special Committee. This was to the effect "that the brokers be requested to meet once a week, and endeavour by mutual agreement to regulate the offering as far as possible in accordance with the demand at the time, and the members of the Association hereby pledge themselves to support them."

It was upon an invitation to the Ceylon Association in London to co-operate with that of India in the object of these several resolutions that the Tea Committee of that body met as above stated. So far as has been mentioned to me, although most of the members of the Committee had something to say upon the subject, there was little or no divergence of opinion as to the generally beneficial effect to be anticipated from the carrying out of those resolutions. The point to which argument was most directed—indeed mainly confined—was as to how far it might be necessary or desirable in the interests of Ceylon tea for the Committee to recommend present co-operative action with the Indian Tea Districts Association in the directions embodied in the two circulars. Upon this matter the following resolution was finally passed:—"That the Committee, having had under consideration the regulation of supplies of Ceylon tea to the London market, will be glad at all times to co-operate with the Indian Tea Districts Association, but do not see at present any necessity for making special arrangements in regard to Ceylon teas." This resolution was held to cover the whole ground opened out by those above given, and it furnished but a negative reply to the invitation made, though reserving of course the option of taking action whenever it might appear desirable to do so. What passed at the meeting is not sufficiently known to me to enable me to tell you why such a resolution was arrived at. As my own opinion only, it would seem to be probable that there was a feeling that the interests of Ceylon as represented at the Mincing Lane sales might be antagonistic to those of the Indian tea growers, and then too broad a commitment to joint action might possibly injure your island in its competition with the latter.

The further business dealt with by your Committee embraced consideration of a letter—I think from your Planters' Association, though of this I cannot write as of a fact—suggesting that steps should be taken towards further advertising Ceylon tea in the United Kingdom. Upon this subject the Committee resolved that it thought it would be advantageous to advertise in the United Kingdom as proposed, but think that if an opening could be found for effectual advertising in Russia, America, the Colonies and elsewhere, the benefit to Ceylon growers would be larger, and that any advertising, to be effective, must be done on a large scale.

It is not possible for me to tell you the nature of the communication which led to the adoption of this resolution. It may be presumed, however, that the question of providing the funds for giving effect to the suggestion, were it approved, was not omitted from it.

The final matter to which the Committee devoted attention was a letter received from Sir Roper Lethbridge on the subject of the tea duties, and dated January 26th. Into the matter of the discussion which followed its reading it is impossible for me to enter. It may, however, be assured that many divergent views were expressed upon this difficult subject; but that the majority of the members believed that the reduction would operate favourably may be gathered from the following resolution which received adoption. Resolved:—"That in the opinion of this meeting the reduction of the Tea Duty will be advantageous to the Tea Growers of Ceylon."

With that transcript may be concluded my notice of this important conference of your committee, but its closing business leads me to furnish you below with a copy of a second letter addressed by Sir Roper Lethbridge to the *Times*, one which was intended, of course, as a reply to that by Mr. J. Alec Roberts of which my last communication to you furnished you a copy. [Already given.—Ed. T. A.]

Now although myself disposed somewhat to the acceptance of the view entertained by Sir R. Lethbridge as to the probable effect of touching the tea duties it is out of the question endeavouring to follow the main argument he employs in the above letter, because he has, unfortunately, based it on the total of the "importations," and not upon the figures showing the home consumption. We all know how large a quantity of the tea imported is re-shipped to other markets, and in the face of such a fact comment upon Sir Roper's letter would be useless.

But during the week an opportunity occurring for me to see Mr. Roberts, this letter, and his own previously written one, were discussed. My view was expressed to that gentleman that Sir Roper had missed the real point of attack to which his (Mr. Roberts') letter lay open, pointing out that the assumption of 25 per cent increased consumption as the result of the superior strength of Indian and Ceylon teas could not be warranted by any known facts. Mr. Roberts, when replying to my observation, remarked:—"Well, I admit that the assumption you refer to is based on theory only. This correctness could only be proved by time, which would show us whether the poorer consumers would drink their tea stronger, or use less tea to keep their beverage down to the level of the China infusion they are used to. My own view is that if they have been in the habit of putting two teaspoonfuls into their pots, they will continue to use the same quantity although getting a better result, and in that case my calculation would hold good. If, however, they only put in

75 per cent of Indian when they used before 100 of China, in order to reduce strength, then, of course, I should be wrong. It's impossible to say what their practice would be with regard to using either Indian or China tea, and therefore any accurate forecasting of the result of touching the duty is equally impossible. Most of us agree with Mr. Shand that the weakening of customs supervision of tea imports would be a bad thing. But although asking for the removal of the whole duty, we only do so in the hope and expectation of a partial reduction. If sufficient duty is left on to insure continuance of customs supervision, it is all that we want. I certainly think the Government may lower the tea duty. You see it will add to the chance of their retaining the very powerful temperance vote, and as a concession to the poorer classes it will gratify a very numerous section of the constituencies. I may tell you that since my letter to *The Times* appeared, it has become apparent to me that the figures I quoted of increase of consumption from the *Public Ledger* must be in error. Other circulars than that I quoted from—although this was of one of the highest firms—give materially lower amounts, and therefore, until a reference by me has been replied to, the correctness of some of my assumptions must remain in doubt."

The following reference to Ceylon appeared in the *Investor's Guardian* of last Saturday:—

CEYLON, FROM THE INVESTORS' POINT OF VIEW, —On Monday night a paper was read at the Society of Arts by Mr. J. L. Shand, on the tea coffee and cocoa industries of Ceylon, and in noticing these, he dwelt forcibly on the rapid development of industrial enterprise in that island during the last decade. A leading feature in this growth of industry is the tendency to convert private estate property into Planting Companies. Formerly, the cultivation of tea in India was entirely, or nearly so, in the hands of Companies, whilst the reverse was the case in Ceylon. New Companies are fast absorbing private enterprises, and the time may come sooner than some anticipate, when the majority of tea plantations in the island may be owned by Limited Companies. Thus far, the career of tea Companies in Ceylon has been marked by uniform success. Dividends have been declared from 15 to 5 per cent., and scarcely a month passes but some fresh Company or enlargement of a Company is announced. Nor is it only for the cultivation of tea that Companies exist in the island. There is a Cotton Spinning and Weaving Company, three Gemming and Mining Companies and Syndicates, a Tobacco and Cigar Manufacturing Company, a Company for the growth of the Coconut Palm, a Wharf and Warehouse Company, an Hotel Company, several Ice Companies, a Steam Ship and Salvage Company, an Assembly Rooms Company, a Theatre Company, besides others, the names of which do not just now occur to us. All these facts emphasise the assurances given in Mr. Shand's paper of the undoubted expansion of Ceylon enterprise, and he is remembered, all of the above are the offspring of European energy, capital, and skill. In India, native capitalists have come largely to the front, but in Ceylon the rich natives remain pretty much in the old grooves, and when any public move is made it is for the formation of "Associations for obtaining Government employ."

TOBACCO SALES IN LONDON.—At an auction sale of tobacco in London on 30th Jan. a number of lots of Sarawak tobacco sold at very fine prices, such as 2s 11d, 2s 9d, 2s 7d, 2s 2d, 2s 1d, 2s, &c. Of course the fact that Sarawak is in Borneo is sufficient to tell in favor of the tobacco produced there. If Ceylon tobacco growers could get such prices they would be more than satisfied!

LAST YEAR'S TEA TRADE IN CHINA.

The *Shin Pao's* retrospect of the trade of the year ended 20th January says:—

The decline in the tea trade, we are glad to see, is engaging the attention of those who are most concerned, and there is every prospect of a return of the old prosperity as the improvements suggested are likely to be taken up in earnest very soon. Let us hope it will not be a case of 'going to look for the hound when the hare has broken cover,' or 'mending the fold when the sheep is lost.' The greatest failures this last season were black teas; green and Pingsueys did rather better, but by no means satisfactorily. The temporary boon of the previous season had made our merchants greedy, and many new tea-firms came into existence on the prospect of a continuation of it; but the high prices asked by growers in view of the immense demand and the difficulty of getting at money to purchase, baffled their hopes of a successful season. Native banks did pretty well, but the number of failures was so great that banking business on the whole must be considered to have done worse than the previous year.—*China Mail.*

PERAK TEA.

We (*L. and O. Express*) recently gave our opinion on the first consignment of Perak tea to this market. Our readers may be interested to know what a trade paper, the *Grocer*, says of this same shipment, which is as follows:—

Another tea-producing district is the latest novelty in the tea trade. Lately it was tea from Fiji, now it is the growth of Perak, situate in the Straits Settlements of the East Indies, where British capital and enterprise seem to have been employed with beneficial results. The first consignment to the London market has just taken place, and has consisted of an invoice of 76 half-chests from the "Perak" estate, where the tea has evidently been grown, cultivated, and manipulated by persons of considerable skill and experience in the industry. By expert valuers in "the lane" the quality of this experimental shipment is favourably spoken of, and on its being offered in public sale recently it found ready buyers at full rates—viz., Broken Pekoe at 1s 0½d., Pekoe at 11½d., Pekoe Souchong at 9½d., Souchong (a single package) at the same price, and dust at 6½d. per pound. Should the tea production of Perak materially increase, it will come into competition with Indian and Ceylon and in the course of time add to the general supplies for this country, and afford a wider and more desirable assortment for the trade to choose from throughout the year.

FISHING IN THE GANGES: GOOD SPORT.

A correspondent writes to the *Civil and Military Gazette*:—"There has been some extraordinary sport in the fishing line this cold weather at Baiwala on the Ganges, about six miles above Hardwar. A member of the Association, H. A. K., fished in one pool there from the 24th October to the 1st December, both dates inclusive, that is a period of 39 days. He caught fish on 33 of these days; he caught altogether 80 mahseer, weighing 2,000 lb., and a daily average of nearly 61 lb. for 33 days. The largest fish turned the scale at 64½ lb.; there was one of 46 lb., two of 44, one 42, two 40, one 39, two 38, two 37, five 36, two 35, two 34, two 33, one 32, two 31, and two 30, besides many between 20 and 30. The heavy fish first mentioned was 57 inches long, and had a girth of 30½ inches. The best single day's sport gave 7 fish, weighing 210 lb.; and there were two days on which 4 of 141 and 5 of 149 lb. were caught respectively. Other members of the Association had good sport in November too. E. S. killed 14 fish, weighing 296 lb., which included one of 43 lb. and one of 41. R. R. S. killed one of 35; A. W. got 3, weighing

76 lb. (one of 42), and M. K., 3 weighing 43 lb. Altogether 101 mahseers were landed, aggregating 2,450 lb., or about 24 lb. each on average. The above record, which is one of undeniable fact, will be interesting to all anglers as something quite out of the common. It has certainly been a most exceptional season."—*Pioneer.* [We should think so, as also that if such butchery goes on mahseer will soon be scarce.—Ed. T. A.]

TAXATION IN ENGLAND.

DUTY ON TEA COFFEE, COCOA AND TOBACCO.

In two articles on November 16th and 30th 1889, the *Economist* stated facts which, we confess struck us with amazement. The entire involuntary taxation of an average workman's family is now under 4½d a week. Here are the figures as given by a skilled economist:—

"Returns of working-class expenditure collected by the Board of Trade, and recently analysed in these columns, gave details of the outlay of 34 working-class families, comprising 180 persons, and with an aggregate yearly income of £2,493. The total expenditure of these families upon dutiable articles other than drink and tobacco is returned at about £107 per annum, and the taxation upon this expenditure amounts in round figures to £32. In other words, each of these 34 families, consisting, on an average, of five persons, and with an average income of £73 a year, contributes to the Imperial Treasury in the shape of taxes on tea, cocoa, and coffee about 18s 6d a year, or 4½d a week."

It may be said, quite justly, that to exclude liquor is unfair, because the workman wants his beer to make up the proper stimulating quality of his food. Very good; we should concede that at once, though Sir Wilfrid Lawson will not; and how then does the matter appear? This is the answer:—

"The total expenditure of the 34 families upon dutiable articles other than tobacco is returned as follows:—

	Expenditure for Week.	Equal to Annual Expenditure of
Tea.....	£1 11 4½	£81 11 6
Coffee	0 5 6½	14 8 2
Cocoa	0 4 2½	10 18 10
Beer	0 15 2½	39 10 10

Taking the price of tea at 1s 6d a lb, that of coffee and cocoa at 1s a lb, and that of beer at 4d a quart, this annual expenditure represents a consumption of 1,088 lb of tea, 288 lb of coffee, 219 lb of cocoa, and 593 gallons of beer. Let us now see what the duties chargeable upon this consumption amount to. The statement including the estimated consumption of tobacco is:—

Quantity Consumed.	Rate of Duty.	Amount of Duty Payable.
Tea..... 1,088 lb	6d per lb	£27 4 0
Coffee .. 288 lb	2d per lb	2 8 0
Cocoa 219 lb	2d per lb	1 16 6
Beer..... 593 gals.	2½d per gall.	5 7 0
Tobacco .. 270 lb	3s 2d per lb.	42 15 0
Total		£79 10 6

To this total some slight addition should be made on account of the expenditure on dried fruits, which are subject to a small duty. With this addition, the total amount of taxation may be set down, in round figures, at £80. And this is the total contribution to the Imperial Treasury out of incomes amounting in the aggregate to £2,493. In other words, the proportion of taxation to income in the recorded cases amounted, on the average to only 3-2 per cent. This is equal to about 7½d in the £, and the evidence of the returns which the Board of Trade has collected is thus to the effect that the whole taxation of the working classes amounts to not very much more in the £ than the classes above them pay in Income-tax alone."

Now, how much further are we to go in this direction? We can understand a Radical thinking that only property ought to be taxed; but then, let all property be taxed, the workmen's as well

as the millionaires'. Or we can understand a financier saying that he reserves taxes on the whole community—taxes, for example, like those on sugar, tea, and beer—for times of emergency; but then, let that policy be avowed and discussed, and the workmen brought clearly to understand it. At present the theory is that all should be taxed, roughly speaking, on the principle of equality; but recent legislation has carried the facts far beyond that point. The well-to-do now pay in direct taxes nearly as much as the handicraftsmen do in all their taxes, and then pay their indirect taxes over and above. It is time that these facts should be made clear in Budget discussions, and that we should at least know the central idea upon which Parliament is proceeding. If the well-to-do are to pay "ransom," as Mr. Chamberlain once put it, they ought at least to have the credit of paying it in the popular eyes.—*Spectator*.

QUININE AND THE EPIDEMIC.

If the "influenza" has disturbed trade generally, it has also stimulated one or more special branches. Notably the consumption of quinine has been increased, and the stocks of dealers and druggists everywhere reduced. Some considerable deliveries have also recently been made to America. All the same, there is no fear of famine prices. Messrs. Lewis and Peat, of Mincing-lane, in a circular just issued, say that the available stocks of quinine are too large—too much is manufactured for these times of "peace," and importers have so regularly supplied the auctions with cinchona each fortnight, that there has been little chance of a permanent or serious advance in values. A halfpenny is about the extent of the rise, the quotation being 1s 3½d per ounce in bulk. It is extraordinary how the price of quinine has fallen in recent years. A dozen years ago English sulphate of quinine was quoted 13s, now it is 1s 6d. German was then 12s, now it is 1s 3½d. The price of bark for quinine was unprecedentedly low last year. As there were large speculative transactions, it would be interesting to know whether the "bulls" reckoned on the epidemic.—*Pall Mall Budget*, Jan. 31st.

THE WEATHER PLANT.

To the dissipation of the claims of Professor Nowack of Vienna to be able to foretell not only meteorological phenomena but actually earthquakes and explosions of fire damp in mines, by observing the movements of the leaves of a plant, a whole number of the "Kew Bulletin" is devoted. The German Professor, who ought to have been born in pre-scientific times, actually took out a patent for his supposed discovery. It was tested by the eminent botanist, Professor Oliver, who describes as below the creeping plant so common in the jungles of Ceylon, especially in the drier portions of the island. We once cultivated it, for the sake of its pretty purple flowers and especially for the little red and black seeds, which are strung as necklaces and used by goldsmiths as weights. Those seeds have strangely different effects when swallowed and applied sub-otaneously, as Professor Oliver shows in his description, which we quote:—

The plant *Abrus precatorius*, Linn., is a well-known tropical weed. Originally a native of India, it is now widely dispersed in tropical regions, including Mauritius, the West Indies, &c. It is a leguminous plant, with the habit of a shrubby climber. In the case of the plants used by Mr. Nowack the young rapidly-growing shoots were cut in before requiring any support. Thus the production of lateral shoots and foliage was stimulated.

The seeds of *Abrus precatorius* are well-known as "crab's-eyes," and are used all over the world for decorative purposes. In India they are called *rati*, and are largely used by goldsmiths as weights, each weighing about 1½ grains. It is stated that the famous Kobi-noor diamond was first weighed by the *rati*, a word which is indeed supposed to have given origin to the jeweller's carat (Kérat, *Arab*).

The powdered seeds are harmless when eaten, but rapidly produce fatal effects when introduced beneath the skin even in small quantity. They are used criminally in India in "Sui" poisoning, the object being to obtain the skins of the poisoned domestic animals. The poisonous action is due to the action of a protied *Abrin*.

The leaves of the plant are two to three inches long, with 10 to 15 pairs of shortly stalked leaflets. The texture of the latter is very delicate and membranous; the surfaces glabrous.

At the point of insertion of each leaf on the stem is a slightly swollen joint or *pulvinus*, and each leaflet is provided with a similar small secondary pulvinus at its point of insertion on the main rachis. The rachis as well as the leaflets perform considerable movements both vertically and laterally on their pulvini. It is with these movements that the bulk of this report is concerned, as on them Mr. Nowack bases his various weather prophecies and barometric charts.

The leaves are arranged on the stem *alternately* with for the most part a divergence of ½, but since in its development a leaf generally bends round through an angle varying from a few degrees to as much as 90°, it is found on an adult shoot that the leaves point in various directions. They spread themselves so as to obtain the most favourable illumination. This point is of some importance and will be referred to later on.

We have only to add to the above description that the roots of the plant have all the properties of liquorice. We need scarcely say that botanically, meteorologically and seismically, Professor Nowack's pretensions to foretell by means of this interesting but not miraculous plant were refuted. Professor Oliver's conclusions we quote:—

In conclusion, I contend that all the movements exhibited by the leaves of *Abrus precatorius* depend on causes not so far to seek as those suggested by Mr. Nowack.

The ordinary movements of the leaflets, of rising and falling, are called forth in the main by changes in the intensity of the light. In a humid atmosphere they are more sluggish than in a relatively dry one. In other words when the conditions are favourable for transpiration the movements are most active.

The position for snow and hail is connected intimately, in the cases that have come under my own observation, with a spotting or biting (by insects) of the leaflets, and is not due to any other external factor.

The position for fog and mist and for electricity in the air is probably due to the disturbance caused by varying light, the rhythmical movements of the leaflets being temporarily overthrown.

The position indicating thunder and lightning I take to be pathological from its tendency to recur on the same leaves.

Daily movements of the rachis constitute a periodic function in this as in many other plants with pinnate leaves. The regularity of these oscillations is considerably influenced by both light and temperature.

How important severely careful and disinterested experiments are, can be judged from the claims previously made on behalf of Professor Nowack and his prophesying plant, by his English agent in a letter to the *London Times*, as follows:—

Professor Nowack contends, (1), that the weather plant is an electro-magnetic plant; (2) that if it is placed, corresponding with a magnetic compass with its north branches towards north, in an apparatus of his own special, but, after all, very simple, construction, and is therein grown and cultivated in the special and simple manner described by him; it will then, and only then, cease to be susceptible to the influences of its im-

mediate habitat; (3) that its sensitiveness to atmospheric and electric influences can then, and under such conditions alone, be thoroughly controlled, and may then be turned to practical account for forecasting the local weather, with truly marvellous precision, 48 hours beforehand, and likewise earthquakes, or subterraneous disturbances, both at a distance and locally, with respectively three to eight days' previous notice.

Any number of weather plants placed under such conditions will behave alike. Such is Professor Nowack's experience, which extends now over more than 34,000 different observations with hundreds of plants, and is, all in all, a matter of the deepest scientific study. In Austria the merits of the plant have been fully recognised by a great many who had originally approached the matter with the utmost disbelief and ridicule. The Archduke Reiner is a firm believer in the plant's merits, and has shown Mr. Nowack much encouragement in his work, and whole townships, agricultural unions, farmers, &c. have furnished testimonials to like effect. The observatory of the Austrian Tourists' Club, on the Sonnenstein, at an altitude of 1,511 metres, in the Styrian Alps, well known to many English tourists, which supplies the various branches of the club with weather forecasts during the season, has now for already over a year, discarded both aneroid and ordinary barometers for that purpose, and depends for its forecast upon the weather plant alone. The earthquake at Stolac, in Bosnia, on the 10th inst., which was so clearly and accurately forecast by the weather plant as early as the 2nd inst. at noon, and was thus mentioned in the "Times" of the 5th inst., must, moreover, be a conclusive proof to even the most sceptical that forecasts of great importance can be reliably ascertained by the aid of the weather plant.

So much for ordinary human and even quasi-scientific credulity. We may add that Professor Oliver's observations were made on plants provided by Professor Nowack. In the new edition of Clough's Sinhalese Dictionary the plant we have been noticing is mentioned under the word *Masha*, thus: "jeweller's weight, colloquially *olinda-wel*, weight about 17 grains troy."

PLANTING IN HAPUTALE.

RAIN—COFFEE—TEA—THE CHIMNEYS BLOWING "INCENSE TO THE SKIES"—THE LATE MR. GLENNY'S BUILDINGS—THE MARRIAGE OF A BUDDHIST PRIEST—THE MEDICAL ASSISTANT—OLD DAMBAWINNA. R. M.—POLICE—THE GOVERNOR'S VISIT—CATTLE MURRAIN.

February 12th.

Since my last notes, I have extended my ramble from Golconda Hospital as far as the farthest estate at the west end of this district. The rains of the 31st ultimo and at beginning of this month must have been much heavier towards that side, as I found the cart road seriously damaged in two places before reaching Haldummulla town, and pioneers were repairing the damages, but although the water seems to have gone over the two well built bridges at Batgoda they were not damaged. The rainfall on an estate at that end was 4.40 inches on the 31st ultimo and 4.95 in. on the 1st instant, continued more or less up to the 5th instant, but has been fine since. Today the clouds are gathering all round and a small shower is passing as I write. There was pretty strong blowing of wind especially during the nights on the other side and about the Pinnaketiya Pass, and my hat was near being blown away on a voyage of discovery in to the lowcountry. All over the other side, wherever there was any good coffee remaining, the trees on the estates were crowded with blossom spikes which should have opened by this time and the result should be a good coffee crop "next year." Tea was looking well, but not flushing particularly wherever the quality or "jat" of the bushes was of an inferior description. Some tea of high class jat in the Kalupahana Valley was looking superb, and no doubt the good almost virgin soil and climate of this valley are just the thing for the growth of tea. The chimneys of the two factories at Berragalla and Needwood were blowing "incense to the skies" and working, but I had

no time to look in and see the friends of the "new generation" and new product at work. May their chimneys smoke for ever! J. A.

COOLIES ON TEA GARDENS.—A contemporary writes:—"Mr. Fletcher has been elected Honorary Secretary of the Terai Tea Planters' Association, in succession to Mr. Gordon, who is going home. At the same meeting, a unanimous vote of thanks was accorded to Mr. Gordon, for his valuable services while Honorary Secretary of the Association. At the same meeting, it was agreed that the offer of a special police force for the protection of coolies marching by the route recommended by Mr. Fletcher from Chota Nagpore to the Western Dooars and Terai was necessary to the interests of the district. This resolution is a sensible one; as there is no doubt whatever as to coolies from Chota Nagpore being very frequently—indeed, wilfully—misled as to their destination by the agents of coolie contractors from Assam, Cachar and Sylhet. The Dhangurs do not know very much about geography, and they are undoubtedly often 'personally conducted' to other tea districts, while they were fancying themselves en route for the happy hunting grounds of the Darjeeling Terai and Western Dooars.—*M. Mail.*

OUR EXPORT OF CARDAMOMS during the current season has been exercising the wits of leading local authorities as to where all the supply comes from that continues to find its way through the Colombo Customs. The great cardamom districts of Ceylon are generally believed to be "Rangala, Nitre Cave and Medamahanuwara," the north-eastern group of planting districts; and a careful detailed estimate for each estate in this division and making allowance for some from the Knuckles, only shows a total outturn of 120,000 lb. for the current year—that is from 1st Jan. to 31st Dec. 1890. How much more should be added for the rest of the country is the question? Well, from what we know of the country and planting, elsewhere, we should feel inclined to limit the total shipments to about 200,000 lb. with the foregoing information before us. But when we turn to the recorded exports for the current commercial season and note that 201,409 lb. have been shipped between 1st October last and 13th Feb., against 131,000 lb. in same period last season, we fear that our previous estimate for the whole year 1st Oct. to 30th Sept. of 300,000 lb. will be under rather than over the mark, and that the shipments for the calendar year will not be much less?

THE FINANCES OF THE DUTCH EAST INDIES.—A report on the budget for Netherlands India, which has lately been published by the Foreign Office shows an estimated revenue of £10,677,072 and an expenditure of £11,708,355 or a deficit of £1,031,283. The expenditure however, includes £774,417 for the construction of Government railways and the establishment of telegraphic communication between Macassar and Bandjermassin, while there is also an increase in the estimate for the navy. The increase in revenue is due to a higher estimate of the returns for the sale of coffee, but there is a decline in the estimated returns from cinchona and tin. The deficiency will be met, if necessary from the surplus for 1887 which amounted to £2,091,652 and was the largest surplus since 1867. On the whole the financial result of the past six years is a great improvement on the previous six. Between 1878 and 1883 there were deficits every year except one amounting in the aggregate to £4,388,359, to meet which a loan was raised in 1883. On the other hand in 1885, 1886 and 1887 there were surpluses amounting altogether to £2,428,200.—*London Times.*

COFFEE, CORN, AND PIMENTO IN JAMAICA.

Cultivation of coffee is extending immensely in the district. Prices have been very good this year and every one has gone to planting coffee, and this is the staple product of the district. A great amount of corn is also being raised, and has been selling at an average of three shillings a bushel this year.

The people have no good method in their cultivation or in preparing coffee or corn for the market. They are just as primitive in this respect as they ever were. They work out the land entirely and never use any means to make it more productive. The lime that is washed down from the hills acts in some slight measure as a fertilizer. It would, no doubt, be very difficult to use a plow in many parts of the mountain districts, the formation being in a great degree of honeycomb rock, which crops up through the soil.

The people have no knowledge of properly preparing coffee and corn for market, and what little is done in this respect is of the most primitive description. None of the corn is kiln-dried, and the coffee is greatly deteriorated from lack of proper care in the manufacture. We think that what is most needed is a central factory to which the people could bring their coffee and corn, the factory purchasing the coffee in berry and the corn just as gathered. The growers know nothing about hulling, washing or sizing, etc., of the coffee. We think the people would be glad to avail themselves of a factory if one were established. As it is now everything is so primitive, in cultivation and manufacture as in the days of Abel, perhaps more so.

—From a notice of Brown's Town in "Jamaica Gleaner."

Again with reference to St. Anne's Bay:—Crops, we found that banana cultivation was extending considerably, a fair estimate placing the increased area in this fruit over last year at two hundred acres. Coffee is also being extensively planted in the Parish, especially in Dry Harbour Mountain district. Prices have been very good, and trade in this product active. Pimento crop has been short. Some trouble has been experienced in getting the bananas to a market, and but for this there would be more grown. The sugar crop this year has been rather small, mainly on account of the seasons,—too much rain. One estate only made half a crop, and we understand several will lose money this year. No estates have been thrown up recently, but there are only nine in the parish now.—*Jamaica Gleaner*.

We noticed that corn is not often grown on land by itself, but is put in among other crops. We heard of yields of from twenty to forty bushels of corn per acre, and two crops a year, in this district—and yet we import a very large quantity of corn from abroad to supply this thinly populated fruitful country.

There are three or four places in the district where are kept three or four hundred boxes of bees, but nothing at all scientific or systematic in the keeping of the bees is attempted. Everything is primitive and rude.—*Ibid*.

CEYLON OOLONGS.

Messrs. Rucker & Bencraft report in their circular of the 30th ultimo:—

We sold a small invoice of desirable Oolongs at an average of 1s 5½d.

The Oolong tea above referred to was marked B. E. 11½ chests No. 1 550 lb.

12½ " " 2 540 " and was offered for public sale on the 27th Nov. in Colombo, and taken out for want of bidders, the only offer being 30 and 40 cents! it was ultimately sold at 50 cents per lb.

It is evident that Ceylon buyers have yet a deal to learn as to the value of Ceylon teas, a similar quality was sold on the 4th December at prices which stopped the manufacture!

QUININE AND INFLUENZA.—Our London correspondent writes by this mail:—"Quinine has been largely purchased. A sketch in *Punch* this week refers to it." The sketch in question is entitled "Refreshments in Vogue," and represents a waiter at a ball asking a lady: "Quinine or anti-pyrene, my lady?"

THE TALGASWELA TEA COMPANY, LIMITED.

GENERAL MEETING.

The annual general meeting of the Talgaswela Tea Company of Ceylon, Limited, was held yesterday afternoon at the offices of the Company, No. 5, Baillie St., Fort, Colombo. Mr. T. C. Owen (Chairman of the Company) presided, and the following directors and shareholders were present:—Messrs. Shelton Agar, Geo. K. Deaker, T. W. Hall, G. C. Walker, H. P. Rudd, Eric S. Anderson, Walter Agar, G. D. Dick, G. W. Suhren and A. Schulze (Secretary). The following shareholders were represented by proxies:—Messrs. James Mitchell, E. G. C. Mitchell, O. L. Scott, T. Labouchere, H. Pasteur, R. S. Patry, T. C. Sanderson, J. J. Cater, J. G. J. Cater, H. P. Cater, C. A. Cater, A. Kuhn, A. L. Wylie, G. A. Borrett and G. L. Deaker. The minutes of the last meeting were read and the report (as published in the *Observer* on the 11th instant) was taken as read.

ADOPTION OF THE REPORT.

The CHAIRMAN, in moving the adoption of the report, said that there was very little to remark upon, but it might interest them to know that the cost of developing the estate up to last year had been R192 per acre, and by the estimates for the current year the total cost would be R224 per acre, after which they trusted that no further capital expenditure would be needed. The figures for the cost of opening the estate were after allowing for a deduction from the capital of the value of 1,300 acres of forest land on the estate. At the end of 1891 it was hoped that they would be in a position to pay some dividend. Later, when the estate was in bearing, if they could get 500 lb. of tea per acre, and if they could obtain 45 cents per lb. they would get a return of R60 per acre, which would enable them to pay a dividend of 20 per cent. They could not say this for certain because it would be difficult to know what the price of tea was to be the year after next. The next thing was that all labour was cheap. On the estimate for the last year R3,000 were saved under this heading, and the cost of weeding in the present year's estimate had been put down at 30 cents per acre per month. In the accounts before them nothing had been taken off for depreciation in buildings or machinery because these had all been erected so very recently, but a liberal amount had been taken off the capital account for tools, carts &c.—about 25 per cent. He did not think there was anything else which called for notice, but he laid on the table the estimates for the coming year, which perhaps the shareholders would like to see.

Mr. DEAKER seconded the motion for the adoption of the report.—Before putting the motion the CHAIRMAN said that he was told that there was a gentleman present who had recently visited the property of the Company, and the shareholders would be glad if he would give them his impressions.

Mr. DICK thought it would be presumptuous of him to offer any remarks, as he was not a planter, and he could only tell when a tea plant looked healthy about as much as he could when a turnip did at home. He, however, had visited the place, and stayed 24 hours there. He was accompanied by a friend who was a Kelani Valley planter, and he always referred to him to qualify any impression that was made upon his mind during his visit. They first saw the factory, but he was not qualified to make any remarks about that. They then walked through the tea fields, and saw the different "jāts," as they called them. The plants appeared to him to be in healthy condition, but he asked

his Kelani Valley friend what he thought of the place, comparing it to the Kelani Valley. His friend seemed to hesitate about answering him at first, and then he said that the tea was not as advanced as the Kelani Valley would be. Then Mr. Broadhurst chimed in that the tea plant did not come to a head so rapidly at Talgaswela during the first two years of its growth as in the Kelani Valley, but that afterwards it shot ahead splendidly. Another remark of Mr. Broadhurst's had also struck him, viz. that the low-lying ground on the estate might very well be planted with Mauritius grass. The labour on the estate interested him very much. Sinhalese labour had its advantages and its disadvantages. One advantage was its cheapness. It required quite a different management to Tamil labour, and Mr. Broadhurst had explained to him the difficulties of working with Sinhalese labour. It, however, appeared to him that Mr. Broadhurst was the right man in the right place, as he appeared to know them so thoroughly, but he had come to the conclusion that if they were entirely dependent upon Sinhalese labour they might find themselves "up a gum tree." The two great advantages were that the expense was less, and they had no lines to provide.

Mr. SHELTON AGAR did not think it was quite fair to compare the Kelani Valley two year old tea with the Talgaswela tea, because the Talgaswela tea was only 15 to 16 months old, and the very oldest there was only 18 months, so that it would scarcely be fair to compare two year old tea to 15 months old tea. The tea on the northern portion of the estate, to which allusion had been made, was practically only six or eight months old.

Mr. DIK said that he would like to make another remark in reference to the water power on the estate. Mr. Agar was much interested, as they all were, in getting as much water as they could, and there was a plan to get water from a stream which flowed through the north of the estate. It seemed to be an open question whether the level of that water would enable them to do so or not. He would like to know what proportion of the power could be supplied by water even if there was an available supply.

Mr. SHELTON AGAR said that at a previous meeting they had decided that the water power would be of great use to the Company, and they should get as much done by means of it as they possibly could, supplementing what was required by a steam engine, working the steam engine when the water supply failed. Mr. DIK agreed that that seemed to be the most practical way.

The report was then unanimously adopted.

RE-ELECTION OF DIRECTORS.

On the motion of Mr. HALL, seconded by Mr. WALKER, Messrs. T. C. Owen and G. W. Suhren were re-elected Directors of the Company.

ELECTION OF AN AUDITOR.

The CHAIRMAN said that the next business was to elect an auditor for the coming year. Mr. Guthrie had applied for the post, and the Secretary informed him (the Chairman) that Mr. Guthrie had been of great usefulness to him during the past year, and had taken a great interest in the accounts. He had, therefore, pleasure in proposing his re-election.

Mr. HALL seconded, and the motion was carried.

SHOULD AN OUTSIDER BE ASKED TO REPORT ON THE COMPANY'S PROPERTY?

Mr. HALL said he had been asked by a gentleman whose proxy he held to propose that an outside report be made on the Company's property. In asking this the gentleman whose proxy he held desired to express no doubt at all on the management of the estate, or on the visiting agent's report, but he thought it would be to the benefit of the Company in many respects to have an outsider's report. He had not much to say, as they had already

discussed the matter in Committee meeting, and he would simply leave it in the hands of the general meeting to decide whether an outsider's report would be of advantage to the Company or not.

Mr. WALKER had pleasure in seconding the proposal.

Mr. WALTER AGAR proposed as an amendment that no outsider was required. If any of the shareholders considered it necessary there were very able men amongst themselves who could go down to the estate and report for the satisfaction of the Company. If a shareholder wished that an outsider should do it he could take an outsider with him, but at the present stage of the Company's affairs he did not think that it was advisable that they should incur the expense of asking an outsider to go down. He did not think there was any object to be gained by it, and they would only be wasting the Company's money. So far as he knew they were all satisfied that things were going on very well indeed — [Mr. HALL: Quite so.] — and he proposed that no outsider be asked to report on their affairs at present.

Mr. SHELTON AGAR seconded the amendment. In his opinion the Company's affairs were in a very satisfactory condition. They had 716 acres under tea, instead of 500 as was originally proposed, without having had to spend more money than they were prepared to spend on 500 acres. If there were any cause of complaint he would be the first to call for an outsider's opinion, as he was very largely interested in the Company, and represented individually the largest number of shares of anyone in the Company. He thought that if an opinion were wanted in regard to the estate, and what was being done there, that they had men amongst themselves who were quite capable and quite honest enough to give an opinion irrespective of any personal feeling in the matter. At the present stage he did not think it would be advisable to have an outsider's report on the estate.

The CHAIRMAN said that he must support the amendment proposed by Mr. Walter Agar. He did not think that at the present moment there was any necessity whatever for bringing in an outsider to give them an opinion. If the shareholders would like other opinions than those of the Visiting Agent there were many amongst them who, he was sure, would give a fair and unbiassed opinion, which would carry every weight.

Mr. HALL desired it to be distinctly understood that he was not making the motion on his own behalf. He was quite satisfied with the report, especially as it was backed up by Mr. Diak and his friend the Kelani Valley planter.

Mr. WALKER said that he supported Mr. Hall because he had heard many remarks to the effect that it was desirable in the interests of the shareholders that they should have an independent report on the property. He also thought it was advisable that they should have an outside report.

The amendment was then put to the meeting: 7 voted for it and 4 against, so that the amendment was declared carried.

The meeting concluded with a vote of thanks to the chair.

The Visiting Agent's report was laid on the table, and the following are extracts of interest therefrom:—

Seed account planted in nurseries runs as follows:—

Planted in Nurseries.	maunds	
4½ from Messrs. D. Edwards & Co.	Single.	
3½ Sandison's	Indigenous.	
10 Alston, Scott & Co's Indian Manipuri	do	
5 Kirrimittia	do	
—		
23		

Summarising the whole extent of seven hundred and sixteen acres under tea, the account for seed and plants

would approximately stand as follows :—	
716 acres at 3,500 per acre...	.. 2,506,000
Supplies, say 650,000
	<hr/>
	3,156,000
Plants at present in the nurseries estimated at 250,000	
	<hr/>
	3,406,000

Roughly speaking three and a half million plants have been raised from 253½ maunds tea seed purchased during 1887, 1888, and 1889.

This gives an outturn of about 13,000 plants per maund, which may be considered as fairly successful. Arecanuts planted throughout the ravines and along boundaries, etc. are doing remarkably well. A few coconuts planted close by the New Bungalow also seem to thrive well.

Mining operations for Plumbago and other Minerals were being carried on at the time of my visit by Mr. W. M. Young. He is prospecting on his own account with the understanding that for three months he is free to take all he can find, after the expiration of which time he gives a 1-10th share to the estate of any minerals, etc., that are found on Talgaswela. Mr. Young in the course of his mining operations has come on several minerals which he tells me will pay well. I have asked the Superintendent to forward samples to the Secretary to be placed before the Directors at their next meeting. Plumbago has been found on many portions of the Estate; but the indications are not sufficiently pronounced, owing possibly to the pits not being sunk deep enough for me to give a decided opinion. Mr. Young however appears very sanguine that plumbago in paying quantities will eventually be found.

There is a craze at present in the district for Plumbago digging which has raised the rates of daily wages for able bodied men, but I do not attach much importance to this, as Talgaswela is surrounded on all sides by villages, and I feel confident that all estate works can be carried out at low rates. There has been a saving on several field works during the past year.

THE PLANTERS' ASSOCIATION OF CEYLON.

THIRTY-SIXTH ANNUAL REPORT. PLANTING PRODUCTS:

TEA—COFFEE—CINCHONA—CACAO—CARDAMOMS—
TOBACCO—COTTON.

TEA.—The cultivation of this product still continues to increase, and the area under tea may now be put at 200,000 acres as against 187,000 last year. The past season is remarkable as having caused at one period a panic, dissipated almost as soon as created, by the as steady rise as there had been fall in price, and the greater firmness in the market. During the months May-June, the average price fell till during June it reached as low as 8½d to however at once beg in to rise till in September it reached 1s 2d, and in November it was 3d higher. The average for the year ending September was, notwithstanding the unprecedentedly low prices ruling during the earlier portion of 1889, only 3d lower than the previous year, or 11d as against 11½d. This temporary fall proved however a blessing in disguise, as it caused cost of production to be more seriously looked into than ever, and the more sanguine to cease planting operations on soil that was not suitable. Your Committee hopes that the lesson then taught may not be forgotten. The low rates ruling and the increased quantity going into consumption, helped also to further displace China Teas, and your Committee congratulates you on the excellent position of your staple, a position, so far as human foresight can foresee, it is likely to maintain. Total Exports for season ending September 30th, 1889, reached 32,516,682 lb. as against 20,755,779 lb. for the previous season. Your Committee has pleasure in drawing your attention to the large increase in Exports to markets other than that of the United Kingdom. For the season ending September 30th, 1888, 646,258 lb. were exported to foreign markets whereas season ending 30th September 1889 shows exports to markets other than that of Great Britain

1,572,004 lb. The Australian market took 1,134,156 lb. as against 479,626 lb. the previous season, America 49,770 lb. as against 28,247 lb., India and Eastward 295,433 lb. as against 23,746 lb. the previous season. The Ceylon Planters' American Tea Company Limited, has recently been floated for pushing your Teas in America and other foreign markets, and your Committee trusts it may meet with the success it merits, still further aid in distributing your Teas over the world and thus lighten the home market.

The Exports for the year 1st January to 31st December 1889 were 34,345,752½ lb. as against 23,820,472 lb. for the year 1st January to 31st December 1888. A statement courteously furnished by the Hon'ble the Collector of Customs which is of much interest as giving authoritative data of the export of Tea to the United Kingdom and to the other Markets is annexed to this Report.

COFFEE.—During the twelve months there has been a great falling-off in the exports of Coffee. The Chamber of Commerce returns for season 1887-88 showed the exports to be 186,295 cwt. of Plantation and Native. In season 1888-89 :—

Plantation ..	78,433 cwt.
Native ..	8,007 "

Total .. 86,440 "

This gives a deficiency of almost one-third from the Export of the previous season. Green bug which caused so much consternation a few years ago is undoubtedly less prevalent than formerly, especially in those parts where it first appeared and from a consensus of opinion it would seem to be less virulent in its attacks than it was at first. This has encouraged many, in view also of the high prices now ruling to decide upon keeping some of their remaining coffee in cultivation and not allowing it all to make way for tea. Leaf-disease shews little abatement, although there are many who hold the opinion that it is not so severe as formerly. It is highly probable that in some districts coffee may still receive the attention that it has had in the past. In further confirmation of this there are some now who believe that if well selected shade of certain kinds had all along been grown amongst the coffee bushes, in every way the coffee would be more permanent and in support of this opinion shade of approved kinds is being planted in good coffee in several places, especially the drier coffee districts of the island.

The Exports for the year 1st January to 31st December 1889 were 88,986 cwts. as against 137,798 cwts. for the year 1st January to 31st December 1888.

CINCHONA.—The exports of this product during the year have continued on a smaller scale than for some years past. Notwithstanding the heavy reduction in exports the price of bark has ruled at a very low average in the home markets throughout the year viz. 1½d to 1¾d per unit, but towards the end of the year a slight improvement has taken place. At these prices it is needless to say that Cinchona cannot be planted and grown at a profit in Ceylon, except in possibly one or two favoured spots, and the cultivation all over the Island has been given up, to a very large extent, in favour of Tea. The existing stock of bark in the Island is rapidly decreasing, and in a very few years Ceylon will be able to supply but a small proportion of the World's consumption of Quinine.

The Exports for the year 1st January to 31st December 1889 were 9,455,641 lb. as against 12,482,817 lb. for the year 1st January to 31st December 1888.

CACAO.—This product has again regained its export average; the last year being favourable on account of the well apportioned rainfall. The area cultivated is not being increased, simply because land suited to its growth is not procurable.

The Exports for the year 1st January to 31st December 1889 were 18,849 cwts as against 12,231 cwt. for the year 1st January to 31st December 1888.

CARDAMOMS.—The area under this cultivation has been steadily maintained during the past year by planting of small acreages on estates where it has been found Cardamoms can be successfully grown. It is a capricious plant, and only thrives and fruits in certain favored localities, and at an altitude of 2500

to 4,200 feet above sea level. The old Malabar variety is nearly extinct, and only the Mysore kind is now ever planted. The market value of Cardamoms fell considerably during the latter end of the past year.

The Exports for the year 1st January to 31st December 1889 were 466,163½ lb and 1 pkge. as against 281,925 lb for the year 1st January to 31st December 1888.

TOBACCO.—A considerable extent of land was planted with this product during the past year with fair success and much knowledge of the conditions necessary for the production of a "wrapper" leaf has been acquired. During the coming season the cultivation will be extended and with the experience and knowledge now available, your Committee anticipates that Ceylon tobacco will ere long have its merits recognized in the market and become a valuable subsidiary product.

COTTON.—The successful establishment of a cotton spinning and weaving factory near Colombo has drawn attention to the cultivation of cotton in Ceylon. Both by Europeans and by Natives it is being tried more or less experimentally in various parts of the Island and in some cases with considerable success. Valuable addition has been made to the literature of the subject, notably by the prize essays published in the "Ceylon Independent." The cultivation is simple and inexpensive, while under favorable circumstances the yields are quick and very considerable. Insect pests and a wet climate are the two difficulties which will probably prevent any large cultivation on estates throughout the planting Districts. But it seems probable that in the drier parts of the country the enterprise will be profitable to the Native in his chena and to European Companies in large plantations.

STATEMENT OF TEA EXPORTED AT COLOMBO, TO THE UNITED KINGDOM AND TO THE UNDERMENTIONED COUNTRIES, FROM 1ST JAN. 1889 TO 31ST DEC. 1889, REFERRED TO IN PARAGRAPH OF TEA.

THE HOME TEA SALES.

Particular attention should, we think, be given by all locally interested in the growth or the shipment of tea to the Resolutions passed by the Tea Committee of the Ceylon Association in London as given in our London Letter by last mail. As regards combined action with the Indian Tea Districts Association, it would seem that the Committee representing Ceylon tea interests do not regard it to be necessary, at all events for the present, though ready to co-operate at such times as it may usefully do so. But while we feel we may safely leave the determination as to any such action to those who represent us at home, we would desire to direct attention to the final conclusion at which the Indian Association arrived; because there can be no doubt that much might be done here towards assisting the home trade in its desire to better regulate the course of the tea sales in Mincing Lane. The conclusion reads:—"That the Brokers be requested to meet once a week, and endeavor by mutual agreement to regulate the offerings as far as possible in accordance with the demand at the time, and the members of the Association hereby pledge themselves to support them."

Now how far, or by what methods, our local shippers can contribute their quota of support in this matter, should, and doubtless will, be the subject of careful consideration by the Planters' Association, which will doubtless have received by the same mail, full details from its home agents. It has long been felt, we believe,—indeed we recollect the prominence given by Mr. J. L. Shand to this point at one of the earlier meetings of the Ceylon Association in London,—that the over-weighting of the market at individual sales is the main cause of much of the irregularity in price obtained for Ceylon teas. It appears to us desirable that local shippers should give to those to whom they intrust their home sales a considerable amount of latitude as to placing their shipments on the market. If this is not done—if, in their desire to obtain an early financial return, they confine their home agents within too narrow limits of action, it is not possible that the brokers can exercise the power of discrimination which seems to be so much desired. Of course, a change might mean the incurrence of delay inimical to those quick returns, the importance of which to most of our planters and shippers cannot be overlooked. But, on the other hand, if such delay should result in improved prices being obtained, and a more regular condition of the market, this advantage might well be set against the undoubted disadvantage of a deferred return, and it would probably be found in the long run to more than counterbalance the latter.

Our suggestion in this respect must certainly be acknowledged to run counter to the desire lately manifested, to secure the shortening of the term of "prompt." The action then contemplated had for its incentive a quicker return to the grower and shipper of the results to their industry and outlay. For very good reasons, to which we referred when that particular question was under discussion, the views of the home referees in this case, were deferred to. Now, as it would seem, a further concession is recommended in the interest, not, be it recollected of the home trade, but in that of the producers in this island. It will be for the Planters' Association in consultation with the Chamber of Commerce perhaps, to settle how this can be made without resulting in serious inconvenience; but we think that all will see how carefully considered the matter has been in London, and will therefore allow that the decision taken has been arrived at solely in the interest of the producer. Several of the other points embraced in the Resolutions of the Indian Tea Districts Association Committee have reference solely to the convenience of those who conduct or attend the sales in London; but indirectly no doubt these also have a bearing upon our tea-growing industry, and should not therefore wholly escape the attention of our readers.

The final Resolution of the Tea Committee of our London Association dealt with the question of the beneficial or ill results to be expected from an entire or partial remission of the duty on tea. It will be seen that it records the view that a reduction would certainly be beneficial; and in spite of some doubts which are shared, as we know, by a not inconsiderable number of those who have given consideration to the matter, we may well be content to accept the conclusions arrived at by so expert a body as is that Committee. Sir Roper Lethbridge appears to have based some of his chief arguments upon incorrect data, and that being the case we must necessarily refuse to give weight to them. On the other hand, the public opponent of Sir Roper's views, Mr. Roberts of the Colombo Commercial Company, has also had to admit the possible incorrectness of some of his data. But

we may rely upon it that full consideration was allowed during the discussion of this matter in London for both inaccuracies, before the Committee adopted the Resolution to which it has pledged itself. The practical point now has reference to Mr. Goschen's intentions. The latest intelligence is not very favourable to the prospect of the tea duty being touched at all; but we may see "the unexpected" occur and a reduction in the duty by 2d proposed and carried.

CEYLON UPCOUNTRY PLANTING REPORT:

LIPTON ON CEYLON TEAS—PRICES FOR BLENDED TEA—VIRTUES OF TEA IN EARLY DAYS—TEA-MAKERS AND A LADY'S IDEA ABOUT IT—TOBACCO NURSERIES.

February 17th.

When Lipton, the ham and butter man, went in for pushing Ceylon teas at home, he made a grand advertisement of it. Cart-loads of tea chests paraded the streets preceded by brass bands, and the newspapers told how Mr. T. J. Lipton had paid the biggest sum for tea duty—several thousands of pounds—that had been paid since the tea duty scare just before Budget day, about five or six years ago. He was in the market about the end of April last year when our teas were very much depressed, and the prices he offered to sell at were startling. A "magnificent Indian and China blend, pure and fragrant," was to be had for 1s 2d a lb.; a "specially selected Ceylon, China, and Indian blend" sold at 1s 6d; while the "extra choicest Indian and Ceylon blend" cost 1s 9d. From a friend I have got a sample of the 1s 2d tea, which I send to you; and all I can say is that I am glad the name of Ceylon is not associated with it. I hardly knew what to test it against, but tried congou, and even then it came out very badly indeed, yet it is entitled a "Magnificent Indian and China Blend."* What the "Extra Choicest" 1s 9d lot was like I have now no curiosity to know: but I incline to think that it too will be "cheap and nasty" like the blend named the "magnificent."

From present tea drinkers to the tea drinkers of the past is an easy transition: in reading the late Mark Pattison's Essays I stumbled the other day on one of those early believers in the virtues of tea. The old French scholar, Peter Daniel Huet was one of the first to adopt the use of the beverage in France, and has nothing but high praise for the benefits he received. It appears he *boiled* his tea, and this is what he says of the results:—"The experiment succeeded so much beyond my hopes, that I seemed to have acquired a new stomach, strong and active and no longer subject to indigestion. On this account tea rose so high in my esteem that I scarcely suffered a day to pass without drinking it. I derived from it the further benefit that its salutary leaves, with their benign vapours, swept the brain, thus meriting the title of brushes of the understanding." Now from *boiled* tea those results are not at all bad; the old scholar although perhaps not quite up to the best means for getting a good cup of tea was still a long way ahead of the mother of a sailor of our own nation, who in those early days had got from her son a pound of the fragrant high-priced leaf. She was said to have boiled it also, and after throwing away two or three dirty waters, served up the leaves, and she and her invited guests ate them on bread!

Visitors to the island are often struck with things, which are wholly unnoticed by those who dwell

* Messrs. Somerville & Co., to whom we sent the packet, report on it as follows:—"Broken tea; present London value 6½d; Colombo equivalent at exchange, 1/5½ 29c. Dry leaf greyish ragged uneven and flaky leafy. Broken tea, rather stinky. Liquor thin, common. Infused tea dark and irregular."—Ed. T. A.

therein. The numerous advertisements in our daily papers of "tea makers wanted" led a lady visitor to come to the conclusion that Ceylon was prominently the land for the spinster, her idea being that the advertisement represented bachelor planters advertising for wives! This is about as good as the ancient joke of their being so many "single-he's" in Ceylon as to make it the paradise of the unmarried lady; and better a good deal than the new edition, which had it that Ceylon was the land of the one-eyed, as the native was but a single-ee. It would be hard to beat this last for badness. [Getting a 'mon soon' in this eastern land is quite as vile!—P. D.]

Tobacco growers say that nurseries put in at the beginning of the year, and planted out at the beginning of the S.-W., succeed very much better than when the nurseries are made in the S.-W. and planted out in the N.-E. It seems that this also is the experience of tobacco growers in Sumatra.

PEPPERCORN.

BLUE GUM.—The extensive growth of the blue gum in and about Ootacamund, has had the effect of reducing the price of this fuel to R2 a handy load. The contractor will tell you that this rate only pays when the wood is purchased green and just as it is cut down. There is so much moisture in it that 2,000 lb. of dry wood cannot be sold for the same price without a loss on the transaction.—S. of I. Observer.

QUININE.—A big Yankee reckoning is found in the following paragraph:—

Boston consumed a ton of quinine pills (the *Record* of that city declares) during ten days of the influenza epidemic.

A ton of quinine would equal 26,880 ounces or nearly 13 million grains. This would give 35 grains for each man, woman or child in Boston for the 10 days! An average of 3½ grains a day over all the population is rather too much, though there can be no doubt that the Americans understand the value of quinine in a way that the people of England and Europe have yet to learn.

THE ENEMY OF TEA referred to in a note in our issue of yesterday is, we find, the tea bark louse, *Aspidiotus* sp., regarding which Mr. E. E. Green wrote last year as follows:—

"I consider this to be the most serious enemy of the tea that I have yet noticed. I have received specimens of tea infested with this insect from several different districts. Though from its habits it is not easily detected, I believe it to be present in enormous quantities on every estate, where it is responsible for many hide-bound unproductive bushes. In the most injurious form of the pest the insects are crowded together on the older stems, each individual concealed by a thin scale which most accurately imitates the bark upon which it rests. So close is this resemblance that at one time I thought the insect was actually living beneath small blisters formed in the outer layer of the bark."

The remedies he proposed were as follows:—

"I would suggest the removal of these old diseased stems wherever it can be effected without spoiling the bush. After pruning they should be either burned or completely buried. It is for pests of this family that the Americans so largely use kerosene emulsions, sprayed over the trees. In the case of pruned tea bushes this treatment could be more thoroughly and economically applied than in that of thick coffee; and I believe that the beneficial results would amply repay the outlay. I hope shortly to be in a position to give statistics of the cost of application of the emulsion. I am expecting the loan of a small force pump with nozzles specially designed for the purpose of distributing the liquid in a fine mist-like spray. The actual cost of the emulsion would be very little, as the kerosene is highly diluted with soap and water."

Correspondence.

To the Editor.

VINE LEAVES.

DEAR SIR,—Can your botanical referee say what is the matter with some vine leaves (sent under separate cover) and what doctoring is required? The leaves belong to the black Hamburg variety, and although the plants grow well, the foliage on arriving at maturity dies off like those sent.

VITIS VINIFERA.

[Our referee reports:—"I cannot say what disease the leaves are suffering from, and am unable to suggest a remedy. They arrived in too dry a state for successful examination." Our correspondent should send some to Peradeniya which is nearer him than Colombo, and probably Dr. Trimen could aid him.—Ed. T. A.]

"MATAGALLA" BRAND TEAS.

London, Jan. 3rd.

DEAR SIR,—Our correspondent in Colombo has forwarded us a cutting out of your valuable paper (23th November 1889 date) in which there are some remarks regarding our Matagalla Ceylon Tea. It appears that some person living in or near Cheddard had received one of the ½ oz. samples we supply gratis to our customers with first orders, to distribute to the best families in the district in which his shop is situated. This sample he forwards to you for inspection. Now from the date of this order in our books, the particular customer must have received the sample over 7 months ago, consequently it had been at least 6 months in the little paper sample bag. No wonder therefore it tasted "papery and smelt flat, &c." As you have been at some trouble to get an opinion upon our Matagalla Ceylon Tea, which could not in the nature of things do us justice; may we ask you in common fairness to submit the two samples we have today forwarded you by Parcels Post to the same test and examination? These have been taken promiscuously out of our present blends and are average samples of our quality. We venture to hope you will do us the justice to give them into the same hands as those who tasted the little ½ oz. sample previously. As an old Mincing Lane tea taster of 28 years' standing I early saw the value and merit of Ceylon tea, and by "all appliances and means to boot," have sought to popularize the teas from the island. Indeed our firm was one of the earliest to put Ceylon teas before the trade until at this moment they are sold in almost every town and village in England.—Apologizing for this trespass on your time, and thanking you in anticipation, yours truly,

S. T. FRANCIS (Alfred Smith & Co.).

P. S.—We have sent you also the stationery hand-bills, show-bills &c., so that you may see the style of the getting-up.

[The tea samples which have now reached us are indeed very different to those referred to in November. Those before us and which we have tried do credit to the name of Ceylon and afford good value for the money. We are also pleased to learn that Messrs. Alfred Smith & Co. have done so much to promote the sale of Ceylon teas and we have included their Firm in the list published in our *Overland Observer*. The analyst's report attached to the packages sent us is as follows:—

To the "Matagalla Tea Co."—This is to certify that I have executed a careful Microscopical and Chemical Examination of the "Matagalla Ceylon Tea." It is a natural and pure Tea, containing one-third its weight of Extractive matters, very rich in the NUTRITIVE, NITROGENOUS PRINCIPLE CHARACTERISTIC OF ALL GOOD TEAS. The Volatile constituents in the Tea give to its infusion a REMARKABLE DELICATE TASTE AND A BEAUTIFUL AROMA. . . . It is a first class Tea. (Signed) ED. V. GARDNER, F. A. S., M. S. A., Professor of Chemistry, London.

We are only beginning to realize in Ceylon the immense importance of the Tea "Package" Trade in Britain and it is with reference to the dealers who blend and sell pure Ceylon teas, that the great advantage of a reduction of the tea duty say by 3d, is seen. This would enable really good Ceylon teas to be sold in 1s 6d packages with profit to all concerned.—Mr. Francis we understand, fixed on "Matagalla" as his brand with no other idea than to have a distinctive name for his Ceylon package teas.—Ed. T. A.]

AN ENEMY OF TEA.

Kandy, January 31st.

DEAR SIR,—By post I am sending you in a tin box "poochies" that are becoming rather troublesome on my tea bushes. They are curious little "beasties," and pierce the tea leaves, as you may note, rather *badly*! Can you kindly give me information regarding these creatures, and say whether they are likely to increase to a large extent? As, if there is any likelihood of this, steps should be taken at once to have them eradicated.—Yours faithfully,

SHELTON AGAR.

[Our entomological referee reports:—"The insects are the larvæ of some psychid moth, but I do not know the species, and under ordinary circumstances this family is not very injurious. But only two days ago I received specimens of a much larger species from Matala, with a note saying that they had almost entirely defoliated about 100 trees in a patch, and that the insects were swarming there. It is one of those cases that show how an insect, harmless under ordinary circumstance, may from some unknown cause suddenly increase to an injurious extent."—Ed. T. A.]

WESTERN AUSTRALIA: A SANATORIUM FOR CEYLON AND INDIA.

The S. S. "Orient," Feb. 1st, 1890.

SIR,—Will you please allow me space in your columns to call attention to the advantages which Western Australia now offers to Europeans in Ceylon as a Sanitarium and place for the education of their children. The first consideration is that of suitability of climate. All the south-western part, from Perth to Albany (as the town at King George's Sound is called), is far out of the tropics and yet not so far as to offer an injuriously extreme change. At Perth in 1888 the lowest and highest shade readings of the thermometer were 34 and 105 respectively. Albany being 250 miles south the readings would be lower. I want to submit to your readers whether this is not a sufficient change to be recuperative and yet not extreme enough to leave disastrous results. It should be remembered that ours is a dry heat, and in that respect a further contrast to the climate of Ceylon. The next matter of importance is proximity. The magnificent steamships of the Orient Line and of the P. & O. Company bring Albany within 10 days of Colombo. The ocean to be traversed offers less dangers to the traveller than that between Ceylon and England. There is not even the Australian Bight to be crossed. Some time can be pleasantly spent in the picturesque and prosperous town of Albany. The ever-changing scene on the jetty; the come and go of those "floating palaces," the mail steamers, twice a week; excursions on and around the bay; drives to the uncleared bush and to the virgin forest; all offer charms to the languid European-Ceylonese. The circle of pleasure and invigoration at Albany being exhausted, the tourist can take a ticket for £2-15-3 and travel to Perth, 340 miles distant, by the newly constructed Beverley-Albany line, which is a continuation of the Government Railway. New scenes are opened to view, new vistas

of forest, of park-like lands, of sandy downs covered with short shrubs that in their season bear flowers of every hue, and anon in summer, a glimpse of a dried-up salt lake is obtained gleaming through the foliage like the driven snow. The first day's journey ends at Beverley;—stop-over privileges can be had, and the tourist can rusticate for a day at this little town. Here he may botanize, and gaze in wonder on trees that shed their bark annually instead of their leaves, whose smooth trunks tower upwards, and are crowned with small, thick, shining leaves arranged in parasol-like groups. An hour spent by moonlight within 200 yards of Sewell's Hotel, amongst the salmon gumtrees,—their tall, gaunt forms seen in sharp outline, the arched vault above studded with countless stars, the moon hung in queenly splendour lets fall her softened rays until the leaves glisten as if coated with burnished silver,—will afford a spectacle not easily forgotten. Twenty miles farther on is the larger town of York, environed by hills, chiefly dominated by Mount Bakewell. For the ascent of this mount another day may be taken; and then the journey continued to Perth. Grassy and tree-covered hills will be seen on either side of the line; until about mid-day the mahogany forest, last seen near Albany, is re-entered. The many blackened trunks, the charred stumps, the fallen branches, and almost bare ground, all tell how fiercely the bush fires rage through these forests in the summer months. Then the descent to the valley of the Swan River begins. The valleys deepen, the hills draw nearer, huge boulders of granite lie within reach, the denuding action of the past is more apparent; the line curves, now running over the foot of a hill and anon overlooking a gorge, and presently the taller buildings of Perth—16 miles distant—outline themselves against the horizon. Guildford is only just ahead, embosomed in the valley. Passing through it, the train makes a pause in sight of the river Swan, and by 2 o'clock the tourist will find himself in Perth.

Perth is situated at a bend of the Swan River where it widens out into lake-like proportions. At the extremity of Perth the escarpment of Mount Eliza overlooks a narrow part, beyond which the river widens into great reaches—offering full scope for yachting, whilst the shallower Perth water gives facilities for rowing and smaller sailing boats. Here is infinite variation, from the placid bay when all is glassy and idle, to the foam-crested mimic waves of our stormiest day. Excursions down the river, drives out of town, visits to the port of Fremantle, 12 miles away, life at the Clubs, and so on, will afford recreation and give new strength to the health-seeking tourist. Where time is very important all that I have described can be done whilst the ship is going to and returning from Sydney. It can be re-joined at Albany, and in a few more days, "Home, sweet home," is made all the more pleasant by this sight of a new country—a trip within the means of some who cannot afford to think of England.

Great as are these advantages, I believe our colony offers still greater. An anxious problem, ever presenting itself to the European-Ceylonese, is that of minimizing the evils attendant on the upbringing of children. The present necessities involve the separation of parents and children for some years—robbing the parents of half their joys, and depriving the children of advantages for which no efficient substitute can be supplied. Another unsatisfactory feature is that no process of acclimatization is going on. The contrast in climate between Ceylon and England is so great and the stay in England necessarily long, so that the children become Europeanized in constitution when they return to the

parental home or estate, they have probably formed European alliances, and their children are no more able to withstand the peculiarities of the Ceylon climate than they themselves were; the partings and anxieties have all to be repeated in each succeeding generation.

I am sure that it is well worthy of inquiry whether these evils would not be greatly mitigated, if children were sent to Western Australia instead of to England. Proximity is here an important factor, communication being quicker and admitting of an occasional visit home or of parents to children—the flames of parental and filial affection being fed anew. Then the climate being healthy, though not so greatly differing in temperature as England does, would surely inure the constitution to the climatal conditions of subsequent life. Alliances would probably often be made with Australians, who being accustomed to heat might not be much affected by transference to Ceylon. Is it too much to assume that under such conditions succeeding generations would be less and less affected injuriously, and finally become so acclimatized as to remove the necessity for separating children from their parents to avert an early grave?—Yours faithfully,

WILLIAM TRAYLEN. PERTH, W. AUS.

THE COCONUT LEAF TROUBLE.

Colombo, February 7th.

DEAR SIR,—I was glad to see Dr. Trimen's report on the so-called coconut leaf disease. This was known to coconut planters of standing for many years, and the only successful remedy is liberal cultivation.

The "Examiner" correspondent could have learnt this if he had only taken the trouble to forward a few of the diseased leaves to the Director of the Botanical Garden instead of writing so much to that journal insinuating that others, who differed from his opinion, were only doing so, to prevent the value of their estates being depreciated. Now, I think seriously that the "Examiner" correspondent is due to the worthy doctor a fee for the valuable hints he has given as to cultivation, but he might have gone further and advised him to select soil more adapted for coconut growing, as in doing so, he would be less troubled with coconut leaf disease.—Yours faithfully,

UNMITIGATED BOSH.

A NEW FOREST CLEARER.—An invention has been patented in New Zealand which, if it does all that is claimed for it, will make clearing of forest land a much more easy matter than it is now. It consists in a composition with which trees can be poisoned, mingling itself with the sap, and circulating through every branch and leaf utterly destroying the life and rendering the standing tree in three months time dead and rotten and so highly inflammable that when fired, it burns away literally root and branch, for the fire creeps even down the roots into the ground consuming them so thoroughly that the land can be ploughed afterwards. It is available also for old stumps thus doing in a month what nature takes years to accomplish. The process of inoculation is simply the boring of a hole about 6 inches into the tree with an inch auger, filling it with the composition, and afterwards plugging it with cork, touch-clay or other suitable substance. The composition has had several trials and is stated to have done effectual work in all cases; in one instance 700 acres having been cleared with it, every tree, it is claimed, being successfully dealt with. It is also said to be very inexpensive.—*Indian Agriculturist*. [But what is the wonderful substance?—Ed. T. A.]

A TREMENDOUS SHIPMENT OF TEA.

The "Dacca," which sailed last Tuesday for London, took over 590,000 lb. tea.

This caps, we believe, any previous shipment of Ceylon tea in one bottom by over 100,000 lb. tea.

TEA IN INDIA.—It is reported that several firms in Calcutta have had under consideration the experiment of more largely employing natives in the management of teagardens. The idea appears to be that men in the position of overseers or managers acquainted with the language and habits of the coolies will be able to manage them more easily than men whose knowledge of the language is very imperfect, and whose patience is not equal to the requirements of the position. It is thought that if the coolies are assured, of good treatment, and that they will be taken care of, and their safety assured, they would readily take service in the gardens, and the labour difficulty would thereby be solved.—*Madras Mail*, Feb. 11th.

THE PRICE OF QUININE.—It is very annoying to learn from Mr. Byers that after trying quite a large number of chemists, both in London and elsewhere, his experience of the prices at which the invaluable prophylactic and tonic is still retailed, runs from 4s to 16s per ounce! This is monstrous, even though the "influenza" had created a special demand. How can we ever expect the consumption to increase in Europe at such prohibitory rates for an article that can well be sold with a handsome profit, even in grains, at less than 2s an ounce. What is Mr. Rivers Hicks about with his penny boxes of quinine pills? Can he not get the grocers and other retailers to take up the sale in the United Kingdom? We have had several inquiries lately from England as to where cheap quinine can be got.

TIMBER GROWING.—A Western Dolosbage planter sends us the following useful note:—"The timber question is an interesting and important one, and I wish to add my mite of information. I have just been measuring one of my *lunumidella* trees, planted in July 1873 at an elevation of 1,700 feet, with this result:—Length of clean stem to where the tree branches 29 feet; circumference at the bottom 9½, middle 7½, and top 6 feet. To appearance the tree has not grown much the last year or two, but no doubt the wood is acquiring value in maturing. Two years ago I sawed planks out of similar trees for ceiling my bungalow, and they answered first-rate. I should say it would do well for tea boxes. For firewood, it would not be of the lasting nature of hardwood trees. I would not recommend its being planted amongst tea, as I think it a surface feeder; but for boundaries and waste places at a medium elevation it deserves attention. It is well to keep in mind the advice, 'Aye keep sticking in a tree, they will be growing, Jock, whilst ye are sleeping.'" We well remember seeing and admiring the trees referred to when on a visit to Dolosbage a few years ago. The tree is allied to the toon ("red cedar"), and like the timber of that tree is too valuable for ceilings and other indoor work to be used for tea boxes. It is said not to stand exposure to weather, and yet, strange to say the outriggers of canoes are we may say invariably formed of the light timber of *lunumidella*. A diameter of over 3 feet in 17 years is certainly encouraging. While the trunks would supply valuable timber, the branches could be used as firewood, hardwood not being always available for fuel purposes.

GOLD AND GEMS.—Now that the time has come for the application of capital and enterprise to the development of our mining industries, it behoves the Government to do its share in a rather more practical way than the mere concoction of a restrictive and impracticable ordinance. The time has come for the Ceylon Government to indent on Australia for the use of a diamond drill with the services of a mining expert to search for gold, gem and also new plumbago deposits. It is quite likely that attention to the deep mining of our auriferous quartz as well as of gem deposits would be richly rewarded.

SARAWAK.—A very interesting report of a visit to Sarawak by Lieutenant Hamilton, the Acting-Governor of Labuan, and Consul-General in Borneo, has just been issued by the Foreign Office. Of late great progress has been made in the cultivation of pepper, and the total export for last year is estimated at about 1,000 tons. The pepper gardens are owned by Chinese. A large experimental tobacco plantation has been established by the Government with a view to ascertaining whether the plant will pay in Sarawak. Coal mines are being worked on the Sadong River. The daily output at present is 30 tons; the expense is small, and this quantity is sufficient for the requirements of the Government while the surplus meets with a ready sale at Singapore. The Rejang River, the largest in Sarawak, is navigable for vessels of a moderate size for upwards of 160 miles. The population along the river is steadily increasing. The revenue derived from the river trade last year exceeded the expenditure by \$13,000. Besides the local trade, which is carried on in small schooners, timber is shipped direct to Hongkong. One of the great staples of Sarawak trade is sago, the great depôt for which is Nurka, a coast town of about 8,000 inhabitants, all of whom are concerned in the preparation of sago. In 1888 over 11,000 tons, valued at \$124,260 were exported. The total revenue of Sarawak for 1888 was \$361,615 and the expenditure \$341,482, leaving a surplus of \$20,133.—*London Times*.

CINCHONA BARK IN 1889.—The annual report of Messrs. Lewis & Peat which will be found on page 646, contains some interesting facts; but we are rather surprised to see that while the imports for last year are in excess by 1,100 packages of those in 1888, in respect of deliveries there is a falling-off by a similar quantity. However, it is evident that the stocks of quinine have been considerably reduced, chiefly through the large demand for the United States of America where consumption is steadily on the increase, while the influenza epidemic in England has also drawn attention to the good qualities of quinine. In the past seven years we see that while 480,645 packages were imported, the deliveries amounted to 498,199. It is a striking fact that in no instance did the bark analysis of 1889 average higher in quinine than in previous years: in the case of Ceylon, there is a falling-off from 2½ to 2¼ per cent; Java continues at 4; India is described as very poor at 2 against 2½; while the highest Bolivian average is 4½. It is very striking to note in these tables how in eleven years, the price of bark (Yellow Calisaya) had fallen from 8s per lb. (in 1878) to eightpence (1889) while Sulphate of Quinine (Howard's) is now 1s 6d per ounce against 13s in 1878 and German 1s 3d against 12s. If quinine were only appreciated and utilised throughout Europe as it is in America and if the peoples of India and China came to use it, there would be a profitable market for all the bark that could possibly be raised in both Eastern and Western countries.

NEW INDUSTRIES AND BOUNTIES:

OUR FIBROUS PLANTS AND PULPOUS OR TEXTILE FABRICS:
A PAPER MILL—FIBRES—PEPPER GROWING.

A gentleman who has given much intelligent attention to the question of the utilization of the fibres to be obtained from plants grown in this island, suggests that perhaps it may not have been wise to have limited the scope for their employment to the manufacture of textile fabrics only. In his view there is a far wider field for the utilization of the very numerous fibre-producing plants already known to us in the manufacture of pulposus material. There is no doubt that there are many sorts of fibre which, while unsuited for working up as a textile, are admirably adapted for such matters as papermaking, &c. from pulp.

We have but very recently seen an instance of the kind referred to in the case of the straw-board which the Stanley-Wrightson Syndicate are using for the manufacture of tea-boxes. But that is but one case out of very many that might be cited to prove how great a pity it is that so much valuable vegetable growth should be allowed to remain unutilized. We have too often directed attention to the number and diversity of these to render it necessary that we should here make fresh reference to them. If the Stanley-Wrightson Syndicate carries out its proposals to their full extent and establishes Mills in Ceylon for the purpose of manufacturing straw-board for its own requirements, we feel sure a great impetus will be given to the further prosecution of industries of a similar character. The advance in science of but a very few years comparatively has completely changed the conditions on which the manufacture of solid goods from pulp used to be dependent. The enormous pressures which can be brought to bear through the agency of hydraulic machinery has rendered possible the treatment of many fibres which before the introduction of that machinery were necessarily regarded as so much waste material.

There will be many of our readers doubtless who have seen in operation in different parts of the world, processes which might be usefully added to the list of Ceylon Industries. Now that the Manufacture of Cotton Goods has been introduced among us, and that having, as we believe, a prosperous future before it,—a start has been made which might readily receive development, and the erection of a Paper Mill might next be tried. Of course we do not suggest the attempt to rival the high-class papers of Europe. We only make the suggestion that most of our local fibres are well adapted to the manufacture of those coarser papers, the use of which enters so largely into all modern trading concerns. If some of our readers can by their experience enlarge upon this subject, we feel sure they will be doing useful service to the Colony.

But while thus advocating the establishment of a new and, as we believe, promising manufacture, we would still urge the attention of planters and others to the advantage of utilising Aloes for their fibres and of promoting an export trade for Ceylon such as has become so important in the case of Mauritius and Bahamas, &c. Here is an interesting communication which has reached us by last mail from Mr. F. Cummins (formerly of our P. W. Department) who has taken so much interest in the subject:—

Penryn, January 23rd.

John Ferguson, Esq.

Dear Sir,—I forwarded to you a few days ago a parcel containing a sample each of Manila, Aloe and Sisal fibre. If the description given of the latter "a greyish green colour with thorny spines on the edges of the leaf" be correct,

you will find it growing in the N.-C. Province. I can recall having seen a lot of it growing on the roadside at a village named Ratmaligahawewa lying between Madawachchi and Horowa Potana.

I am told that the price of a Sisal fibre extracting machine is £20 and is sold by Mr. Van Buren, manager of the Industrial Machine Works, Jacksonville, Florida.

I hope to be able to send you a plant or two of a rare species of Aloes of a dark green colour bordered with a broad bright band of yellow and thorny spines on the edges of the leaf.—I am, sir, yours truly,

F. CUMMINS.

I think Mr. Davis's suggestion about Manila hemp worth consideration. It is considered the best of all fibre for rope making and realizes the highest price. The samples sent by Mr. Cummins, can be seen at our office. We would suggest that one or other of our Ceylon Machinery Firms take steps about getting a Sisal Fibre-extractor or such information as may enable them to judge of its usefulness. A bounty from the Ceylon Government for the first ton of marketable aloe or sisal fibre might have a good effect, and prove money well spent in starting a new industry,—an industry moreover which would be certain to benefit a large number of the natives. Bounties for the supply in quantity of new products is one of the simplest and most practical modes of helping to develop fresh and suitable industries, which can be adopted by the Ceylon Government. The total outlay is known from the first and it is ridiculously small as compared with the cost of an experimental field on official account, or the average of irrigation votes. In this way, why should not the Assistant Agent of Kegalla be empowered to offer moderate, but sufficient bounties, to the villagers who will bring him appreciable quantities of pepper and so endeavour to revive an industry which led the Dutch over two hundred years ago to declare that pepper, far more than coffee, was likely to be the richest and most abundant product from the interior of Ceylon. The Three Korales was then the great pepper-growing district of Ceylon; but the industry—a purely native one—has nearly, if not quite disappeared. Would its revival and prosperous extension—there is no tropical product for which at present there is a better market—not be as great a feather in the cap of Governor Sir Arthur Havelock as the creation of a new Province and the connected works, has been to any of his distinguished predecessors?

CEYLON TEA IN LONDON:

MEETING OF THE TEA COMMITTEE OF THE LONDON
ASSOCIATION.

(Copy) 4 Mining Lane, London, Jan. 31st.
A. Philip, Esq., Secretary,
Ceylon Planters' Association.

DEAR SIR,—Referring to your letter of November 2nd last I enclose copy of minutes of meeting of our Tea Committee held here on Monday last, 27th instant.

In regard to the scheme for advertising Pure Ceylon Tea I need only add that I shall be prepared to carry out here any arrangements that your Committee think it advisable to make.

I enclose copies of the circulars from the Indian Tea Districts Association in regard to the regulation of supplies of tea for sale in London.

I also enclose copies of the letters that have appeared in *The Times* as to the Tea Duty, and I may add that I have sent to that newspaper a copy of the resolutions of the Tea Committees on the subject. You will see that there appears in the correspondence a wide discrepancy in the figures given for the Home consumption of tea in the United Kingdom, on the one hand Sir R.

Lethbridge gives the figures for the Imports: on the other hand Mr. Roberts has given me as the authority for his figures the annual circular of Messrs. Stenning, Inskipp & Co. I do not know where that firm obtained their figures, but there is no doubt, I think, that they have fallen into error. The nearest approach to an estimate of the Home consumption that we can make is by taking the Customs returns of the weight of tea on which duty has been paid, and I have good authority for giving the following figures for the four past years as the weights in question:—

1886 ... 176,600,000	1888 ... 184,200,000
1887 ... 180,550,000	1889 ... 186,890,000

These figures show a steady increase in the three years of nearly 2 per cent per annum. The increase of population is nearly 1 per cent per annum. No account is taken here of the increased number of cups of tea consumed owing to the displacement of China by British grown tea.

For the figures I have the authority of Messrs Lloyd, Matheson & Co. supported by the figures given by Messrs. W. J. & H. Thompson,—I am, yours faithfully,
(Signed) WM. MARTIN LEAKE, Secretary.

Copy.—Minutes of meeting of Tea Committee held at 4, Mincing Lane, E.C., on Monday, 27th January 1890, at 3 p. m. Present:—Mr. T. Whittall in the Chair, Messrs. J. Anderson, Alex. Brooke, R. A. Cameron, T. Dickson, S. Gray, J. A. Roberts, H. K. Rutherford, C. J. Scott, J. L. Shand, A. G. Stanton, W. J. Thompson, Jr., G. White, and the Secretary. 1. The minutes of last meeting were read and confirmed. 2. Circulars from the Indian Tea Districts Association, dated 16th and 18th, December 1889 were read and discussed. It was resolved:—"That the committee having had under consideration the regulation of supplies of Ceylon tea to the London market will be glad at all times to co-operate with the Indian Tea Districts Association when they can do so effectually, but looking at the regularity of imports of tea from Ceylon throughout the year they do not see that any assistance could be rendered at present by making special arrangements in regard to Ceylon teas."

3.—Letters from the Ceylon Planters' Association dated 2nd Nov. 1889 and from Messrs. Willing & Co., dated 14th Dec. 1889, on the subject of advertising Pure Ceylon Tea in the United Kingdom on a large scale, were read. After a full discussion the following resolution was passed:—"That the Committee are of opinion that it would be advantageous to advertise in the United Kingdom as proposed, but that if an opening could be found for effectual advertisement in Russia, the United States, Canada or the Colonies the benefit to Ceylon tea growers would probably be greater. Any advertising to be effective must be done on a large scale."

4.—A letter was read from Sir Roper Lethbridge, M. P., K. C. I. E., dated 26th January, on the subject of the recent letters in *The Times* on the probable effects of the proposed reduction or Abolition of the Tea Duty. After a discussion in which considerable difference of opinion was made manifest, the following resolution was carried with four dissentients:—"That in the opinion of this meeting the reduction of the Tea Duty will be advantageous to the Tea Growers of Ceylon."

Copy.—INDIAN TEA DISTRICTS ASSOCIATION.

REGULATION OF SUPPLIES.—Report of the Special Committee, appointed by the General Committee of the Indian Tea Districts Association at their meeting held on the 19th November 1889, to work on details of a scheme for regulating the supplies of tea placed on the market, with a view to prevent the depreciation in values, not infrequently caused by hurrying forward more tea than the buyers are able to deal with. The Special Committee, having had the advantage of conferring with the representatives of nearly all the leading brokers, has arrived at the conclusion that, looking to the difficulty of formulating any arrangement of a hard and fast nature, and considering the many conflicting interests involved, the

object in view can be best attained by a general understanding among growers and importers and the brokers. The Special Committee find that the following are among the contributing causes of a depressed market:—

(1) The unnecessarily large number of separate breaks sent home by gardens, thereby harassing the trade.

(2) The offering of an enormous quantity of Tea for sale on a single day.

(3) The printing for sale of breaks of tea before the teas are actually ready for sale in the warehouse, and consequent frequency of withdrawals from sale at the last month. The Brokers being more fully in possession of the information necessary to enable them to exercise control over supplies, inform us that it has hitherto been their endeavour, as far as possible, to confer together to a certain extent with regard to printing, but that more might be done by Merchants themselves to support their efforts. The Brokers are accordingly recommended to endeavour, as far as possible, to dissuade their principals from (1) Printing their teas for sale before all the teas of each break are actually in the warehouse, and have been bulked and worked. (2) Bringing out fresh catalogues of tea to be sold on the last days of the same week in which the catalogues are issued, when the total amount already advertised for sale appears sufficient, or more than sufficient, for the requirements of the trade.

Members of the Association are invited to do their utmost to strengthen the hands of their respective Brokers, and at the same time to endeavour to attend the fortnightly meetings of the Association, on Tuesday, at 2 p.m., to confer with one another, and with the Brokers, with a view to better regulation of the supplies put on the market.

ROBERT LYELL, GEO. SETON, R. G. SHAW, Members of the Special Committee.

ERNEST TYE, Secretary.

London, Dec. 16th, 1889.

INDIAN TEA DISTRICTS ASSOCIATION.

REGULATION OF SUPPLIES.—A meeting of the General Committee of the Indian Tea Districts Association was held on the 17th inst. to receive the Report of the Special Committee appointed to consider the question of Regulating the Supplies of Tea placed on the market.

The following members attended:—Chair—Messrs. Wm. Roberts (Jorehaut, Darjeeling & Tiphook & Co.); R. G. Shaw (Assam Frontier Co.); Robert Lyell (Geo. Williamson & Co.); R. B. Doake (Duncan Macneill & Co.); A. Bryans (P. R. Buchanan & Co.); J. Berry White (Jokai Tea Co.); W. L. Watson (Jas. Finlay & Co.); W. N. Clark (Begg, Dunlop & Co.); Geo. Seton (Octavius Steel & Co.); Henry Earnshaw (Alex. Lawrie & Co.); W. F. Raban (Gotoonga Estate); Arthur Thompson (W. J. & H. Thompson and Noakachare Tea Co.); George White & Co.; Gow, Wilson & Stanton; Arthur Capel & Co.; and Stenning, Inskipp & Co.

After a very lengthy discussion the following resolution was moved by Mr. W. L. WATSON, seconded by Mr. J. BERRY WHITE, and carried unanimously:—"That the brokers be requested to meet once a week, and endeavour by mutual agreement to regulate the offerings as far as possible in accordance with the demand at the time, and the members of the Association present hereby pledge themselves to support them."

It is hoped that all members of the Association and others interested will give their cordial support.

ERNEST TYE, Secretary.

14, St. Mary Axe, London, Dec. 18th, 1889.

VITICULTURE.—A matter of great importance to viticulturists has been worked out by a French botanist, M. Petit. He shows that the disease called chlorosis (characterised by the pale sickly yellow colour of the leaves and the stunting of the branches) is due to an excess of moisture in the soil—in other words, to defective drainage. Chlorosis is very destructive in French vineyards. M. Petit says that the moisture fills the cavities of the roots—which ought to be full of air—and practically chokes the roots.—*Australasian*.

CINCHONA BARK: ANNUAL REPORT ON LONDON MARKET.

(From Lewis and Peat's Annual Report on the Market for Quinine Bark.)

London, 21st January.

Our supplies of Bark for Quinine-making continue to show some reduction, having been packages of:—

	1889 packages	1888 packages
Ceylon, India and Java	54,545 against	61,460
South America, Bolivian Calisaya	9,552 against	7,810
Columbian Cuprea	455 against	1,230

	1889	1888
Total imported packages and Deliveries	64,552 against	70,500
	65,859 against	69,386

Shipments from Ceylon steadily decrease, as shown in our review (at the close of the season) 12th Sept. last.

Season 1888-89 1887-88

Being 10,800,030 against 11,705,000 lb
But India the Wynaad and Neilgherries increased, for special reasons last season to 3,000,000 against 1,700,000 lb and Java, mostly to Holland 4,700,000 against 4,000,000 lb

Bolivia shows some increase of fine cultivated Calisaya and total is given above.

Central America has sent scarcely any. A few old lots of old Cuprea have come to remind us that current rates are prohibitive for export from those regions.

The quality as a whole has not improved; we estimate the average percentage of Quinine in the

	1889 per cent	1888 per cent
Ceylon was about ...	2½ against	2½
Java ...	4 against	4
India, very poor ...	2 against	2½
Bolivian ...	4½ against	4½

The Darjeeling Bark, about 290,000 lb was manufactured in India, but with very disastrous results as compared with the price Quinine was procurable at in Europe.

Odd small lots came from Africa (St. Thomas) and West Indies. We hear a few trees were planted in Central Africa.

The feature of the past year was the unprecedented low price at which both Bark and Quinine were sold, the average being the lowest on record, viz., down to 1d to 1½ per unit for Bark and 11d to 11½ for Sulphate. The trade were fairly active throughout the year being aided by large speculative transactions, but the consumption has been very large, and America took from Europe a much larger quantity of Sulphate, no doubt because of her increase of consumption and great reduction in her own manufacture of Quinine.

Quinine; European exports to America estimated at 2,500,000 oz. in 1889 against 1,600,000 oz. in 1888.

The recent and universal epidemic of "Influenza" has greatly stimulated the present consumption and somewhat reduced the stocks of dealers and druggists everywhere. Some considerable deliveries have also recently been made to America.

The available stocks of Quinine are, however, too large—too much is manufactured for these times of "peace" and importers have so regularly supplied the auctions with Cinchona each fortnight, that there has been little chance of a permanent or serious advance in values.

Manufacturing competition appears keener than ever and it looks as if several of the large factories, who have always been eager to make "forward" sales of Quinine, have not worked profitably during the year, although they have turned out a large quantity.

There are, however, now, many large and influential holders of Sulphate of Quinine interested in maintaining prices, current rates are very moderate and our supplies do not seem likely to increase; confident predictions are current of further great reductions in the supply of Cinchona from Ceylon.

It is well to bear in mind that during the past seven years we imported 490,645 packages and delivered 498,140. To this has to be added the very large and increasing quantity of Java brought to auction, and all sold and delivered, each month in Holland, shewing that though the supply has been great, the actual consumption of Cinchona has been greater. Quantity offered in Holland: In 1889: 21,750 packages 4,500,000 lb; in 1888 18,220 packages 3,100,000 lb; in 1887 1,200,000 lb.

Quinine per ounce, in bulk.

TEA GROWING IN THE CAUCASUS.

It is part of the policy of the Russian authorities to encourage, whenever practicable or possible, the production, within the limits of their own territory, of all commodities in general demand throughout the Empire. In accordance with this principle the Government has lately been doing what it can to foster the cultivation of the tea plant in a portion of the Muscovite dominion which is stated by experts to be specially suited to the growth of the shrub, namely the region lying in the district of the Western Caucasus, between Batoum, on the Black Sea littoral, and Sukkum Kaleh. The idea of attempting the culture of the tea plant in this part of the Caucasian province is by no means new, and private enterprise has, for some years been quietly at work in the hope of developing something like a local industry of fair extent. Fully a century ago tea plants were grown in the open air in the public gardens of Sukkum Kaleh. They stood the winter well, and, though no endeavours were made to convert the spring and summer produced leaves into actual tea for brewing, yet the appearance of the shrubs was, in the opinion of all who had seen them, extremely favourable. In fact, the efforts to acclimatise the plant proved a success, though the innovation as is often the case in other branches of commercial enterprise, led to no practical results. It was not persevered in because of the slowness of its development. There were no chances of immediate or early profit, so the enterprise was abandoned, in spite of the proved adaptability of the western half of the Caucasus for the growth of the tea shrub. That the plants cultivated years ago were suited to the locality was demonstrated at the recent Tiflis Exhibition. Prince Bristow showed a tea plant 40 years old of magnificent growth in the gardens of the Exhibition, where it attracted general attention, and was considered quite one of the attractions of the show.

But, moved by the fact that Russia imports annually over 50,000,000 roubles—over £5,000,000—worth of tea from China, several enterprising Russians have been making practical attempts at tea cultivation and the manufacture of tea in the Caucasus during the past five or six years, and so far, it would appear, with not little prospect of success. The plants not alone thrive and yield an abundance of leaves for "flushing," as it is termed but they seed abundantly. M. Solovtsov, a Russian agriculturist, who is greatly interested in the promotion of the tea industry, recently showed some five year-old plants grown in a plantation in the open air, which left nothing to be desired; and these, moreover, seeded so abundantly last season that he has gathered sufficient of them to sow next year half a dessiatine, an acre of land. But the most important undertakings in the direction of the cultivation have been made by the Brothers Barkaley, who planted already six or seven years

* New terms for 1882 to 1888, equal to about 11 per cent more than old terms.

The influenza already referred to has stimulated trade this month, and very large sales of Quinine have been made from manufacturers and second hands to exporters, the trade, and to speculators at from 1s 2½d up to 1s 4d for German forward delivery, and 1s 2½d to 1s 3½d spot. The first auctions last Tuesday went briskly at 5s to 10 per cent advance, say 1½d to 1½d per unit, and 3,931 packages were offered and 2,191 sold, and at the sale of Java in Holland on the 16th instant, 3,200 packages were sold.—Your obedient servants,

LEWIS & PEAT, Brokers.

ago a large stretch of ground near Sukkum Kaleh, devoted only to the shrub. Their efforts were so successful that they extended their gardens considerably three or four years ago, and further experimental plantations were made on their estates at Dushat, at Senaks and at Sogdidy, all situated in the same region of the Western Caucasus. The attempts, however, to manufacture a marketable tea from the leaves grown, on the Caucasian plants were not at first so successful as the projectors hoped. When brewed the beverage they yielded was found harsh, bitter, and strongly astringent. In a word, the tea was unfit for the pot, and, therefore, useless for sale. But this fault was only one of manipulation. So the owners of the tea-gardens sent a couple of their representatives to China to study thoroughly the methods of preparation in the cradle of the industry, and obtained further the services of a Chinaman thoroughly up to the business. The result has been extremely gratifying to the Messrs. Barkaley. There has been a marked improvement in the quality of the Caucasian product, and all the statements made about its being naturally and inevitably bitter and poisonous have been shown to be unfounded, the objectionable qualities that formerly distinguished the tea of the Caucasus gardens being clearly proved to have resulted from a bad process of manufacture. In the judgment of tasters the teas are by no means perfect—nor were those of the Assam gardens at the beginning of the Indian manufacture. But the plants grown and the tea manufactured in the Caucasus, of which samples were shown in the recent Tifis Exhibition, have led French and German experts to speak with the greatest hopefulness of the future possibilities of the Caucasian tea industry, and the Russian Government is doing what it can to foster and encourage the enterprise of the tea cultivators in this part of the Empire.

The success of tea growing in the Caucasus will depend upon a good many considerations. The climatic conditions are no doubt suited to the culture of the *thea sinensis*, or the analogous plant of Indian origin. The shrub is by no means a delicate one; it stands exposure fairly well under proper systems of tending and management, and takes no harm from the rigours of even a cold winter. The seasons in the Caucasus are very much like those of China, the winters not more severe, and the summers about as hot. In fact, French and German naturalists, who have made a study of the subject, assert that there is no country in the world better adapted for the growth and production of tea than the littoral of the Black Sea just between Batoum and Sukum Kaleh, where they assert tea gardens should thrive in the generous climate which is at once warm, moist, and equable. It may fairly be assumed that the climatic conditions of that portion of the Caucasus province referred to—as well as some others—are at least as favourable to tea culture as Assam and Dajilling, where the industry has attained such enormous development in the last quarter of a century, to say nothing of less promising regions, where the cultivation of the tea-shrub is yielding satisfactory results now, though such an idea would have been derided a few years back. But a great deal, too, depends upon kinds of plants selected for growing. For what will thrive and do well in one country is by no means certain to answer in another, even when climatic conditions appear to be precisely the same in both. To give a standing instance. The tea plant of Northern India, the plant from which the Assam and Darjilling growers obtain the supplies they send all over the world, is not the familiar tea plant of China, nor is it even like the plant which the Chinese have for thousands of years cultivated. It is true that the first experiments in Indian culture were made with plants imported from China, and with seed obtained from the same source. But there is very little doubt that if Indian cultivators had stuck to the China tea shrub, their attempts would have had very different results, and the grower of Assam and Darjilling would have produced nothing but a somewhat coarser and harsher species of Chinese leaf, which would never have taken, as Indian teas has, to the extent of threatening the supremacy of the Chinese article. It was the discovery of the wild tea of the Himalayas, the

native or indigenous shrub of India that, to use the current phrase, "made" the Assam tea industry. It is a plant far more robust than that of China, far larger, yielding a greater quantity of leaves at each picking, and otherwise better adapted to the soil and climate of the southern Himalayan regions in which it is so extensively grown now. If the Caucasian cultivators can only hit upon the right variety suited to their uplands and valleys, they may succeed ere long in turning out marketable tea in quantities likely to affect the imports from China. But this is probably a contingency very far afield as yet.

It is strange to note over how wide an area the culture of the tea plant is gradually extending, and how numerous are the sources of supply which are gradually opened to it now. Not many months ago we dealt in our leading columns with the success of the attempts at tea growing made in a colony of our own, Natal. Here, too, a variety of the Indian tea had been selected for planting, and the results were so satisfactory that tea-culture may be regarded as one of the future industries of South Africa. Some half-a-dozen companies are already engaged in it, and more companies are already engaged in it, and more will follow as the local product increases in repute. The Malay Peninsula promises also to become one of the tea countries of the world, the prices obtained for Johore tea rivaling those paid for the finest Indian and China products, and Johore has this great advantage over all other tea lands, its peculiar climate will allow of the leaves being picked—"flushing" as it is called—all the year round. In other parts where the shrub is grown this can only be done at certain seasons and at intervals apart. Malacca is also going in for "tea. But the latest undertaking of the kind is confined to New Zealand, which has determined to enter into the general competition in tea growing. The climate and soil of both the north and the south island are stated to be favourable to tea culture, and last October a large consignment of tea seed was imported from Ceylon for the purpose of starting the necessary plantations. What with all this, to say nothing of the attempts in the Caucasus, it is pretty evident that the world's supply of the fragrant "leaf" we owe originally to the Chinese stands little chance of falling off.—*Morning Post*.

KOLA NUTS AND PRODUCTS.

We are indebted to an Uva planter for copy of a letter and circular from a Glasgow Homœopathic Chemist who makes a speciality of Kola nut preparations. We quote as follows:—

Oct. 29th.—The nuts sell at from 6d to 1s per lb. in London at present (of course Mr. P.'s preparation is admixed, flavoured, &c. so as to render the paste, chocolate &c. palatable). The Gold Coast is at present the chief source of supply, though any hot climate, he doubts not, would suffice. He had one of the plants exposed in his window for some weeks but it drooped and died from insufficient warmth. As well as being used as an article of diet in the forms he (J. C. P.) prepares, it has doubtless a great value before it as a source of *Caffeine* of which it contains a fairly high percentage, so that he should fancy its cultivation might be profitably carried on; he sends pamphlet with analyses, medical opinions &c. He will be glad to try and procure a small supply of the fresh nuts—as commercially met with they are baked and sterilized.

From the circular:—

POTTAGE'S KOLA NUT PASTE, JUJUBES, ELIXIR, AND CHOCOLATE.

An invigorating and sustaining beverage for Invalids, Delicate Children, and Dyspeptics, and to those in health a positive luxury.

This delicious preparation is manufactured from the finest Kola Nuts (specially imported), and is made by a new process which preserves entire all the valuable quantities of the nut in a form at once agreeable to the taste, and easily digested by the most delicate stomach.

The best medical authorities accord to it the highest position in Dietetics. It is recognised as a most important and valuable discovery, and likely to be as largely consumed as Tea, Coffee, Cocoa, or other fashionable beverages of the day.

It may be taken to Breakfast, Luncheon, or Supper.
POTTAGE'S KOLA-PASTE AND KOLA-CHOCOLATE.

The marvellous abstaining powers credited to the fresh and dry nut by the natives on the West Coast of Africa and in the West Indies induced us to have it chemically and physiologically examined, with a view to placing it before the public in a pleasant and convenient form.

Kola contains a large percentage of caffeine in combination with other valuable ingredients, to which are due its sustaining and invigorating properties.

The Medical Journals state that the beneficial effects of Kola upon weak stomachs, sluggish livers, and kidneys, added to its invigorating action upon the whole system, have been fully ascertained at the Hospitals and Convalescent Homes, also by the Medical Profession, who now invariably prescribe it. Kola-Paste does not, like Cocoa, bring on biliousness or derange the digestion; the weakest stomach benefits from its use. Kola-Paste keeps the system in a healthy and normal condition, imparting tone and vigour to all the organs upon whose perfect performance the proper well-being of the body so much depends. It restores impaired organs to a normal condition, and enables a thorough assimilation of the food to take place. It is so pleasant in flavour that the daintiest palate takes it with delight.

A careful analysis shows that the yield of Caffeine from the Kola nut is greater than in commercial teas and coffees. In comparing the Kola nut with coffee, tea, and cocoa with regard to their nitrogenous principles, chemically defined any crystallizable, it will be found that the Kola takes the first place. The physiological effects of Kola nut and pure Caffeine are identical. Kola nut is an undoubted stimulant in wasting diseases, and by its bitterness and astringency acts as a powerful tonic in cases of deep-seated lesions of the digestive-organs.

Its place in therapeutics is far above that of Maté (Paraguay tea), Coca and Paulinia Guarana).

Kola Chocolate for Expeditions. Kola-paste and Kola-Chocolate in Chronic and periodical Headaches.

Kola-paste and kola-chocolate for delicate children, invalids, students, and examiners; Kola-paste in derangement of the nervous system; in complaints affecting the heart; Kola-paste and kola-chocolate for travellers, city men, students, &c.; Pottage's elixir of kola; Kola jujubes.

DIRECTIONS FOR USE.

Kola-paste:—Mix one tea-spoonful with as much hot water as will form a thin paste, then add boiling water or, preferentially, hot milk to fill a cup. Cream and sugar may be added, if desired, to please the taste.

Kola-chocolate is convenient for city men or travellers who cannot readily obtain hot water. It is put up in boxes containing eight tablets, a doze being from one quarter to one-half a tablet, taken when required.

Kola elixir is taken, a tea-spoonful at a time, in a wine-glass of water.

PRICES.

Kola-paste,	... 1s, 2s, and 3s 6d per bottle.
Kola-chocolate,	... 1s per box.
Kola-elixir,	... 1s, 1s 9d, and 3s per bottle.
Kola-jujubes,	... In boxes, 1s, 2s, and 3s 6d.
	By post, 3d extra.

PLANTING IN DELI—TOBACCO, &c.

On the 6th February another section of the Deli railway line towards Serdang so far met requirements as to admit of its formal opening that day amid festive display and public rejoicing. Now that communication by rail with Serdang and Bo-bongan takes rank among accomplished facts, hopes run high that these districts will soon recover lost ground. Of late, tobacco growing there has struggled with adverse fate, but the iron road is expected to mend matters, and to ensure the planters coming

triumphantly out of their difficulties. The railway company set a good example by venturing where ordinary capitalists feared to tread. The Deli *Courant* of the 8th Feb. hopes great things from the venture.

The tobacco crop last year in Serdang, so experts say, has proved so unsatisfactory and below the mark that it is feared many planters will have to close business. The leaf proves in many cases poor stuff. In Bedagei, the outlook is no better. Two estates which did well for a while have had to close notwithstanding. Objection to the leaf lies in its too dark colour and inability to stand test in burning. The same disadvantages, so brokers in Holland say, tell against plantation enterprise in Padang. Assahan has forged ahead, and promises well for the future. Its leaf calls attention by its light brown colour, fineness, and large size. Batu Bara and Pagurawan give scant promise for the future. Success looks so distant to planters in Siak and Palembang that many of them in the former district have given it up.

West and North West of the tobacco plantations in Deli, independent tribes of a cannibal race styled Battaks people the mountain region. They are rank heathens, and likely to prove a standing danger to the planters should the Achinese gain them over, as they are now trying to do. Should the Achinese convert them to the Mahomedan faith, the consequences may prove detrimental to both the planters and the Government. To defeat Achinese intrigue, a gentleman named Cramer has been raising subscriptions in Holland for a Protestant mission among the Battaks under the guidance of a worker named Kruyt. The preparations for the mission are already pretty well forward.

Bad sorting and shortcomings in packing begin to tell heavily against Deli tobacco in the market. Formerly, sorting so hit the mark that buyers could rely on samples, but, nowadays, matters have changed for the worse. Bales too often come to market assorted at haphazard, with leaves good, bad, and indifferent packed together. Buyers no longer trust to samples, and Deli tobacco begins to get a bad name owing to so few planters caring to keep up its high reputation of old by setting quantity before quality. No wonder the *Courant* urges planters to do their utmost to recover lost ground and make head against growing competition.—*Straits Times*.

A NEW PISCICULTURAL EXPERIMENT.—In stating the other day that Mr. Le Mesurier had brought over trout *ova* from India (we local "Times") were mistaken. It appears that the trout experiments in India have failed. Mr. Le Mesurier brought over a lot of "Laber" and "Gourami" fry for the purpose of introducing them into the low-country for food purposes. As to how enormously reproductive the first is Mr. Thomas is a witness and "Gourami" is a well-known Mauritius fish introduced into Madras of late years. These fry have been put down in Kandy, and will by-and-bye be distributed to various parts of the country.

WIRE SHOOT ON HATHERLEIGH ESTATE.—Mr. John Brown of the Colombo Commercial Company and Uva Company, has been on a few days' visit to Hatherleigh Estate, and will leave for Ratnapura this afternoon. The wire shoot from the top of the hill to near the former dam just above the store has been fixed, and green leaf bags of about 50 lb each was sent down yesterday for the first time. The leaf is carried up from Rawrath Estate in Middle Kukul Korale through Aigburth and Aberfoyle Estates in Kolonna Korale, and then over the ridge on to the extreme top of Hatherleigh Estate which is in Atakalan Korale. The coolies are thus saved the heavy trudge up and down Hatherleigh hill. The wire is about 3,000 feet long, and so steep that the bags come down in about 28 seconds.

NOTES ON PRODUCE AND FINANCE.

In some of the brokers' circulars of last week reference was made to the sale of Perak tea in Mining Lane. The first consignment consisted of an invoice of seventy-eight half-chests. It found ready buyers; Broken Pekoe at 1s 0 $\frac{1}{2}$ d., Pekoe at 11 $\frac{1}{2}$ d., Pekoe Souchong at 9 $\frac{1}{2}$ d., Souchong (a single package) at the same price, and Dust at 6 $\frac{1}{2}$ d. per lb.

It was suggested by tea importers that in weighing the tea at the Customs the old practice of disregarding the odd ounces shown in the gross weight of a package should be given up, and instead, half pounds should be reckoned. The dealers strongly object to this. At a meeting of the committee of the Teadealers' Association held last Friday the question was further discussed, and an opinion against any change in the direction indicated was expressed. The dealers contend that the present system has been in vogue many years, is thoroughly understood, and if it were satisfactory to importers when tea was double the price it is now, they argue this is not the time to make a retrograde change, more particularly as the packages are made to a more even tare than formerly—so much so that the small overweight and the draft do not cover the inevitable loss involved in distributing tea in small parcels of ounces and pounds.

Should the experiment now about to be made of planting olive trees on the lower hills in the Rawul Pindi district prove successful, another and very valuable source of employment and income will be added to those which have already benefited India.—*H. & C. Mail*, Jan. 31st.

MINERALS IN SIAM.

A correspondent's contribution, which we give in another portion of this impression, will afford some interesting information on a subject which has hitherto been only, as he expresses it, gathered piecemeal by travellers throughout Siam. That the country has been vaguely understood in a general manner to be rich in the more precious minerals and in stones has been more or less known. Those who have only visited Bangkok hear reports, and have evidence furnished them of a rude and unskilful search for gold and rubies, showing that there are considerable stores in various parts of the country. We are told now that many would-be concessionaires are endeavouring to obtain concessions for exploiting these stores, and working them on a proper scientific basis. So far the efforts of those who have received concessions have been in the main for gold. The English company formed some two years ago was for the purpose of working the precious metal, and the reports that have been received since have been of a favourable nature. Their concession lies on what is known locally as the west coast, though it is in reality the eastern side of the Malay Peninsula. The new concession which our correspondent now tells us has been granted to a Singapore firm is to the eastward of the capital, at a place which has already attained some notoriety as a gold producing centre, as well as by the tragic fate which overtook Phra Preecha, the former manager in charge of the mines, who was executed for reasons which formed the basis of some diplomatic representations at the time. It has been abundantly demonstrated that gold in very paying quantities can be obtained here; and, with the aid of new machinery, which the concessionaires will doubtless place on the ground, there is every reason to believe that it will yield good reward. Gold always proves magnetic in its influence to attract all classes, and if it generally becomes known that there are many spots where it can be profitably mined in Siam, the Government will have to use some circumspection in the way that they make grants. There is no reason why, with due foresight, they should not profit largely by the natural resources of the country, without having the number of rowdies who so frequently collect when a "rush" takes place in any country.

But it is not only gold that will prove remunerative. It has been surmised by all who know the lower part of the Malay Peninsula that the stanniferous properties which have done so much for the

Protected Malay States on the western side of the Peninsula, and which promise equally for Pahang on the eastern side, would be continued through the States which Siam claims in the northern part of the Peninsula. The Island of Junk Ceylon, on the West coast, has long been noted for its tin production, and our correspondent points out that nearly all upcountry streams of these States have been scratched in a perfunctory manner by Chinese. It is evident they have not got to the bottom of deposits, as they have no means of keeping a mine dry when the water begins to collect at all. Still there are some productive mines, and the possibilities foreshadowed under a more scientific principle are considerable.

The whole subject of minerals in Siam is one which the Government may well pay some attention to and approach in a cautious, though not jealous, spirit. If concessions are granted on reasonable terms, and only to substantial persons who are known to be of some standing, there should be a very good income derived from royalties. The Europeans to whom concessions are granted would be able to introduce experts and proper machinery to fully develop the riches that might be in their particular ground. But the Government will have some responsibilities for the receipt of their royalties. The present means of communicating in many of the mining districts are exceedingly defective, and it may well be expected that some funds which would accrue to them should be expended in providing better roads and in other wise making the neighbourhood of the mines more easy of access. The Government, we repeat, can do much by judicious means in thus generally developing the country. Hitherto a jealous eye has been cast on such ideas, where only produce and necessary caution would have been sufficient.—*L. & C. Express*, Jan. 31st.

[In the communication referred to, gold, tin, and precious stones, especially rubies, are described as plentiful. Iron and coal are also mentioned, but we are disappointed that nothing is said about the lignite which, some time ago, we were led to hope could be landed at R5 per ton in Ceylon.—*Ed. T. A.*]

PLANTING AND TRADE IN CEYLON.

THE ANNUAL REPORT OF THE COLOMBO COMMERCIAL COMPANY.

With this you will receive an early copy of the report to be presented to the shareholders of the Colombo Commercial Company on Wednesday next. The particular character of the business carried on by that Company, its dual nature, which includes transactions of a more private kind than have to be referred to in the Reports of companies restricted to planting operations only, necessarily renders the reading of its Report of less general interest than most others I have to send you. Nevertheless it may perhaps be said that the very fact of that dual nature renders progress made by the Colombo Commercial company more strictly a gauge of the general prosperity of your local trade than does that of merely planting companies. In this sense, therefore, although no great success is as yet claimed for the operations the Report deals with, the Ceylon public may feel gratification at the statements made; for not only are the holders of preference shares to be paid in full their claim of 6 per cent, but those of the ordinary shares will also receive a small dividend. This, of 2 per cent only, is certainly not a very grand one, but it will be something to those who have often hitherto of late years had to go without any at all.

The figures given in the accounts are classed so generally that it is impossible to say whether the net profit made of £2,538 odd during the year has been due to the planting or to the commercial

operations of the Company. It may be, indeed, that they have accrued solely upon the latter; for the brief remark in the report that "the planting operations of the Company were disappointing during the past year owing to the low price ruling for tea during the first six months of 1889" would tend to support a supposition that no profit whatever was made upon them. Assuming, however, such a supposition to be warranted, it must be borne in mind that on most, if not on all of the properties in which the Company has an interest, the process of change from the cultivation of coffee to that of tea has been going on year after year for a long time past, causing an outlay which should be met—as it has been—solely out of profits made in other directions.

It is disappointing to read, as we do in this Report, that "in spite of all endeavours to retain the area of coffee on the Company's estates, it is gradually diminishing, and has now become insignificant." It is quite certain that, in view of the high prices which coffee has of late been fetching, every endeavour possible would have been made to keep the coffee alive; and we think that we must conclude with regret that, save in some exceptionally favourable localities, Ceylon has seen the last of successful coffee cultivation. The report tells us the story generally heard with respect to cinchona. The price obtained for it has only just sufficed to meet the charges for harvesting, shipping, and landing here, and this article has therefore contributed no quota towards the profit made.

COLOMBO COMMERCIAL COMPANY, LTD.

REPORT.

To be presented to the Fifteenth Ordinary General Meeting of the Company, on Wednesday, the 12th day of February 1890, at 12-30 o'clock p.m.

The Directors are now able to place the following Annual Accounts before Shareholders, viz:—Profit and Loss Account for the year ending 30th September, 1889. Balance Sheet made up to 30th September 1889. From these it will be seen that the year's operation have resulted in a profit of £2,538 7s 10d, which with the balance of £79 8s 11d, brought forward from last year, gives a total of £2,617 8s 9d at the credit for profit and loss. The Directors propose that the sum of £1,089 be now devoted to the payment in full of the Dividend on the 6 per cent Preference Shares for the year ending 30th September last, and that a Dividend of 2 per cent on the Ordinary Shares for the same period be also paid; this latter will absorb a further sum of £1,400, leaving a balance of £128 8s 9d to be carried forward to next account. The general trading business of the Company continues to show a satisfactory increase, and the Directors hope for further expansion in this respect, as the Tea planted throughout the Island comes into bearing. The planting operations of the Company were disappointing during the past year owing to the low price ruling for Tea during the first six months of 1889. The market price for Ceylon Tea has since considerably improved, and the prices now ruling are satisfactory. Should they continue the Directors look for a better result from the working of the Company's Estates for the current year, as the yield of Tea should exceed last season's on account of the bushes being nearer maturity. In spite of all endeavours to retain the area under coffee on the Company's estates it is gradually diminishing, and has now become insignificant, but tea is being planted up as the coffee decays.

The Company brought to market a considerable quantity of cinchona bark; the prices obtained for this article, however, did not much more than cover the cost of harvesting, shipping and landing in this country.

Mr. John Brown, Chairman of the Board, left for Ceylon in November, and will inspect the properties in which the Company is interested.

THE UPAS.

The devil, some say, is not so black as he is painted: neither is the Upas the embodiment of all that is malignant in the vegetable kingdom as it has been popularly believed to be. This tree has long been regarded as exercising deadly effects on the unwary traveller who is foolish or ignorant enough to rest beneath its treacherous branches: and to court sleep within the precincts of its shade has been considered tantamount to laying oneself down to die. It has thus become a familiar subject for allegory, so much so that the very name conveys sinister associations. A paper in Dr. Watt's *Dictionary of the Economic Products of India* (the first two volumes of which have recently been issued) gives an account of this interesting botanical specimen, however, which dispels much of the superstition and evil reputation that has hitherto enveloped it, while an explanation is given of the circumstances under which its notoriously bad character came to be acquired.

A Dutch surgeon by name of Foersch, who flourishes apparently in Java about the end of last century, put in circulation preposterously exaggerated statements about the plant, and appears to have been either the author or the victim of a pretty considerable hoax. The tree was described by him as growing in a desert tract with no other vegetation within a range of ten or twelve miles. It was customary to offer condemned criminals a free pardon if they went and collected some of the poison, but out of every twenty who made the attempt not more than two ever returned. (Most probably the majority thought it prudent to evade in some other direction.) Foersch states that he conversed with some of those who had survived the ordeal, from whom he learned that the ground was strewn with the bones of those who had perished in their endeavour to work out their salvation; and that such was the virulence of the poison that "there was no fish in the waters, nor had any rat, mouse or any other vermin been found there; also, that when birds flew so near the tree that the effluvia reached them, they fell victims." Many more equally absurd things were written at the time and so passed into current belief.

There are two species of the Upas, the *antiaris innoxia* occurring in Burma and the Indian Archipelago; and the *antiaris toxicaria* indigenous to the Western Ghâts and Ceylon (although some authors have classified them as one). The foundation on which the ill-repute of the tree has been fabricated appears to be that certain of the localities in which it is found in Java are in themselves noxious owing to the nature of the ground, which is creviced with fissures communicating with the craters of volcanoes, and from these issue carbonic acid and sulphurous fumes in sufficient abundance to be fatal to animals who approached too closely. Similarly the waters of the adjacent rivers and lakes become so highly charged with sulphuric acid that no fish can live in them. In different places, however, the Upas rears itself side by side with other trees, and birds and lizards have been observed amongst its branches: so it cannot be so very pestilent a shrub. Moreover, it is cultivated in botanic gardens and seems to give no evidence there of the baneful influences that have been ascribed to it.

For all that, and although it has been much belied, the Upas tree is not altogether harmless. From incisions made in the trunk there exudes a white kind of gum-resin, which, mixed with other substances, probably merely to give it consistence, forms the *Upas antiar* or arrow-head-poison of the natives of Java,—this *antiar* owing its virulence to a crystalline principle, *antiarin*. The tree exhales

an *ariform* matter sometimes severely affecting those who climb it, causing in some cases eruptions and swellings, while in others it does no harm. The inner bark of the young trees, which is utilised to make into wearing apparel, if not properly prepared clings to the skin and excites distressing itching. In Western India the *Upas* is well known as the sackin tree, the tough, inner-felted bark being removed entire, forms natural sacks which are much used for storing rice. Ready-made suits are also provided in the same easy way, small branches forming the arms of coats and the legs of trousers, while the larger ones come in handy for the bodies of these garments. All that is required is to stitch the pieces together, and if really fine raiment of the kind is wanted the material is first rolled, dyed and tanned. Samples of these novel costumes were exhibited at the Calcutta Exhibition and attracted considerable notice. In Ceylon ropes are made of the bark, and there is a likelihood that it may also be found adaptable for papermaking. The seeds have been found to be free from *antiarin*, and contain an element which has been used as a febrifuge and in dysentery. This is how science treats most of our cherished fables.—*Pioneer*.

THE TEA TRADE.

Tea-growing districts have so multiplied of late that the entry of a fresh competitor into the overcrowded market will not be good news for the sellers however satisfactory the rivalry may be for the buyers, of what can no longer be termed with accuracy the "Chinese herb." The latest tea-producer is Perak, one of the small protected Native States of the Straits Settlements. Hitherto this territory has been best known as the scene of a great deal of mining speculation, which as some investors in this country have learned to their cost, is not quite the same thing as mining success. But the warm soil also yields tapioca, rice, sugar, coffee, and tea, though until recently the latter could scarcely be regarded as more than a promising experiment. It has now advanced beyond this probationary state, the first consignment to the English market having just arrived, and being, it is said, all that could be desired. The leaf must have been grown and manipulated with skill, since even the experts of Mincing-lane are inclined to speak favourably of it. Still better, the prices which the seventy-eight chests brought at public auction stamp it as quite up to the average mark, for it realised from one shilling and three-farthings for broken Pekoe, and nine-pence farthing for Sonchong, down to dust at sixpence three-farthings per pound. It is certain that further consignments will follow, and that the already congested trade will find more and more difficulty in obtaining a profit out of "cutting" prices. A bare profit is, indeed, about all that Mincing Lane looks for nowadays. The fortunes which were once upon a time the rule are extremely rare, and though a few large houses may still earn handsome incomes out of their immense turnover, the average is quite the other way. There was a time, not too distant for middle-aged men to remember, when to get a clever lad into one of the great tea houses was to insure his future. In a few years he had mastered his trade, so far as any mortal can ever be said to master the intricacies of a business so changeable that the experience of one year is no guide to the operations of the next season's campaign. If the youngster was blessed with a delicate palate, he might then look forward with confidence to the day when rival houses would contend for his services as a "taster," his task being to sample endless parcels of leaf, and decide, by the aid of his tongue, their relative qualities and values. Such a gift was worth to the possessor of it considerably more than the salary of an Under-Secretary of State. Or the young teamen had often the choice of going out to "the country" for a period, "the country" being in those days, of course, China. Here in the opulent times of the trade, he lived in the Hong like the retainers of a Prince, and, if he did not save money and

establish a new "house" for himself, he prepared at least for the time when he might come home as a "Chazee," or Junior Partner. Such halcyon days are not altogether unknown; but they are rare enough to justify the advice which one hears so often in Mincing-lane, "Whatever you do, don't put your boy into the tea trade."

The origin of the present state of matters is too complicated to be readily explained, and is so sore a topic with those chiefly concerned that a discreet outsider prefers to leave the problem alone. But it is universally conceded that the prime factor in the depression of the Tea trade is the extreme competition which the business have developed, and the altered conditions which steam and submarine telegraphs have, *pari passu*, brought about. Contrary to the popular impression, we did not receive our first supplies of what was then known as "chaw," and drunk out of "silver porringers," from China, but from Java, which, until the Dutch obtained possession of the island, was an English settlement. The commerce in the herb could not, however, have been great, for at first, the price ranged from six pounds to ten pounds per pound. Even during the reign of Charles II and his brother, it was disposed of at from fifteen shillings to fifty shillings, according to quality, the duty payable on every gallon of the beverage sold in the coffee-houses being eightpence. In the reign of William and Mary it was further burdened with an import duty of four shillings per pound, and 5 per cent. of the value, and during the next century, when the average price was sixteen shillings, the imports mounted up to fully 200 per cent. on the value of the commoner qualities. The Tea trade was, however, in that era a comparatively small branch of commerce, being mainly a monopoly in the hands of the East India Company. It was when the consumption increased enormously, while the business of supplying the demand was not too much sub-divided, that it became and continues so remarkably lucrative. The prices were not high enough to be prohibitory, and yet were sufficiently good to permit of a handsome profit to grower, buyer, brokers, and sellers. This is no longer the case. The people who expect to live by the traffic have multiplied out of all proportion to their customers with the inevitable result that prices have been whittled down to a figure which admits of little margin. In China—so it is affirmed by those in a position to know—a suicidal attempt has been made by the native growers to recoup themselves for falling prices by more slovenly manufacture, and even by flagrant adulteration. This, at least, is the verdict of a body so well qualified to pronounce on the evidence before them as the Shanghai Chamber of Commerce. A fact even more conclusive is that, while the exports of China tea have fallen off enormously, those of the newer tea-producing districts have increased in an inverse ratio. It is known that between 1881 and 1886 the export decreased by twenty-four million pounds, while that of Indian and Ceylon teas increased by nearly thirty-five millions, and since then the disparity has been even greater. Thus, it is obviously useless for China any longer to regard herself as able to control the tea trade of the world, or to conduct herself as if she were the prime producer. She may be fortunate, indeed, if India, Ceylon, and Java leave her the second place in the struggle for supremacy.

The planters of Assam were the first to work their gardens on the principles of scientific high farming, and now they are reaping their reward. But of all the competitors who have disputed the China monopoly, Ceylon is likely to prove the most formidable, though she entered the field so recently that tea was only regarded as a likely crop when the destruction of their coffee plantations compelled the owners of estates to try other products. Now, thanks to the experience of India with which the planters began, and to the advantages of climate and soil, the export of Ceylon tea is increasing year by year, while the quality, taking one season with another, is of a decidedly high standard. These countries are, however, only two, if the two most vigorous, of China's rivals, Japan has long dealt largely in green tea, and seems determined to grow a great deal

more, now that the Western markets are open to her traders. Tong-Kiung and Cochin China are never likely to prove serious competitors for our custom, their tea being of an inferior brand. But Java is not falling behind in the race, and all the hill countries of India—Assam, Dehra-Dun, Kumaun, Darjiling, Cachar, Kangra, Hazaribagh, Chittagong, the Terai, and the Nilghiri*—are extending their operations in black tea. Natal has been demonstrated to be a tea growing region, and there are grounds for believing that the West Indies, the Southern United States, Brazil, Fiji, Australia, and even the South of Europe can produce fair marketable leaf. But there are other elements beside quality which enter into the tea-growing industry, and the first of these is cheap labour. We must remember that in India and China a labourer capable of picking and firing leaf may be had for from twopence to sixpence per day, and that it is difficult for any other countries to enter into competition with regions where a primary margin of profit is so fully ensured as in those portions of the East. It would be idle to attempt the appraisal of the different qualities of these teas. Apart from the fact that those best qualified to form an opinion rarely come to the task with a judicial mind, a great deal must be allowed for individual tastes. But most tea drinkers prefer the cheaper Indian and Sinhalese teas to the ordinary "chops" from China, while it cannot be honestly contended that, in nicety of preparation, the latter are comparable with the former. It is equally undeniable that the finer kinds of China tea possess distinctive qualities which have not yet been imitated by any other growths, and so long as Russia keeps her taste for the dearest "chops" of Congou, so long will the Flowery Land find a good market for her produce. As soon as the Siberian Railway is completed, this trade is likely to largely increase, and if ever China is wise enough to permit foreigners to set up tea-curing establishments in the interior, and to build railways, so that the present transit dues which handicap her products can be minimised, she may once more be able to hold her own in the competition.—*Standard*.

PETROLEUM ENGINES.

A correspondent writes:—

[By the following cutting from the *English Mechanic*, it would seem that these engines are not a monopoly of Priestman, as I supposed, and to which possible circumstance I attributed their excessively high cost. Let one or more of the several keenly competing local agents for Priestman's engines introduce a few specimens of Altman's, which it is devoutly to be hoped may be offered at a more reasonable price.—*Cor.*]

Petroleum motors are being simplified and improved to such an extent that they may now be ranked amongst the useful small motors. In one manufactured by Messrs. Altman & Co. of Berlin, ordinary common lamp petroleum is used with great success, and a number of these little engines, varying from 1 to 4 horsepower, have been running for over a year in different parts of Germany and Russia; whilst in Belgium a company for their construction has been formed, and the works, situated in Brussels, are in full swing. Insurance regulations constitute one of the formidable obstacles to the introduction of this class of motor in England.

REPORT ON THE NATIVE METHOD OF CULTIVATING AND CURING TOBACCO AS PURSUED BY THE RYOTS IN THE MADURA DISTRICT.

The land selected for tobacco cultivation is either liver or ash colored, or deep red, both of which are good; the former color being preferred. Great stress is laid on the quality of the well water which should be brackish. As the ryots endeavour to get as much produce out of their lands as possible, a grain crop is usually grown during September, and when this

is cut, the tobacco crop follows. Some of the ryots' however, usually retain half the area of their tobacco lands for tobacco, solely, planting the balance with combu and other grains.

Ploughing does not commence till September and is continued through the rains. This is done seven or eight times whether the soil is in condition or not; the result is that clods of unbroken earth are turned under, and the land, as a rule, is never brought into proper condition. No other implement than the native plough is used for cultivation, and the surface is merely ploughed to a depth of 3 inches. The ryots have thus no means for producing a fine tilth or for levelling the surface after ploughing.

Soon after the grain crop is cut, goats and sheep are penned on the land every night for a month or six weeks. The droppings of these animals are left exposed to sun and rain till a large area has been thus manured and are then ploughed into the soil. Some of the richer ryots collect their cowdung and place it in heaps on the field; others use this manure for fuel.

The seed-beds are merely parts of the field with little banks raised round the sides to retain the water. No attention is given to the situation of the beds as long as they are close to the well. Exposure to hot sun, wind and driving rain is not thought of. The size of the beds is usually 5' x 5' square. The surface of the bed having been worked up to a fine state with the hands the seed is scattered broadcast without ashes or any other mixture. Very little manure is used for the beds, as it attracts grubs and other insects. After sowing, the beds are worked backwards and forwards with fingers to cover in the seed. The beds are then watered from a channel connected with the well, being literally flooded to a depth of half an inch or more. This necessarily cakes the surface and but a limited number of seeds germinate in irregular patches. Germination takes place in seven or eight days. The beds are never covered and as they are watered in the early morning the hot sun by caking the soil retards the growth of the seedlings and causes many to wither away, the reasons for which are invariably put down to the wind, &c. The seedlings also naturally get much damaged by being trampled upon whilst being weeded or extracted for transplanting.

About six to seven weeks after germination the seedlings begin to show three leaves, but it is not till the leaves are 3 or 4 inches long, *i.e.*, when the plants have rooted themselves well in the soil that they are taken out for transplanting. When the plants are ready for transplanting, the beds are flooded in the morning and the plants pulled out. The seedlings being so large, hardly one escapes damage to the roots besides dragging smaller seedlings out of the soil, so that for one seedling extracted there are about four which are destroyed. The seedlings are taken out in the morning and kept in a house in a well-covered basket and transplanted in the evening.

Previous to transplanting the land is ploughed up and suitable hills and rows made up with hoes.

When planting, the channels are flooded and the seedlings inserted in much the same way as paddy is planted. The soil is often so sloppy that the plant fails to take root and in consequence withers away and dies. The tap root is very often put in bent up and I have collected as many as twenty seedlings out of a space of 30 square feet where the tap root was bent up into a curve; these plants had all died. The head ryots say, however, that they are aware of the necessity for the seedlings being firmly planted at the commencement, but owing to defective supervision their servants scamp the work.

After planting, the seedlings are watered every morning and evening till they take root. Thereafter irrigation is only conducted every other day during the morning. The snapping of the tobacco leaves may often be heard by anybody standing near the man who is guiding the water amongst the plants. Most of the work in tobacco cultivation is done in the morning, such as hoeing, topping, suckering, &c. After the whole area has been transplanted, weeds grow up plentifully. These are not removed for some

* Travancore ought to have been added.—*Ed. T. A.*

time, as some of them are eaten by the ryots and therefore left to grow for food. The soil is not touched till a month after planting. Cultivation might be commenced a fortnight earlier. The ryots say the plants would die if hoed too soon. The fact is they want the weeds for purposes above stated.

Liquid manure is applied to the tobacco plants at about five to six weeks from the time of planting. Fresh cowdung (200 lb.) is gathered each time some days previously and placed near the main channel. This is mulched with the hands into the water drawn from the well which carries the manure to the plants. This manuring is done twice.

After the plants have been settled for about six weeks, or after the first application of liquid manure, the soil is chopped and broken. This operation is again repeated when the surface becomes very hard. The ryots have no idea of the benefit derived from working the soil after each fall of rain and only appear to work their lands when it is absolutely necessary and when the soil is extremely hard. It then necessarily breaks up into lumps and is never in condition. No fresh soil is brought from one ridge to another; only one slight ridging up is given. The plant naturally are always on one side of the ridge and derive but little benefit from the water in the opposite channel.

The plants are topped when they are 2½ feet high and about seven to ten days before the bud appears. The tops are thrown anywhere and those which fall on the tobacco leaves, from their extremely gummy nature cause the leaves on which they fall to rot. Topping the plants so low induces the six or eight leaves left to spread and increase in size, and is usually supposed to be conducive to increase of weight of outturn as compared with that from plants topped higher.

The plants ripen in ninety to one hundred days, and when a few spots have appeared on the lower leaves, the plants are cut off close to the ground at about 5 p. m. These are allowed to remain exposed to the night dew, and at daybreak are gathered up and bulked into small circular heaps 2 feet high, the stalks outwards and the tips of the leaves inwards. The same evening these heaps are opened again, the plants spread out on the ground exposed to the dew and re-bulked the next morning again. This is continued till the leaves begin to turn yellow. This is usually in about five days. The plants are then hung up on horizontal poles with the stalks pressed close to each other. The stalks of the plants are slightly loosened from each other every morning all along the pole. The leaves are cured in fifteen to twenty days from time to hanging up, the colors being rusty red, yellow and green. Where the leaves have been too closely pressed together, the color is black and texture rotten. Rain destroys the color and texture, and high winds break and damage the dry leaves.

When the stems of the leaves have become thoroughly dry, although the stalks may remain green, the plants are taken down and bulked into square heaps, the stalks being laid crosswise over each other in alternate rows. These heaps are 2 feet or more in height. The leaves are not stripped from the stalks, but bulked just as they are taken from the pole. This is done in the early morning when the leaves are supple. These bulks are opened and re-bulked every two or three days. The smell issuing from a newly-opened bulk is very offensive, the stalks show signs of mould and the leaves sweat and blacken to such an extent that unless great care is taken, the texture of the leaf is entirely destroyed. When a blackish color is produced, the fermentation is finished and the leaves are stripped off the stalk and tried up into bundles of 50 leaves weighing 1½ to 2 lb. each and baled.

In many cases a mixture of jaggery and water is sprinkled on the leaves after the fermentation is over. This gives the leaves a sour fermented smell and also a fictitious texture, as they can be stretched more easily when the jaggery has soaked into them. This however disappears after a time.

The produce of one acre of tobacco cultivated in the abovementioned way ranges from 800 lb. to 1,000 lb.

The estimated cost of producing and curing this crop, based on actual observation, is as follows:—

		Expenditure.	
		RS. A. P.	RS. A. P.
Making up seed-beds and raising plants	...	0	8
Ploughing, manuring, and preparing land	...	29	0
Transplanting and care of plants up to harvest	...	52	10
Assessment on land	...	2	0
Total cost of raising the crop		84	2
Harvesting and transport to sheds	...	8	0
Fermenting and curing, scripping, baling, &c.	...	26	14
Total cost of curing the crop		34	14
Total cost of crop		119	0
Outturn.		200	0
800 lb. of leaf at 4 annas	...	200	0
Net profit per acre	...	81	0
Total	...	200	0

CEYLON TEA IN GERMANY.

(Copy). Tientsin, Bogawantalawa, Feb. 21st.

L. H. Kelly, Esq.,
Chairman of the Tea Fund Committee.

Dear Sir,—In continuation of my letters to you on the subject of tea prospects in Germany, I now send you some further remarks.

You will remember that a request for a grant of tea was sent in by me early last year on behalf of Mr. Sixtus of Bonn. It was decided, though, that, as I was shortly about to proceed to Germany myself, advantage should be taken of my visit to enquire into the prospects of tea on the Continent, and a liberal grant of tea and money was made to me for that purpose, it being understood at the time that I should only make use of the grant if I saw that some definite and permanent results were to be obtained.

After visiting Bonn, and hearing all that Mr. Sixtus could tell me, I stayed several weeks at Berlin. There I met with several people who had visited Ceylon and who were highly impressed with the good qualities of our tea, so much so that they expressed themselves anxious to see it introduced into Germany. They confirmed all that Mr. Sixtus had told me as to the disinclination of dealers to bring Ceylon tea into public notice, and this was fully borne out by the statements the dealers themselves made to me, their stereotyped reply being, that the public did not ask for Ceylon tea and that therefore they did not keep it, also that China tea suited the public taste better and was far more profitable to themselves.

The idea of a Ceylon Tea Company, importing direct, then occurred to me, and I drew up a prospectus and scheme for its establishment and working, which, although only privately circulated, was so far approved of that nearly £1,000 capital was promised. Before bringing out the Company it was felt that a certain proportion of the capital should come from the growers themselves, as being in the main the most interested in the matter. As the American Tea Company was just then in a fair way to be floated, and as its articles of association would, I knew, allow of some of its

capital being applied elsewhere than in America for pushing Ceylon teas, I hoped that on my return to Ceylon the co-operation of the Company could be secured. This however does not seem for the present possible with the limited capital which is now at the Company's disposal. On returning to England I had several interviews with Mr. Horniman, one of the largest, if not the largest tea dealer in the United Kingdom, and I proposed to him that he should take up the introduction of Ceylon tea abroad, co-operating with the Tea Fund and representing, as it were, the planters of Ceylon. I supplied him with all the information I had obtained abroad as to cost, consumption, demand and prices, but, as you will see from his letter which I enclose, he prefers like all other dealers, and for obvious reasons, to sell his own blend.

Mr. Horniman's business has just been converted into a company, and it is his intention to extend his Continental business considerably. All the large packet businesses are now turning their attention to the Continent in the hope of finding a fresh market, as their business in the United Kingdom is now very much restricted by the exceedingly keen competition at home. Travellers for English houses are now met with all over the Continent, and the advertising of tea in German papers is steadily increasing. Two or three years ago advertisements of coffee, sugar and other commodities occasionally included tea and appeared in some of the leading papers. Now almost every local paper has special tea advertisements, but so far Mr. Sixtus is the only one who has steadily advertised Ceylon tea only, and it is on this account that I now request that the grant made to me be transferred to him.

Before returning to Ceylon I spent some time with him again at Bonn and we went very fully into the matter.

As I pointed out in my original letter, he is the first who has exhibited Ceylon tea in Germany, for which he obtained the silver medal at Cologne in 1888. Previous to this he had spent a considerable sum in advertising, specimens of which I enclose for the inspection of your Committee. I also enclose specimens of his packets and pamphlets with translations. Much of his expenditure was premature and therefore not successful, but now that a demand for tea is being created by the travelling and advertising which I have previously referred to, I think that the time is just arriving when systematic advertising would be attended with good results. Particulars of the expenditure incurred and of the results obtained would be supplied through me to your Committee from time to time, and as the best illustrated papers and monthly magazines, some of which have a large circulation in America and other parts of the world, would be advertised in, Ceylon tea should gain such general publicity that the trade in Germany, and America finding a demand was springing up, will be obliged to include Ceylon amongst their other brands of tea.

In conclusion I would mention that during the last few years Mr. Sixtus has spent over R1,000 in advertisements, pamphlets and exhibition costs, and that he has only lately given up advertising, because he found that single-handed he could not afford to push Ceylon tea with the trade generally against him.

The enormous development of the packet business in England and the keen competition amongst dealers during the last 12 months have brought about results which I am confident will act most favorably in the rapid introduction of tea abroad.

It would be a good thing for Ceylon if, failing the establishment of a Continental Ceylon Tea Company, a syndicate of some of the principal tea growers could be formed, with a depot in some central spot in Germany. There are at present too many middlemen between the market in London and the consumer in Germany who pays a much higher price than is paid in England and has to put up with a more inferior article as well.

In connection with pushing tea abroad I think from what I saw of Mr. Craster in Paris and from what he told me of his efforts to introduce Ceylon tea, he has

most thoroughly deserved some assistance from the Tea Fund.—I am, dear sir, yours faithfully,

(Signed) M. BREMER.

P.S.—I give you a few figures which I took out of Mr. Sixtus' ledger as showing how the expenditure referred to has been incurred:—

Cologne Exhibition account	738.59
Advertisements and leaflets to 31st Oct. 1889	1,072.62		
to 5th January	192.80
			2,004.01
£100 say	R1,400.00

In each packet of tea Mr. Sixtus encloses a leaflet stating prices and particulars on one side, and in the reverse a short history of our tea industry taken over from Mr. John Ferguson's "Ceylon in the Jubilee Year."

He also includes a leaflet with copies of testimonials he has received, of some of which I now give the translation:—

I. If I can have 4 lb. more of your Ceylon Pekoe of which you sent me 1 lb. as sample I shall be much obliged.

II. As I had an opportunity when on a visit at your estate in Ceylon of satisfying myself as to the excellency of Ceylon tea, please send me 3 lb more.

III. Please send me 5 lb. more Broken Pekoe or if you are out of it, then of Pekoe.

IV. I was in August 1884 on your estate and brought a large quantity of Ceylon Tea back with me. This is now coming to an end, so please send me a sample of your teas.

V. Mr. M. has highly recommended your Ceylon Plantation Tea, so please send me 5 lb.

VI. I should like to have another 10 lb of the Ceylon Tea.

VII. Please send me a similar quantity again of your Ceylon Tea; it is really astonishing how much less of Ceylon Tea are requires than of China.

VIII. Back from the Melbourne Exhibition a few days ago, I had an opportunity when going and returning of tasting in Colombo excellent Ceylon Tea which I much appreciate for its quality and aroma and should like to introduce into Leipzig.

IX. Send me another lot of Ceylon Tea. Account of its excellent quality it would be well to introduce it into Germany where it is at present almost unknown.

CEYLON TEA.—Twice as strong is China, Japan &c., therefore half the price—finer flavor and aroma and contains less tannin. Silver medal Cologne. Price marks 5, 4, and 3½ per lb.

TRENTSIN ESTATE TEA.—The packet has on one side directions for use, on the other a description of Ceylon Tea as follows:—

Ceylon Tea is twice as strong and has a finer aroma and less tannin than China and Japan teas, &c.

Bogawantalawa produces the finest quality tea in Ceylon.

Ceylon Tea 2 teaspoonfuls } to ½ litre water
China Tea 4 " }

Ceylon Tea is not improved by blending with other teas and can be drunk as a self tea. The different qualities all grown on the same bush, the top leaf give Pekoe tips, the 2nd Pekoe and the third Pekoe Souchong.

Then follow full directions as to how the tea should be made.

Copy.—CEYLON TEA purchased in London and sold in packets in Germany.

Copy.—Nos. 29, 30, 31, 32 and 33, Wormwood Street, Old Broad Street, London, E. O., 30th Dec. 1890.

Dear Mr. Bremer,—In reply to your enquiry I cannot entertain your proposal about the introduction of Ceylon tea as such, as from my knowledge of trade in tea in England and the Continent it would not answer.

If you call on Mr. J. R. Manning of 9 Bridge St., Westminster, one of our Directors, he will hand you the papers you left there recently.—I am, dear sir, yours truly,
 (Signed) F. G. HORNUMAN.

GRAIN PRODUCTION IN THE EASTERN PROVINCE—It is too often forgotten that there is exported or sent coastwise (from Batticaloa to Jaffna) a good deal of paddy, the figures for which are given in Mr. Bailey's Administration Report on the Eastern Province for 1888:—

In 1885	ln.	..	100 884	bushels
1886	126,059	"
1887	111,900	"
1888	25,991	"

To which we add:—

1889 105,000 "

But besides this a great deal is now sent to Badulla district, for which we fear we cannot get any figures. There is an immense *tavalam* trade all through Bintenna and Wellassa from the sea-board. The coast rice business at Batticaloa, is now entirely in Chetty hands, and they import a great deal of rice; but it all goes to the Madulsima, Monaragala and Badulla planting districts: 131,238 bushels rice in 1888, and 107,000 in 1889 were imported. The Chetties also buy paddy of Batticaloa and have it husked by women in considerable quantities. One man has said that if machinery proves successful he will husk 5,000 ushels a month.

COUNTRIES.

THE BAMBOO INDUSTRY IN EUROPE.—This industry which originated in Great Britain, is now developing also on the Continent. Several Dutch firms have commenced the manufacture of bamboo furniture, which can be made very cheaply in Holland, as her Indian colonies abound in the raw material. That the art of making graceful ornaments and household articles of bamboo has made rapid progress in Holland, was quite recently shewn at a special exhibition of artistic furniture held at Haarlem. Two or three manufacturers are now exporting their goods to France, Germany, and England. Might not India and especially Burmah, where the Bamboo is exceptionally large and thick, take up this industry?—*Indian Agriculturist*, Feb. 8th. [And Ceylon, even more than at present. Creosoted bamboos might have an extended life in buildings. In their ordinary state they last 12 years in the bamboo houses rendered necessary by the prevalence of earthquakes in Western Java.—Ed. T. A.]

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE,

COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for March:—

NUTRITION OF PLANTS.

By

C. DRIEBERG, B.A., F.H.A.S.

The elements which plants require in order to manufacture their food are carbon, hydrogen, oxygen, nitrogen, sulphur,—these form the combustible part of plants, and are dissipated as gases either alone or in combination when the plant is burnt—and potassium, magnesium, calcium, iron, and phosphorus, which form the incombustible part of plants, and are left behind as the ash when the plant is burnt. There are also nearly always present in the ash the elements sodium, silicon, and chlorine, with frequently magnesium, and it may be other accidental elements. This latter group is not considered essential to plant life, though it performs useful functions in the economy of the plant. From the soil plants obtain by means of their roots all the metallic elements; from the atmosphere they get nearly all their carbon as carbonic acid gas, with some water and combined nitrogen. The carbonic acid gas derived from the atmosphere is decomposed by the chlorophyll cells of the plant under the influence of sunlight, the carbon being retained, and the oxygen—the same volume as was taken in in combination—being given off. The carbon, together with hydrogen and oxygen in the proportion to form water, goes to form starch which is among the earliest products formed. Thus in the process of elaboration the plant takes in carbonic acid gas and gives out oxygen: but the process of respiration is the same as that of animals, oxygen being inspired and carbonic acid gas expired. The insoluble starch is next converted into soluble glucose by the action of diastase a vegetable ferment, and is carried to all parts of the plant. The sugar is finally converted into cellulose, the material which goes to form the structure of the plant. We saw that chlorophyll was

necessary for the decomposition of carbonic acid gas, and such plants as do not contain this green colouring matter do not decompose carbonic acid gas and elaborate starch and its derivatives; such plants are the true parasites, the saprophytes and the insectivorous plants, which will be dealt with afterwards.

The formation of albuminoids is not yet fully understood, but they are supposed to be built up out of carbo-hydrates and the nitrogenous substances in the sap. The albuminoids require the elements carbon, hydrogen, nitrogen, and sulphur for their construction. The fatty matter is derived either from the carbo-hydrates or from the splitting up of the albuminoid compounds; and the vegetable acids by the oxidation most likely of the carbo-hydrates.

Experiments in water-culture in Germany,—by which plants are artificially supplied with solutions of salts in distilled water—prove that plants can get all the necessary elements of food in a mixture either of calcium nitrate with acid potassium phosphate, potassium nitrate, magnesium sulphate, ferrous phosphate, and sodium chloride; or calcium nitrate with ammonium nitrate, potassium sulphate, magnesium phosphate, and ferrous chloride.

The process of respiration in plants is best observable at night when no manufacturing of starch goes on as there is no sunlight present.

There is thus a mutual dependence of the animal and vegetable kingdoms on each other: for the carbonic acid gas which is hurtful in any quantity to animal life, is utilized in the process of elaboration by plants, which in return supply oxygen for the support of animal life: while man helps in the supply of carbonic acid gas which constitutes so important a factor in the vegetable economy.

CEYLON BEE CULTURE. III.

BY ABA.

The great family of bees is divided into two principal sections, viz., the solitary bees and the social bees. The solitary bees do not lay up stores as the social bees, but display a wonderful instinct in the construction of their nests. It is said that there are no neuters among the solitary bees, but that they are either males or females. So much for the solitary bees.

The social bees live in communities like the ants, and like them consists of males, females, and neuters or imperfectly-formed females. The social bees are subdivided into humble bees, and honey bees, which will form the subject of the future articles on the Bee.

BEES.

1, Queen; 2, Drone; 3, Neuter.

The Hive bee, or honey bee is supposed to have been introduced to Europe from the East. A bee community is said to consist of, in ordinary instances, from 10,000 to 60,000 individuals. One member of each community is a perfect female—the queen as she is called. The greater part of the life of the queen is spent in the laying of eggs for the increase of the population of the hive. The increase of population in the hive goes on at a rapid rate, the queen frequently laying 300 or more eggs a day, but the community does not increase indefinitely owing to what is called *swarming* taking place. These *swarms* found new colonies.

The impregnation of the queen takes place in the air soon after she emerges from her cell. The duration of her life is supposed to be not more than 3 years. The males only serve to propagate their species after which they are mercilessly killed by the workers as they would be useless thereafter and become a burden on the community and consume too much of the common store. The life of the workers or neuters does not extend more than a year.

The queen bee when about to lay eggs and afterwards is the object of great attention on the part of the workers. She moves about followed by about 10 or 12 attendants and lays eggs in the cells which are prepared for their reception. The first eggs laid by the queen produces workers. After these the drone or male producing eggs are laid.

INDIGENOUS FOOD PRODUCTS—
CULTIVATED AND WILD.

No. V.

BY W. A. DE SILVA.

Dipterocarpaceæ.

8 *Vateria Indica* Linn. (V. *Acuminata*, Hayne), known among the Sinhalese as the Hal tree, is a tree attaining large dimensions. It is found growing commonly in the hotter parts of the Island up to an elevation of 2000 ft. The *Vateria Indica* is a quick-growing arboraceous tree. The stem is erect and much branched towards the terminus. It is covered with a bark about a sixth of an inch in diameter, which is easily separable. The leaves are large, green, and of an oblong shape, with a pointed apex and a curved base. The flowerlets are short stalked, and have two small bracts. The stamens are numerous and short. The fruits are borne in large numbers in one season of the year; they are of an ashy yellow colour, and are of the size and shape of cocoa fruits. A flour is prepared from the fruit and used as food in various forms. The preparation of flour from the fruits requires some practice, so as to obtain it in a suitable state for food. The fruits are gathered and the outer covering or the preicarp is first removed, then an inside white mass is left. This is scraped into thin shreds by means of a piece of shell or metal indented in the form of the teeth of a saw. Sometimes this scraping is done with a thorny twig, generally of the Sing. Wé (*calamus*) creeper.

The fruit thus scraped is of a bitter taste. In some trees this taste prevails to a high degree. To get rid of this bitter character, the scraped fruit has to undergo another operation. It is placed in a tight basket, made of split rattan or reed and the mouth of the basket is covered by tying round a piece of cloth. The basket thus prepared is kept suspended in a stream of running water, where by the process of constant washing the bitterness is removed. The scraped fruit is kept in such a stream for a day and upwards according to the degree of bitterness. The flour thus prepared is devoid of bitterness and consists of a starchy matter with an admixture of powdered soft woody substances. Before being eaten, the *Vateria* flour is generally made into balls about the size of loaves and steamed on a cloth tied over boiling water. This, when used with jaggery or syrup, though in no way a commendable food, is still not bad eating. Another way in which the product is used is in the form of a conjee.

The fruits of *Vateria* cut into pieces are sometimes made into curries. Before doing this, the bitter property in them is removed by washing or boiling with water mixed with a kind of jungle leaves known as *S. Diayaweranya* (a variety of *Hedyotes*).

The bark of this tree is used in the process of obtaining sweet toddy for the preparation of jaggery and syrup. A few pieces of the bark placed in the vessel kept for the toddy prevents fermentation.

The timber of this tree is pale white and very light, hence the planks are much used in the making of

packages, and at present are largely used in the manufacture of tea-boxes. A gum resin exudes in considerable quantity from this handsome tree and is sometimes used in making a varnish. It is said that the native medical practitioners use the resin of this tree in cases of acute Gonorrhœa, and the oil obtained from the fruit and bark is locally applied in Rheumatism.

Malvaceæ.

9. *Hibiscus Angulosu*, Mast. (*Abelmoschus moschatus* Sing. Kapu-kinissa.) This is a low shrub found throughout the Island up to an elevation of 4,000 ft. but not very commonly met with. It generally grows wild in cultivated places or in rich open grounds in the vicinity of streams or ponds. The leaves are simple but divided into five lobes, having serrate margins. They are dark green and hairy on both the surfaces. The prominent veins on the upper surface of the leaf are partly of a pink colour. The axillary flowers have yellow corollas, which become reddened when faded. The sepals are five in number, but formed into one spathe, and the stamens form a tube around the style. The whole plant is covered to a more or less extent with fine hairs and possesses mucilaginous characters. The fruit is pointed and has angular sides, much in the form of Okro or Bandakkai, but smaller in size. The testa of the fully matured seeds is marked with yellow parallel lines. The fruit in its young state is used as a food material. It is made into curries and forms a mucilaginous vegetable of a rather peculiar taste much relished by some, but not in general favour. The whole plant is in repute amongst native medical practitioners as an aphrodisiac and a specific in Rheumatism.

CEYLON TIMBER TREES.

By JOHN B. DRIEBERG, L.R.C.P. & S., EDIN.

W. Ferguson's descriptive list of Ceylon timber trees, reprinted from "Ferguson's Ceylon Directory," is an exceedingly interesting and valuable pamphlet. The trees are arranged according to their natural orders, and besides the description of the wood, useful hints are given as to the best use each can be put to, with interesting local references to some of the best specimens that can be yet seen in Colombo and other parts of the Island. The information given regarding some of the more important timber trees cannot but be of interest and value to owners of large extents of forest land and to those who wish to know the best kinds of wood to be used for special purposes.

Goda-para (*Dillenia retusa*) a common and useful wood, is used chiefly for rafters in the roofs of kitchens, where it is found to be the best wood for resisting the effects of smoke and heat.

Wal-Sapu (*Michelia Nilagirica*) a large forest tree. The wood partakes of the colour and properties of Lance-wood, and is largely used by the coach-builders of Colombo for the shafts of carriages. It is exceedingly strong and elastic.

Katu-Kurundu (*Phoberos Gœrtneri*) is the tree that produces an edible fruit—a variety of *Oograssa*. The wood is very strong and elastic, and the young shoots are tied round arms of outriggers of Ceylon fishing boats to strengthen them.

Suriyagas (*Thespesia populnea*).—This is the best known timber tree in the Island, and thanks to Mr. William Ferguson, the author of this pamphlet, and late Superintendent of Works in connection with the Municipal Department, some of the prettiest avenues in Colombo are of these trees. Some fine specimens can yet be seen in the Fort, which have been planted from cuttings. The suriya trees when old are usually rotten in the centre—hollow-hearted—the result as a rule of "insidious defunction," due to some fungoid attack: so that a squall of wind may blow a good many of them or their branches to the ground. Mr. Ferguson mentions an instance where a large branch of one of these trees came down in the Fort, from the mere concussion produced by a number of road-stampers at work. The wood of the Suriya is used by the carriage builders of Colombo for constructing the greater portion of carriages, so that it is in great requisition among this class.

Hal-Mibilla (*Berrya Ammonilla*) is one of the most valuable timber-trees of Ceylon. Large quantities are exported from Trincomalee to other parts of the Island and to Madras, in which latter place it is known as Trincomalee wood, and is used for the building of the well-known *Masoola* boats. It resembles the English ash, is light, straight-grained, and though slightly pliant, is tough. It is used for every purpose for which good wood is required.

Hora-gaha (*Dipterocarpus Zeylanicus*)—"the thief tree"—is a very gigantic forest growth, but is much despised in the Island. Mr. Ferguson suggests that this wood may be used for railway sleepers, if harder and more durable woods become scarce. Major Skinner and Dr. Elliott had a section of this wood exhumed from a mass of damp earth where it was likely to be affected by white-ants or rot, having lain buried for two years, but it was found in a most perfect state of preservation.

Doon-gas (*Doona Zeylanica*)—an excellent timber tree. Forests where the Doon tree grows present a peculiar appearance from the umbrella-like heads of the trees. The Doon yields an excellent clear resin, valuable as a varnish for furniture.

Hal-gaha (*Vateria Indica*) yields the valuable piney varnish, gum resin. The wood is chiefly used to make coffins of in Ceylon. Its bark is used to keep toddy from fermenting.

Mendora (*Isauxis Roxburghiana*) is a well-known and valuable timber-tree. It yields a large quantity of gum-resin.

Divul (*Feronia Elephantum*) a hard heavy wood yielding a gum equal to gum arabic.

Beli (*Aegle Marmelos*).—The fruit useful in medicine, has laxative and astringent properties according to circumstances,

Goraka-gaha (*Garcinia Cambogia*).—The fruit is pickled and used in cookery as a flavourer.

Kana-goraka (*Garcinia Morella*)—the only tree in Ceylon that produces gamboge.

Na-gaha (*Mesua Ferrea*) the famous iron-wood tree. A hard, reddish, heavy and good wood.

Mora-gaha (*Nephelium Longanum*) produces the well-known fruit with its characteristic ethereal flavour. A useful timber.

Kong-gaha (*Schleichera trijuga*) known as the Ceylon oak. The wood is used for mortars for oil mills and such purposes.

(To be continued.)

VETERINARY NOTES.

Distemper in dogs is an affection that is perhaps more common than any other in the canine race, and particularly so in Ceylon. The term distemper is one whose application is by no means understood, as I have had occasion to discover. Dog fanciers do not seem to recognise more than one pronounced form of the disease, and it is difficult to persuade them that other symptoms than those which attend this form are indicative of the affection.

Distemper is a contagious and infectious disease, which is more apt to affect young animals, and is of uncertain duration, often proving fatal in a few hours, again running over a long period. There are five forms of it, namely, hepatic (commonly known as "yellows"), pneumonic or pulmonary, enteric, catarrhal, and nervous. In all forms of distemper very great debility occurs.

The symptoms of *hepatic distemper* are, yellow skin, eyes and tongue, due to absorption of bile into the circulation, vomition, and a laxative condition of the bowels. There is very great debility, elevation of temperature, and a tendency to shivering. Give 1 drachm hyposulphite of soda and 5 grains sal-ammoniac, keep the animal warm; do not force food, but give bread and milk, or soup without grease. When the jaundiced look disappears, administer as a tonic 5 or 10 grains chinchona. The animal should now be nursed and fed for strength.

The symptoms of *pneumonic distemper* are a quick pulse and high temperature, constipation, and laboured breathing. Foment flanks 2 or 3 times a day with hot-water, stimulate sides with linament (soft soap, 1 drachm, hotwater 8 ounces, and liquor ammonia, 1 drachm), and wrap up chest in dry flannel. The great thing is to keep the animal in a dry and warm place. Give tonics as in the first case to strengthen.

Enteric distemper manifests itself in a very lax condition of the bowels, pain, howling, a tense and drawn-up stomach. The temperature will be found high and the pulse accelerated. Give castor-oil, $\frac{1}{2}$ to 1 ounce according to size of dog; next tincture of opium 3 to 10 drops, and hyposulphite of soda as before. Foment abdomen. Give boiled milk with cornflour or starch. If bowels still loose, give 20 grains chalk, and 5 drops opium, till this condition is improved.

Catarrhal distemper begins with sneezing and shivering, and an inclination for warmth. Discharges from the eyes and nose follow, and a cough with an inclination to vomit. Keep the animal warm and dry. A dose of oil at first will do good; follow with hyposulphite of soda. Bathe the eyes 4 or 5 times a day, and if no improvement, steam for half an hour, putting 4 or 5 drops cresote or terebene in water. Treat for strength.

Nervous Distemper begins with the characteristic fits, sometimes a dozen or more in one day. The animal rolls, froths and to all appearances shows the symptoms of true rabies. Much weakness follows each fit, and often the dog will become comatose and die. Administer a big dose of oil, apply coldwater cloths to the head, keeping the rest of the body warm. The fits ought now to get weaker. Give Bromide of Potassium, 5 grains twice a day in water or food; also hyposulphite of soda.

The use of hyposulphite of soda—a germicide in this disease—in every form, must not be neglected; and where it was used from the earliest stage, and without drugging the animal with a score of medicines which anybody and everybody can suggest, I have always found it an effectual remedy.

C. D.

MILK.

Milk is said to be a natural emulsion, or a fluid containing a number of fat globules diffused throughout its substance. As these particles of fat are insoluble in water, they give rise to the opaque white appearance common to all descriptions of milk. On standing the greater portion of the fat globules rises to the surface and forms the cream. When this is removed, the fluid below, commonly called "skim-milk" is of a greater specific gravity and of a more bluish white tint. The globules of fatty matter are inclosed in little skins or shells; by violent agitation these coverings are broken, and the fatty matter collects together in the form of butter. The composition of milk varies to a great extent, being affected by the food supplied to the cow, the breed of the cow, its state of health, the treatment it receives, time that has elapsed since calving, &c.

The following is an average of eight analyses by the eminent Agricultural chemist, Dr. Voelcker:—

Water	86.84
Albuminoids	3.95
Fats	3.80
Sugar	4.60
Ash	0.81

100.00

Milk is of a slightly alkaline reaction, but when allowed to stand for some days exposed to air, it gradually begins to exhibit an increasing acid reaction, by the formation of *lactic acid* from the milk-sugar. The milk of cows is extensively used as an article

of diet both for healthy persons and invalids, and Dr. Voelker points out that the principal matter to be attended to with regard to milk is perfect cleanliness. A good supply of pure cold water is an absolute necessity. The milk will require to be cooled, the vessels to be washed, and the animals water to drink, and in all and any of these an impure supply will spoil the produce and the animals, not to speak of the dissemination of infectious diseases.

Mr. Charles Benson, M.R.A.C., of the Madras Agricultural Department, makes the following pertinent remarks about the milk supply of Madras:—"It may not be out of place to remark here that the adulteration of milk with water (if the water be good) is, after all, only a minor evil, the loss being only in the pocket. It is a far more serious matter if the milk has been obtained from a cow suffering from disease, or if the water the cow drinks, or that added to the milk, contain minute forms of organized life. Though the ill-effects of drinking the milk of a cow suffering from disease are not always apparent, especially in the case of adults, there are many well authenticated cases in which disease and death have been traced directly to the ill-effects of drinking diseased milk; chiefly amongst children who are the largest consumers of milk in its unprepared state. Recent microscopic investigations have revealed the fact that if a cow is allowed to drink impure water (and few dairy cows drink anything else in this part of India) containing animalculæ, the same animalculæ, may be found in its milk." It has been suggested that officers should be appointed to inspect the milk supplied to consumers in Madras, but mere inspection of the milk would be useless. The only effective way would be to inspect the dairy cattle and dairies, and to allow no milk to be sold except by licensed dairy men."

I leave it to my readers to suppose how far the above remarks are applicable to the milk supply of the city of Colombo. The ditches and stagnant pools of water found in the cinnamon gardens teem with millions and millions of animalculæ, and yet a drink at one of these is the only water most of the cows kept by our milkmen get. ABA.

FINE GRAINS OF CEYLON. II.

Sing: *Kurrakkan*. Eleusine Corcana.

BY W. A. DE SILVA.

This grain is largely cultivated in the dry regions of the island, and its cultivation and use is also very common in the different districts of India. In India this grain is commonly known as Rag i, and forms almost the staple food of a large number of inhabitants. The cultivation of kurrakkan is chiefly carried on in districts where the rainfall is very low and the success of the rice crop is doubtful. There are two varieties of kurrakkan known and cultivated in Ceylon, the two differing only in capacity of bearing. The kind which yields a scanty crop is known as Rila or Monkey kurrakkan, probably owing to the resemblance of the

partitions of the seed panicle to the lean fingers of the monkey tribe. The other variety of kurrakkan bears full panicles and yields a better crop. There are two seasons for the sowing of this grain, known as Yala and Maha, the seasons being regulated as those that for paddy. But the greater part of the grain is sown for Maha season, that is in August.

In general these fine grains are sown in chenas but it is not uncommon to see other lands under this crop.

The preliminary operations in the preparation are done early. The low scrub and jungle is hewn down and the whole is set fire to; after that the land is hoed and the unburnt tufts of grass are again fired on heap. This time the ashes are evenly spread on the land and the grain is scattered. After the scattering of the grain it is customary to cover the seed up by a process of hoeing. The crop is reaped in four months' time. One difficulty and waste in the reaping of kurrakkan is, that all the ears do not ripen at one time.

The ears of kurrakkan are threshed out by pounding and the grain after being winnowed and dried has to be turned into flour before using it as food in any form. The preparation of flour cannot be effected in the ordinary way of soaking and pounding in a mortar which is the common way in case of rice—as the grains are very small, about the size of mustard seed, and the outer covering is very hard. A grinding stone made of two slabs of round granite blocks is used in preparing the flour. The flour thus prepared is cooked in different ways and eaten.

Kurrakkan, though containing an appreciable quantity of nitrogenous matter, is poor in nutritive properties for want of other constituents; and owing to the difficulty of digesting. Prof. Church, in his Food Grains of India, compares the Eleusine as 1-13 as its nutrient ratio. When this grain is taken alone it is said that it does not afford sufficient nourishment for the support of a healthy population. But in spite of this, it forms the staple food in many districts of India and in some parts of Ceylon without any appreciable degeneration in those who use the article, perhaps as they do not take it alone but mix with a variety of substances. The principal reason why this grain is adopted as a food is because it grows well under unfavourable conditions and is consequently very cheap. Kurrakkan used with curd is popularly supposed among the people to be as healthy a food as any other substance. We read in Indian papers that experiments are being made with a view to introduce this grain to Europe, not for cultivation, but for the use of the poorer classes who are said to semi-starve for want of a cheap food. We cannot expect kurrakkan to be as healthy as other grains, but when the cost and comparative facilities of its production are taken into account, it will compare favourably with any other grain as a food material.

Some believe that the disease *parangi* which exists in some parts of Ceylon where kurrakkan is consumed, is caused by its use. I think it is not quite correct to

make kurrakkan responsible for the said disease, because the people who use the very grain in the neighbouring continent are not subject to it. Moreover, the grain was in use amongst the people from times far remote, whilst the disease is of recent origin, which is evidenced by the name itself.

AGRICULTURAL SUPERSTITIONS.

Seeing then that Agricultural Superstitions stand in the way of agricultural reform, we come to enquire: How are these superstitions to be done away with, or how can the work of agricultural improvement be carried on in spite of them? Is it by directly and openly denouncing them, or by remonstrating with the cultivator for clinging to these absurd notions? I do not consider either of these the best course to adopt. No amount of remonstrance or argument will prevail with the superstitious cultivator. He loves his time-honoured customs and practices too dearly to drop them in a hurry; and he must be offered in place of his superstitions something as attractive in exchange. Gradually must the rational and practical facts of Agricultural Science be introduced to occupy the place of the crude fictions of Agricultural Superstitions. A taste for the superstitious implies a taste for the curious—for something out of the common round of every day life. The instinct of ascribing results to mysterious causes implies also the instinct of accounting in some way for known results. Our aim should be to make the best of this instinct and to direct it in the proper channel. To this end we must deal with the young mind as yet not wholly trammelled with the chains of superstition and teach it the plain truths of Agricultural Science. We must trust to the school boys of today to carry their education home, and, if they cannot influence their fathers, to bring up their children in the beliefs which they have grasped. But there are those among our native cultivators who reason after this fashion:—

If this new system is an advisable one to adopt, why doesn't this Headman or that Chief take to it? They are better informed and wealthier than I. There must be some flaw in this professed improvement, if they do not take advantage of it.

It thus behoves those who command influence to set the initiative in the adoption of improved methods of cultivation, if not for their own sake, at least for that of their less enlightened and poorer brethren.

Again, it would be a serious mistake for those who have the opportunity of impressing the need of improvement in the old method of cultivation, to speak disparagingly of the latter. There is no doubt a good deal to recommend in the native method, and a radical reform is not called for: due regard must be paid to that which deserves commendation, and native agriculture must not be contemptuously spoken off as the outcome of a barbarous age—there is no warrant for this. The cultivator should be made to see how some operations which he has adhered to are borne out by scientific facts; and how others are not, and how these could

be improved upon. Put things to him in a practical way, and try to gain his confidence. The great mistake would be to appear in the rôle of the critic. We should be slow to criticise. It is only by this diplomatic policy that eventually the native cultivator will be made to adopt methods of cultivation based on scientific reasoning, and drop those found on superstition only.

EDWIN HOOLE.

Happy Valley, Haputale, 18th Dec. 1889.

GENERAL ITEMS.

The meeting in connection with the "Prevention of Cruelty to Animals" question was called none too soon, considering the frightful exhibitions of cruelty one sees every day of his life in Colombo. It is to be hoped that the conference of influential men that has lately taken place will result in placing an effectual check on every form of cruelty to our dumb friends.

Mr. M. A. Javasinghe, who passed out of the School of Agriculture last year, is at present employed in clearing a large acreage of forest-land near Nagoda, which he intends to lay under cultivation. We wish him every success in his new undertaking.

A novel implement is to be seen at work for breaking up the road for purposes of repairs in the Cinnamon Gardens. It is a powerful 'scarifier' drawn by two bullocks who seem to work without any great effort and tear up the road most effectually, doing away with the tediously slow and no doubt more costly method of pick-digging by coolies. Whoever the inventor, he deserves credit.

Mr. Muir Mackenzie who was a student at the Royal Agricultural College, Cirencester, in 1886, has been appointed Professor of Agriculture in place of Professor McCracken who has accepted an agency under Lord Crewe.

The Glasgow and West of Scotland Technical College is now inaugurating a course of lectures on Entomology, and has secured the services of Mr. J. J. F. King, a fertile writer on the subject, who is well qualified for the work of lecturing.

A statue is about to be erected in France, of the great agricultural chemist Boussingault, who died in 1887 at the age of eighty-five. Boussingault was one of the founders of scientific agriculture, and may be said to be the initiator of the systematic application of scientific principles in field experiments.

We heartily welcome "Colonia," the magazine of the Colonial College of Agriculture, Hollesley Bay, Suffolk. Judging from the first number, it promises to be a most useful and interesting publication.

We also have to acknowledge with thanks the receipt of the "Richmond College Magazine"; a little Sinhalese work on Orthography by T. Karunaratne; the first two numbers of a Sinhalese literary magazine. "Samaya Sangara;" and the Sinhalese Diary for 1890, edited by Messrs. T. W. Gunewardene and Henry Fernando.

SCHOOL NEWS.

The arrival of a new lot of chemicals has been hailed with much satisfaction by masters and students alike. When the chemical appliances, which we should not speak of yet, arrive, our laboratory will be all that could be desired.

The students brought back with them this term a few interesting mineral specimens. We were able to add to our Botanical collection a most interesting section of an abnormal stem which we were permitted to remove from among the timber lying about the Municipal store. The specimen is of *Suriya* wood, and shows five distinct stems, each with its own wood and bast and cambium-ring in the main trunk.

We are indebted to Mr. H. D. Lewis, sub-inspector of schools, Kandy, and our late head-master, for a bag of grass-seeds for trial in the Experimental grounds

The proximity of the School of Agriculture to the

Colombo Museum is a happy accident. The students have facilities for examining Geological and Botanical specimens, and easy access to the monthly scientific literature. We lately made use of the skeleton of a Ceylon buffalo for a demonstration in anatomy to the Veterinary class.

The students have elected to spend their Friday evenings in discussing agricultural and scientific subjects. This course is a commendable one and cannot but be profitable in the end.

The Paddy (mâ wi) transplanted in October is being reaped

New Orleans cotton has succeeded fairly well, considering the nature of the soil (cinnamon sand). Though the plants have not grown high, they are very vigorous and are fruiting well.

A "king yam" brought from Jaffna by a student from the north, produced a splendid bulb in cinnamon sand. The cultivation of the yam is contemplated on a larger scale, and we are indebted to Mr. M. Vayit-tianather, a Tamil gentleman, for a supply of yams for planting.

It is proposed to open a Dairy in connection with the school if sufficient encouragement be given by residents in the Cinnamon Gardens.

REMARKS.—Fields 4 and 5 from 1st January to 31st August 1888 ran almost level, so far as yield per acre went or at least within 5lb. per acre of each other, No. 5 being least. No. 5 from 15th July to end of September was all manured with an artificial mixture costing R54'62 per acre applied. From 1st October 1888 to 30th September 1889, the increase in yield over No. 4 was 195 lb. No further increase was gained during the following 3 months of 1889 as both fields were coming away from pruning, the primary and secondary flushes being almost the same, per acre, in both fields: in fact, the unmanured field had the advantage by 1 lb. per acre. In January, however, the manured field is again shooting ahead. Field 9 was all manured by end of October 1889, and by December was giving a largely increased yield. In December it gave 73 lb. made tea per acre. No. 1 and No. 1a were both pruned in August 1888: in the former the prunings were buried green; in the latter they were not. The increase over No. 1a is considerable, but I can scarcely believe that it is all attributable to the burying of the prunings. The principle in plucking adhered to all round during 1889 was to leave two full leaves on all primary shoots after pruning, and then one full leaf, till one year had elapsed, when hard plucking, on to the abortive leaf, was adopted, and carried on till the bush closed up, some 16 to 21 months, from the previous pruning. The estate being closely planted, the sides of the bushes were plucked. In many of the fields the yield was considerably affected by a severe attack of the scale insect on the stems of the bushes.

A NEW LOCAL INDUSTRY.

Messrs. H. W. Cave & Co. have just completed what is certainly a curiosity in its way, namely, a Harmonium constructed by them in their workshop here, by their native workmen, under European supervision. It is an interesting fact as showing what intelligent natives are capable of when properly directed, the tone of the instrument being equal to English-made ones, while the frame, case etc. are certainly stronger and better calculated to resist damp. Two years hence, we understand, may see this enterprising firm with a big factory employing 50 hands or so in the manufacture of organs and harmoniums!

Very little of the material is imported—in fact scarcely anything beyond what even manufacturers at home have to import, such as the ivory for keys, the reeds, &c. Messrs. Cave & Co. will make the instruments quite as cheaply as home firms, and the chances are very much in favour of their being of a better quality, as the local requirements are better known and would be better provided for. The case of the harmonium we have seen is made of teak, and the tone of the instrument is excellent. Beside these harmoniums it is also the intention of Messrs. Cave & Co. to build American organs, and in course of time we should not be at all surprised to see them manufacturing pianos, though at present they have no such intention.

THE CHEAPNESS OF QUININE.

The leading journal has been enlightening its readers on the subject of the causes which have been contributing towards enabling them to purchase quinine at the present abnormally low prices, and its issue of last Wednesday contained the following paragraph assigning the production of Ceylon as the chief among those causes:—

THE CHEAPNESS OF QUININE.—According to the annual report of the Bengal cinchona plantation and factory for the past year, part of which is extracted in the new *Kew Bulletin*, the chief cause of the extraordinarily low price of quinine and other cinchona alkaloids for some time past is the immense exportation of the bark from Ceylon. When coffee, which for a long time was the staple production of that colony, began to fail because of a disease which attacked the trees, cinchona was largely substituted by the planters for the failing staple. The following figures will give some idea of the extent to which this was done. During the year ending September 30th, 1880, 1½ million pounds of cinchona bark were exported from Ceylon to London. In 1883-4 the quantity rose to 11 million pounds, and in the succeeding year was about the same. In 1885-6 and 1886-7 the exports amounted to 15 and 14 million pounds respectively, while in 1887-8 they fell to about 11 millions. The explanation of the decline is that when cinchona began to fail from disease and depreciation in quality, the Ceylon planters turned their attention to tea with so much energy that they cut down their cinchona trees to make away for tea bushes, and not being able to hold their bark they sold it in the London market for what it would fetch. The result has been an enormous fall in price, so that the bark has been obtainable at less than the cost of production, and quinine has fallen to a figure far below anything previously heard. The export from Java has also increased in recent years. South American bark, which a few years ago was the only source of quinine, has practically been driven out of the market, and the world has been drawing its supplies of quinine from the British and Dutch colonies in Asia. "The efforts of the Governments of Great Britain and Holland to secure for their tropical subjects a cheap remedy for the commonest of all tropical diseases, have thus culminated in a more triumphant success than was ever anticipated. But this state of affairs cannot last much longer. Ceylon planters will not go on planting cinchona trees to sell their product at a loss. As a matter of fact, planting has already ceased, and the exportations are beginning to diminish. And in the course of a year or two the price of cinchona products must rise." Hence importance is attached to a new process of manufacturing sulphate of quinine, called the fusil-oil process, invented by Mr. Wood late quinologist to the Bengal Government, of which a description is contained in the same report. Mr. Wood claims that by it—(1) the alkaloids are completely extracted from the bark in a much greater state of purity, so that the final operations for obtaining pure and finished products are much simplified; (2) that the whole process of extraction can be performed at common temperatures; (3) that the appliances are all of a simple character, and therefore well suited for plantations; and, finally, that quinine can be produced at a cost not exceeding the present unprecedentedly low market price. The last point is probably that which has most practical interest for the general public.—*London Cor.*

"VANITY FAIR" ON CEYLON GEMMING INDUSTRIES.

Having triumphantly passed through the coffee crisis, which at one time threatened to involve the island in absolute ruin, Ceylon has, within the last few years, taken a new lease of prosperity. Success, as the old saying has it, begets success; and the people of the colony are now applying their minds with surprising eagerness to a big

project for developing the gem-yielding regions. According to the *Ceylon Observer*—a paper which has always shown great caution in its statements—“neither Burma, South Africa, nor perhaps any other country, yielding precious stones, under the sun, can compare with Ceylon in the conveniences offered for developing any large industry of the kind.” Of course, Ceylon has been famous for its precious stones any time during the last two thousand years, but hitherto the harvest has been reaped on no settled principles and with the most elementary appliances. But all this is to be altered before long. Real mining is to take the place of surface-scraping. Some of the old colonists have rather pooh-pooed the idea of Europeans getting the gems, even after they have been found, with coolies ready to conceal and even swallow them at every turn; but if the enterprise ever comes to the touch of practical work, it is safe to predict that Western precautions will be able to prove quite a match for Oriental cunning.

The gem-yielding country of Ceylon covers a wide region, and many experiments have been made in the central, western, and southern provinces. Among the latest was that of Sir Samuel Baker below Nuwara Eliya and Horton Plains. The natives, for generations past, have had certain well-defined favourite localities. Even so recently as in last year some valuable Ceylon stones have been “captured.” For instance, in April a large cat’s-eye, weighing 475 carats in the rough, and 170 carats after cutting, was found in Dikoya, sold by the finder for thirty rupees, and ultimately bought by a Moorish trader for 7,000 rupees, and sent to England for sale. Again, in June, a still richer haul was made, when an alexandrite, weighing over 6 lb., and of the estimated value of 500,000 rupees—roughly £40,000—was discovered at a place called Weligama.

Altogether, with its pearl fisheries, its “boom” in the tea markets, and its genuine prospects, the ancient Tarshish, whence Solomon procured his miscellaneous gifts for the Queen of Sheba, seems likely to thrive.—*Vanity Fair*, Feb. 1st.

RANCHING IN SOUTH AMERICA.

In 1885 there were 41,000,000 sheep in the States, 72,000,000 in Australia, and 100,000,000 in the Argentine Republic. We have two thirds of a sheep to every inhabitant; in the Argentine Republic there are twenty-five sheep, and in Uruguay forty sheep, to every man, woman and child. We have 40,000,000 of horned cattle, a population of 60,000,000; the Argentine Republic and Uruguay have 38,000,000 of cattle to a population of 4,000,000. In Uruguay, with a population of 500,000 souls, there are 8,000,000 of cattle, 20,000,000 of sheep, 2,000,000 of horses, or 60 head of stock for each man, woman and child. \$15,000,000 have been invested in wire fences in Uruguay alone, and more than twice as much in the Argentine Republic.

In either of these countries a cow can be bought for \$5, a steer fattened for the market for \$10 or \$12, a pair of oxen for \$25, a sheep for 50 or 60 cents, an ordinary working horse for \$8 or \$10 and a roadster for 25, a mule for \$15, and a mare for whatever her hide will bring. Mares are never broken to saddle or harness, but are allowed to run wild in the pastures from the time they are foaled until they cease to be of value for breeding, when they are driven to the saladeros or slaughter houses and killed for their hides. A man who would use a mare under the saddle or before a wagon would be considered of unsound mind.—*American Exporter*.

THE YATADERIA TEA COMPANY OF CEYLON, LIMITED.

The second annual general meeting of the Yateridia Tea Company of Ceylon, Limited, was held at the offices of the Company, 13, Queen Street, Colombo, on the 5th March inst. Mr. H. V. Masefield was in the chair, and the following shareholders were represented, viz.:—Messrs. D. Fairweather, J. H. Starey (Managing Director), J. R. Fairweather, G. J. Jameson, W. Forsyth, C. M. Gwatkin, and by proxy W. Church, G. B. Sparkes, and G. K. Deaker, and Mr. B. G. L. Bremner (Secretary). The Secretary read the notice convening the meeting. The minutes of the last annual general meeting were read and confirmed. The Report of the Directors was taken as read. It was as follows:—

The Directors have the pleasure to submit the General Balance Sheet and Profit and Loss Account for the year ending 31st December, 1889, duly audited.

The net profit on the year’s working, after writing off for depreciation, as shown by the accounts, is R8,489 93, including R2,957 46 brought forward from 1888; and the Directors, in pursuance of the resolution passed at the last General Meeting, propose that the balance of profit be written off to New Clearings and New Factory, the policy being “to develop the Estate to the extent of bringing 550 acres of Tea into bearing, and build and equip the Factory entirely out of profits.” It is hoped the present transfer will suffice for this object, though it yet remains to build the Superintendent’s bungalow.

The total tea crop was 118,805 lb. or 21,805 lb. more than the estimate. The plucking area was 322 acres, of which 150 acres were plucked only 7½ months. The yield from the 172 acres older tea was equal to 479 lb. per acre, showing improvement equal to 75 lb. per acre. The young tea promises even better results, having yielded more than 200 lb per acre in 7½ months.

Unforeseen difficulties were encountered in building the new factory owing to the peculiar nature of the only ground available for the use of water-power, involving delay; but it is expected to be in use in March. A Turbine and Piping, Jackson’s “Rapid” Roller and “Victoria” B dryer are in course of erection, the cost of these machines having been included in the accompanying accounts. Seeing that the crop of 1889 was made entirely by hand power in the temporary factory, the prices realized are satisfactory.

The amount R10,000 capital not called in the previous accounts has since been paid, and the capital is now fully paid. It will be seen from the accounts that the outlay exceeds the paid up capital (as was foretold in the last Report). It is to remedy this, and to place the Company in the strong position of Capital Account not exceeding R350 per cultivated acre with Factory and machinery, that the Company resolved last year to defer a division of profits, which nevertheless accrue to the Proprietors in the value of their shares.

The former Board anticipated returns of 20 per cent. when 550 acres are in bearing, if this policy be adhered to; and your present Directors do not regard such anticipations as improbable or excessive.

The Company’s property consisted at 31st Dec. 1889 of:—

523 acres Tea—viz.:—	{	172 acres tea in bearing, planted in 1885
		208 acres tea in partial bearing, planted in 1887
		100 acres tea not in bearing planted in 1888
		43 acres tea not in bearing planted in 1889
		820 acres forest,

Total... ..843 acres.
(only 43 were planted in 1889, instead of 70 acres, as intended).

The Crown lands lying between parts of the property were not put up for sale until January in this year, when 40 acres were purchased: some of the land applied for being withdrawn for enquiry into native claims.

The estimated Crop for 1890 is 192,000 lb., which, it is expected, may be put on boardship in Colombo for about 28 cts. per pound.

Mr. D. Fairweather retires from the Board by rotation, in terms of the Articles of Association, but being eligible offers himself for re-election.

The Shareholders will be asked to elect an Auditor for the current year.—By order of the Directors.

B. G. L. BREMNER, Secretary.

Colombo, 22nd February, 1890.

The MANAGING DIRECTOR in proposing the adoption of the report said that the statements it contained having been made as full as possible, for the information of shareholders unable to attend the meeting, there was not much to add; the actual profit on the year's working was about R12,500 including the amount written off for depreciation of machinery &c., leaving the net profit at R8,489 to be transferred to capital account in conformity with the policy determined on last year. The capital value thus conserved goes to increase the value of the shareholders' stock. It was in his opinion most desirable to adhere to the policy adopted at last meeting and keep down the capital cost per acre. The capital had all been paid up and would be more than absorbed by necessary expenditure including that on factory and machinery. It was found advisable not to open more than 43 acres in 1889 instead of the 70 originally proposed; 40 acres of crown land had been purchased, and a like amount would have been purchased to connect existing fields, but native claims had been put in to the land which delayed the matter. It was intended to bring up the planted acreage this year to 550 acres. The new factory had given trouble in its erection, but he was in hopes it would be in working order by the end of this month; the amount expended on factory as included in the accounts was R12,500; under favorable conditions he hoped there might be an interim dividend in September next. Already 32,000 lb. of tea had been made against the estimate of 192,000 lb. More than half the crop 1889 had to be entered at an estimated value for the purposes of the accounts, and the actual results since ascertained were more favourable than the estimate. No business had been done in shares below par; some had been effected as high as 20 premium.

Mr. W. FORSYTH seconded the motion, but asked for further information as to the amount required to complete the factory, and as to the cost of production for current year which he hoped would be kept within 28 cents.

The MANAGING DIRECTOR said that probably R5,000 would cover the completion of the factory and the Board fully recognised the necessity of working cheaply.

Mr. JAMESON proposed that the appointment of Mr. B. G. L. Bremner as Secretary by the Board be confirmed: the appointment having been necessary under the articles. Mr. FORSYTH seconded, and it was carried.

Mr. JAMESON submitted for the consideration of the Directors that a larger proportion of the crop should be sold locally. Mr. FORSYTH agreed when the Colombo market was favorable but did not think a hard and fast rule should be laid down.

The report was then adopted.

Mr. FORSYTH proposed and Mr. C. M. GWATKIN seconded the re-election of Mr. D. Fairweather as a Director.—Carried.

Mr. JAMESON proposed and Mr. FORSYTH seconded, and it was agreed, that Mr. John Guthrie be re-appointed auditor.

The usual vote of thanks to the chair concluded the proceedings.

THE NEW PURCHASES OF OUR BIGGEST TEA COMPANY.—We understand that the price which the Ceylon Tea Plantation Company Limited has contracted to pay for the estates recently purchased by it—viz. East Holyrood, Waverley, Tangakelly, Cameron's Land, Lochiel, Rosita and Cymru, amounting in all to 2,215 acres—is £46,500. A considerable portion of this sum is taken by the vendors in fully paid shares of the Company; and we consider the Company has made a splendid purchase in being able to secure these undoubtedly fine properties at an all round price of £21 per acre. We also learn that an issue of £10 7 per cent Preference shares in this Company is to be made shortly to the public. We hope the Directors will reserve a sufficient quantity of these for local investors, as we do not think Ceylon people could readily find a better and safer investment for their money.—Local "Times," Feb. 26th.

THE INFLUENZA EPIDEMIC.—The influenza epidemic reached Reading last week. Several of the employés of the Biscuit Factory were attacked and were obliged to be absent from business. A number of employés of the Post Office and of the Borough Police Force and in several banks were also attacked. All the greatest authorities on influenza advised the taking of quinine twice a day as a precautionary measure, and Messrs. Sutton & Sons at once adopted the suggestion and ordered between five and six hundred doses of quinine to be delivered daily for gratuitous circulation amongst their employés, who greatly appreciated this action. It has had a beneficial effect, there being very few cases in Messrs. Sutton's establishment at this busy season of the year. The epidemic is, no doubt, of a mild form in Reading and is rapidly decreasing. The Town Clerk (Mr. Day) and the Borough Surveyor (Mr. Parry) have been attacked. One or two medical gentlemen and several tradesmen have suffered from the epidemic. There is no case of influenza at the Workhouse.—*Berkshire Chronicle*, Jan. 18th. [The influenza epidemic may prove a blessing in disguise in teaching the English people the value of quinine!—Ed. T. A.]

PLANTING IN BRITISH NORTH BORNEO.—We have to acknowledge the receipt from Mr. W. D. Gibbon, Kandy, of the Report of the 14th half-yearly meeting of the British North Borneo Company with Sir Rutherford Alcock in the Chair: the meeting was a very satisfactory one indicating the strong position of the Company in the estimation of the shareholders. The laying of a telegraph cable to Singapore and the establishment of a Bank of Borneo are among projects contemplated and likely to be carried out. We have also received copy of "Memorandum on Tobacco Planting in North Borneo." This is a compilation made at the London office in December last for the information of English Capitalists. It gives a list of the existing estates in each district followed by results of sales and a good deal of information, the conclusion being as follows:—

The Directors, taking all this satisfactory progress into consideration, and in view also of the large tract of land ceded but not yet surveyed or even selected decided to raise the price of Tobacco land from \$3 to \$6 per acre, and a notification to that effect was published on the 23rd October, 1889. Whilst Tobacco land has been raised in price, the Directors, acting on Governor Creagh's advice, have offered to make free grants of from 1,000 to 5,000 acres in each Province to any individual, or company, who will guarantee the introduction and continuous cultivation of any new product, such as Pepper, Gambier, Liberian Coffee, Cocoa or Sugar. All these products have been planted experimentally, and it has been proved that the soil and climate are admirably adapted to their culture. A Liberian Coffee Estate in Marudu Bay is doing remarkably well, and planting on a large scale by a Company is under consideration.

EXPERIMENTS IN TEA CULTURE.

The article we extracted from the *Morning Post*—see page 646—on Tea Culture in the Caucasus, New Zealand and Natal is interesting as showing the wide range of climate in which the tea plant will grow but those connected with the tea enterprise in Ceylon and India have far more reason to dread competition with each other than the competition with them of planters in temperate climates. It is not so much a question of suitable climatic conditions as of plentiful and cheap labour supply, as to whether in any country or locality tea on a large and commercial scale will succeed. We have no belief that tea in the Caucasus will be more successful than it has been in the United States, where, in warm southern localities, the ubiquitous plant grows luxuriantly enough. As to New Zealand, we should doubt the suitability of climate, while we have no doubt at all that the wages question will be found an insuperable obstacle. So in all the Australian group, unless, which is improbable, the white democracy withdraws its opposition to the introduction of Indian coolies into the northern, which are the tropical, regions of the southern lands. Our good old friend Baron Von Mueller has shown that even in the latitude of Melbourne tea will grow but with labour at 4s to 8s per diem, profitable cultivation is impossible. Sugar cultivation in Northern Queensland and portions of New South Wales, was only possible by means of "Kanakas" introduced from the South Sea Islands. But the abuses of the system became intolerable, and the white labouring classes have successfully resisted all attempts to legislate for the introduction of Indian coolies. The millions sunk in sugar estates in the Mackay (Pioneer), Herbert River, Burdekin and Maryborough districts have been largely lost and successful tea and coffee culture rendered impossible where soil and climate are suitable. In Natal, too, the inevitable agitation by the white labouring classes against the competition of coolies has made head; and if cool immigration into Natal is stopped, extended tea cultivation on a large scale will be impossible—There are some errors in the interesting article we are noticing. The "wild" tea of Assam is not more robust than the China shrub: the very contrary is the case. The indigenous tea grows well in the low hot valleys of the Brahmaputra, but would not grow at the altitudes in which China tea has been grown near Darjiling. The China tea, which is still largely grown in Darjiling, is also fine flavoured. It is not to the indigenous tea of Assam but to a suitable hybrid it is giving place. The leaf of the hybrid is more pungent and its yielded in larger quantity than in the case of China.

NEW PRODUCTS AND INDUSTRIES:

ALOE FIBRE THE BEST PAYING INDUSTRY IN MAURITIUS.

A planter send us some practical hints as follows:—

"Your article on 'New Industries' brought to my mind what I thought of writing to you about before. Last month in one of your issues you had in the back page the price of 'Drugs,' and amongst other things I noticed cobwebs selling at from £35 to £40 per cwt., and

another was sarsaparilla at 6s 11d per lb. I said to myself now this must be a good thing, I'll off at once to the Peradeniya Gardens and see and get some and learn the mode of cultivation. I saw Mr. Clark who took me to see the plants, but you may imagine my surprise when I found they had only one of the former and two of the latter in flowerpots. Now why should Government not introduce these products and give them to likely cultivators or sell them as Dr. Thwaites did with the cinchona? I have seen in an estate in Matale West about 50 acres of aloes which looked to have been carefully planted, but are I believe now abandoned, belonging to the Ceylon Company, Limited. No machinery to clean fibre properly I heard. Now when I was in Colombo in July last, I met Mr. A. Hodoul from Port Louis, Mauritius, on his way to Madras to engage coolies; he told me that the aloe fibre trade was the best paying one there and they had splendid machinery for preparing it, made in France."

The Eastern Produce Estates Company, which has succeeded the Ceylon Company, Limited, has such close relations with Mauritius, that they could surely get one of the machines used there very easily and also if necessary, a superintendent for a few months to start the industry. Labour must be considerably cheaper in Ceylon than in Mauritius.

We are specially anxious to see a start made with, and a proper trial given to, the preparation of our Aloe Fibres and to the cultivation as well as preparation of other suitable kinds. There is every encouragement to a systematic trial after the pattern set—and the machinery used—in Mauritius and the Bahamas.

Now that our Cotton Spinning Mills have commenced work with every promise of success, it is pointed out how great encouragement there is—in the wealth of raw material—to the establishment of a Paper-making Mill, for the coarser papers.

The Gem and Gold Mining prospectors are still quietly at work. No reliable reports of results have yet appeared, but, so far as can be judged, everything promises well for the establishment of several Limited Companies in addition to that promoted by Messrs Delmege and Dickson. Fine gold in washing and gold visible in quartz have both been found in Sabaragamuwa—so that capitalists have the option through these Ceylon Companies of promoting Gems or Gold or Plumbago Mining and Tea Cultivation separately or all together.

TEA FOR WORKPEOPLE.

[I enclose a cutting from the *Arbroath Guide* describing a novel method of making tea known and appreciated.—*Planter*.]

EARLY MORNING TEA AT PUBLIC WORKS IN DUNDEE.

An enterprising firm of spinners and manufacturer in the West end of the city having been put to considerable inconvenience during the late cold weather by large numbers of their operatives failing to turn out at six o'clock in the morning for the day's work, hit upon a novel expedient to get every morning a full complement of hands. The morning defaulters were principally women, and the firm, knowing the weakness of the sex, arranged for supplying each female who arrived at the works in good time with a cup of warm tea before starting work. During the few days the experiment has been tried it has wrought well, and, while the old ladies especially have been delighted beyond measure with this attention paid to their creature comforts, the firm have been congratulating themselves upon their happy idea. The matter does not, however, end here. The fame of the tea has spread to neighbouring works and the females there have been loud in their demands for a like privilege. A large number of female operatives in a west end factory struck work because they had not got a satisfactory answer to their demands for hot tea in the morning.

INDIAN PLANTERS ON TEA DRYERS.

One of the Black Squad writes us:—Your South Sylhet correspondent is trying to do more than he is able, when he undertakes, as he does in your issue of the 28th January, to teach planters what dryers they should go in for. Instead of writing to one of the Calcutta Agency houses, he should have addressed himself to at least a dozen of them, and he would then have found how precious little Calcutta houses know about drying or any other kind of machines. The firm who wrote "There is little to choose between the 'Down Draft' and the 'Venetian'", evidently knew very little about the matter. The two machines are not in the same street. For quality and quantity of work, cost of erection and repairs, and amount of fuel used, the 'Down Draft' is far and away the better machine. If your correspondent wants information about drying machinery, he will get more in a week by visiting neighbouring gardens and asking the opinions of his brother-planters than all the Calcutta firms could give him in ten years. He is evidently very badly in need of information from somewhere. Fancy his saying that Jackson has machines of very much the same type or principle, as the 'Down Draft'! Fancy too, his saying that an advantage claimed for the 'Sirocco' was that it was automatic. Great Scott! When I went to school, we were taught that automatic was from the same roots as automaton, autos mats, and meant self-acting. No sane man ever went into a tea-house and saw coolies spreading mat on 'Sirocco' trays and come away with the idea that the machine was a self-acting, i.e., an automatic one.

Your South Sylhet friend says: "Every planter is only too glad to hear of anything to his advantage," and yet he abuses the "Peripatetic Planter" for pointing out to others the advantages of the "Down Draft Sirocco." I have no more interest in the Sirocco than our Sylhet *Chai* has; but as an Engineer of many years' experience, I may be allowed to say, perhaps, that I endorse every word that the "Peripatetic Planter" has written in praise of the "Down Draft." In the opinion of the majority of planters, the old No. 1 "Sirocco" is the best dryer that has yet seen the light for quality of work; but in these days of big concerns, and ten thousand maund factories, we want quantity as well as quality; and so far the A "Victoria" seems to be the only machine in the market that meets present requirements. Automatic machines are rapidly supplanting the old types, and five years hence manual driers will be things of the past. Messrs. Ransomes' new drier will, I fancy, beat the "Victoria" and "Venetian Dryers," to say nothing of Kinmond's, Gibb's, and Barry's and Sharp's; but if Messrs. Davidson & Co. will only take the bull by the horns and give us an "Automatic Down Draft Sirocco" in two sizes, turning out, say, one maund and three maunds of pucca tea per hour, it will beat all comers.—*Indian Planters' Gazette*.

PERAK TEA.

The appearance on the London market of an invoice of Perak Tea may well mark another stage in the changing conditions of this important trade. The quantity is small, indeed—only 78 half-chests; but how is it since the first sample from Ceylon excited the same interest and curiosity that Perak is exciting at the present moment? Yet Ceylon is now in a fair way of rivalling Ceylon as a contributor to the English market; while the import from India, which has commenced within the present generation, already far exceeds the quantity China is called on to supply. And, great as have been the resultant changes in the conditions of the trade, we are clearly not yet at the end of the list. Experiments are being made with the tea plant in Fiji and the West Indies. The attempt to cultivate it in the Caucasus seems likely to achieve success. The production is extending in Java, in spite of fiscal difficulties. And now the appearance of this new competitor opens up, as we have suggested, indefinite possibilities of further change. For the only question here was of quality. If palatable tea could be produced at all, on

the slopes of the range which runs down through the Malay Peninsula, the possibilities of quantity would seem practically illimitable. And on this crucial question of quality the verdict of experts seems unhesitatingly favourable. The samples offered were readily bought at a price ranging from 1s 0³/₄d. for broken pekoe down to 6³/₄d. for dust, so that the new industry may be considered fairly launched.—*L. and C. Express*.

COFFEE ON THE NILGIRI HILLS.—These Hills present various and different aspects to the coffee planter at this time of the year. While in one part the season is very backward and the spike is almost invisible, in another part it is most forward. At Kotagerry, for instance, one blossom is out and the spike is advanced. Rain just now in that neighbourhood is needed and will do much good. In other places, it will do a deal of harm, unless followed up by heavy and frequent showers.—*South of India Observer*.

GIGANTIC CHAMPAC TREES.—The latest edition of the Roorkee Civil Engineering papers, has it, that "in Mysore the champac trees obtain a girth of fifty feet; in Northern India it never exceeds sixteen feet." In which part of the Mysore Province these gigantic trees are to be seen, it does not tell us. The champac in the Lal Bagh, which is said to be over a hundred years old, is nine feet in girth; those of the Belur temple more than six hundred years old, are fifteen feet in girth; the Hidamba coil trees, at Chittaldroog, are sixteen feet in girth.—*Bangalore Spectator*.

LABOUR AND PRICES IN INDIA.—At the meeting of the Civil and Mechanical Engineer's Society held on January 8th, a paper entitled "Notes on Labour and Prices in India," was read by Mr. H. H. Parkinson, Assoc. M.I.C.E., late assistant chief engineer to the Gaekwar of Baroda. The author stated in his paper that, whereas his wages are only one-tenth, the common labourer in India does one-seventh to one-eighth the English cost. It is preferred to avoid carrying spoil more than one hundred yards, and should filling be required at a greater distance than that, a fresh excavation would be opened. The bricks in use are of very inferior quality, and vary in price from 11s to £1 per 1,000. There are three qualities of lime, burnt with coal, wood, or rubbish, costing 14s 5d, 12s 7d, or 9s 9d accordingly, per cubic yard. Brick-work may be estimated at 10s, and concreted 5s 9d per cubic yard. Timber is mostly imported from Burmah, and wood in roof trusses, etc., costs 5s per cubic foot.—*Indian Engineer*.

THE SUMATRA TOBACCO PLANTATIONS COMPANY (Limited) state in their report:—1888 Crop.—Fields 100 (acres about 130) were cultivated, and produced 79,937lb. of tobacco, which realized in Amsterdam £5,447 7s. 2d.; less cost, £3,000; showing a profit of £2,447 7s. 2d. The price obtained, viz., 1 guilder per $\frac{1}{2}$ kilo, was far lower than was confidently expected both by your directors and the vendors in view of the quality of the tobacco. Under the guarantee of the vendors that the profit on this crop should not be less than £5,000, those gentlemen have paid £2 552 12s. 10d. This £5,000 being available for dividend, to the exclusion of the shares allotted to the vendors, your directors on June 24th declared an interim dividend of 10 per cent., free of income-tax, on £25,000, equal to £2,500, and now recommend a final dividend of 9 $\frac{1}{2}$ per cent, free of income-tax, equal to £2,375; income-tax on £5,000, £125; thus absorbing the sum of £5,000. Your directors have pleasure in stating that the working of the estates is efficiently and economically carried out in every department confirming the high opinion they have entertained of the ability and energy of the administrator, Mr. A. P. Bernard.—*L. and C. Express*.

NOTES ON PRODUCE AND FINANCE.

The Chancellor of the Exchequer is not very likely to move in the matter of the tea duty, but all the same the discussion on the advantage to accrue to the tea industry by such a step is useful. A strong difference of opinion exists on the subject, and Sir Roper Lethbridge's views did not find favour at a recent meeting of the Tea Committee of the Ceylon Association in London, held on the 27th ult., at which growers, merchants, and brokers were present. The following resolution was carried by a large majority:—"That, in the opinion of this meeting, a reduction of the tea duty will be advantageous to the tea growers of Ceylon."

The organ of the tea retailers, on the other hand, says:—"Under all the circumstances, even if it were possible to grant a remission of taxes to the extent of six millions, we think it would not be desirable to take it all off tea, for the article would be free from Customs, examination, which, in our opinion, is salutary, as it is a check upon importers bringing tea of a too inferior quality into this kingdom; further, being interested in the weight of every package, the Customs' returns have always been accepted as correct, whereas, if the matter rested with the agent or the importer, a direct inducement would be given to fix the weights against the buyer's interest. . . . As regards the effect of a reduction of the duty upon the quality of the article imported, no doubt tea would suffer like other things; and as the price would be reduced to a very low point indeed, we fear the public would be educated to pay so little for it that the importation of really fine tea would stop, as it could not possibly pay either the merchant or the retailer."

Perhaps by the time there is an immediate prospect of the duty being abolished, those interested will have arrived at something like unanimity on the subject. At present, if the Chancellor of the Exchequer desired to be guided by the prevailing opinion, he would find it difficult to ascertain which way the wind blew.

Mr. Joshua Whitworth suggests in the columns of the *Grocer* that the present time seems favourable for the grocer to address himself to the cultivation and prosecution of a higher standard of tea for his customers, but he adds that the best way to do this is for the retailer to give his counterpane a small bonus on teas sold at or beyond a given price. Not a healthy arrangement this. The next step would be that some dishonest retailers (for there is occasional dishonesty even in the grocery trade) might find it more profitable to offer a bonus to his young men for obtaining a high price for an inferior tea.

Pure coffee at reasonable prices has become a scarce article of produce in some parts of London, according to the public analyst of St. Luke's Vestry, who states that, "Coffee this year proves to be the most generally adulterated article," and he adds that "there is very little chance of an ordinary customer getting pure coffee. Besides the undeclared mixtures, the vendors of which could be prosecuted, there is a mass of coffee sold under various grand titles, or in packets, on which the buyer, when he has leisure to read the printing thereon, finds in small letters somewhere, 'This is sold as a mixture.' The vendor hereby is held by most magistrates to be safe whatever the buyer may have asked or paid for. Hence, a mixture containing from 70 to 90 per cent. of chicory not unfrequently is sold for 'coffee.'"

A new company has been formed, entitled the Eastern Mortgage and Agency Company, Limited, with a capital of £1,000,250, in 100,000 shares of £10 each, and 250 founders' shares of £1 each. The first issue consists of £600,250 in 60,250 shares; 50,000 are ordinary shares of £10 each, and there are 10,000 "A" shares of £10 each, which bear the same dividend as the ordinary shares. There are also 250 founders' shares of £1 each, which will, it is stated, be allotted at par to the applicants who have provisionally applied for the whole of the ordinary shares, but no preference in the allotment of the ordinary shares will be given to these applications over those made by the public. Applications will also be received

for £100,000 terminable Four and a Half per Cent. debentures, to be issued for three or more years as may be desired, which will have interest coupons attached payable half-yearly on May 15th and Nov. 11th, at the company's bankers. The countries this company desires financially to serve are India, Burma, the Straits Settlements, &c. The directors are E. Barclay, Esq. (Messrs. Barclay, Bevan, Tritton, Ransom, Bouverie, and Co.); John E. Borland, Esq. (Messrs. Steel Brothers & Co.); George W. Campbell, Esq. (Messrs. Finlay, Campbell, & Co.); James Hora, Esq., Director of the Trust and Agency Company of Australasia, Limited; Sir Hugh Low, G.C.M.G., late British resident in the State of Perak; William Paterson, Esq. (Messrs. Paterson and Simons).—*H. & O Mail*, Feb. 7th.

PRICES FOR MAURITIUS PRODUCTS.

(From the *Merchants and Planters Gazette*, Feb. 10th.)

VANILLA.—The market is firm. We have to quote the sale of a few lots fine quality at R24 per kilo above 6 inches and Vanillons at R13.50 per kilo. We entirely maintain our last valuation as regards the outturn of the coming crop which will not exceed 12,000 to 13,000 kilos.

ALOE FIBRE.—The market is in the same situation. We have no sales to record, holders preferring to ship for their own account rather than to sell fine qualities under R400 per ton. The following quotations are nominal:—

1st quality	R375 to R400 per ton
2nd quality	R350 to R360 per ton

PLANTING PROSPECTS IN FIJI.

The possibilities of Fiji have often been descanted on; but, great as is the belief entertained in her capabilities, the test of that which may yet tend to give practical recognition to the means she possesses for the production of wealth, can be best applied by noticing what other places, having a like soil and climate, have really done in that direction to which tropical colonies must incline if their resources are to be developed.

Placing sugar on one side, and recognising that the chemist is apparently, and according to Mr. E. Knox, to be as much regarded with respect to that matter as the agriculturist and manufacturer, Fiji has established a claim to be classed as a tea-producing country. It is not to any largeness of export already in evidence, that one looks when stating this; that has yet to await realisation when the consciousness of capitalists shall be fully aroused to the fact that tea can be grown, and grown to pay. When that desideratum shall be secured, the rest will follow. But the circumstance that this is a tea country has been established beyond the suspicion of a doubt; and the operations of others, with the results of their work should be regarded, as well that planters and landowners here may not lose heart, as that it may always be borne in mind that the day must come when Fiji and her tea shall hold rank in the world of commerce and enterprise.

The fact of her capabilities in this respect has been demonstrated by the two estates which have so meritoriously earned the thanks of the community for that which they have illustrated. Working amidst very many hardships and contending against difficulties which at times have threatened to become almost insuperable, Alpha and Masusa have reached not only the stage of export but of high commendation among experts. They have done even better than this. They have found favor among tea-drinkers and secured a victory worthy of notice. It is not by any means easy to conquer tastes long established; old favorites maintaining their

place by force of habit and being proverbially hard to dislodge. But Taviuni and Savusavu have done this, and Mr. Stephens and Mr. Barrett respectively have practically, and by sheer skill, usurped the place once occupied by importations from China and have driven those out of the market. With more marked success, even, have they vanquished the Indian teas sought to be introduced, and deprived them of the footing once they bade fair to establish in our midst. This is the more noteworthy inasmuch as the Indian product is not unlike our own. So much more laudable the victory; so much more does it establish the fact that the Colony produces an article more congenial to the taste of the people; so much more does it lend strength to the reasonable hope that Australasia—whence those people come—where their taste was formed, and which is in such close contiguity to them, will not only eventually become the legitimate customers of a nearer neighbour but will contribute capital to aid the production.

Fiji has attained the knowledge that her soil can grow tea of a character not to be surpassed. The number of those who possess the requisite practical knowledge may be small; but still there are some in our midst. Land and skill are here, therefore, beyond a question. Energy is certainly not wanting; but—and here comes the rub, where is the capital. That must be found by co-operation, and by means of operations conducted on the principle of central factories. Where capital can be found, no such organizations need exist; but where it is absent, surely they may be formed by means of a little tact and expense and certainly with but little or no risk. Is there no one among the many whose land is lying idle and unproductive, to take this up practically and so to welcome fortune in place of bowing to sterile poverty.—*Fiji Times*.

MUSK SEED AND ESSENTIAL OIL.

A lowcountry planter writes:—

Some years ago I was growing the *Hibiscus moschatus*, of which I enclose a few seeds, and was always under the impression that an essential oil could be extracted from the seed, but I was never able to get a sufficient quantity to make the experiment. On reading an old *Tropical Agriculturist* the other day I observed that a Continental firm (Schimmel & Co., Leipsic) had succeeded in obtaining an oil and were much interested in this vegetable musk. Now what I want you kindly to help me in is, with regard to the present value of the seed or the oil; in former days it was sold as a seed under the head of "Grains d'ambrette." I believe you receive Schimmel & Co.'s Price Current, and if so I presume it will contain some reference to this seed or oil, as they are the parties who are chiefly interested. If you slightly bruise the enclosed seed you will perceive the odour of musk. In the days of hair powder it was used for imparting an odour of musk to the powder. As the animal musk is very expensive; Morris recommends the cultivation of this bush to the West Indian planters—but I fancy it might soon be overdone.

I was reading the other day a cutting I had made from the *Observer* some years ago (before the *Tropical Agriculturist* was started) about the pith-plant from which the sun hats are made (Sinhalese *Diya Siyambala*), and there is also reference to the jute plant which is grown so largely in India, and unknown in Ceylon; it struck me that it would be an interesting article to reproduce in the *Tropical Agriculturist*.

We referred this letter and the seed to Dr. Trimmen, who kindly writes as follows:—

The Musk-seeds sent are the produce of *Hibiscus abelmoschus* (*Abelmoschus moschatus*), a plant cultivated in most tropical countries and occasionally found apparently wild in the lowcountry of Ceylon, where it bears the same name, "kapu-kiniron," as the com-

moner and more handsome species *H. angulosus*. Your correspondent was supplied with seed from the Gardens a few years ago.

In reply to his queries, I believe that there is no export of these seeds from India, but they are imported to France from the W. Indies, chiefly from Martinique, under the name of "graines d'ambrette" and used as a substitute for musk. They are stated to fetch about 6d per lb. at Mincing Lane.

The seeds on chemical analysis have been found to contain a fixed oil and an odorous principle besides other ingredients. Messrs. Schimmel of Leipzig report that the fixed oil solidifies at 10° and on distillation is partially decomposed, the distillate containing free acetic and a fatty acid. The odorous matter, according to M. Bonastie, is a light green fluid with strong odour of musk, and is not volatile.

A SYPHON ASTONISHING THE NATIVES is thus noticed in one of the Perak district reports:—"On the 5th I went to Selebin, Mr. Taylor's mine. Mr. Treloar, the manager, has got a syphon working, which draws water from a mine 20 feet deep to the pumping shaft, about 200 feet away. I believe this is the first time that this method of drawing water has been tried in Perak, and I think it would prove of great use to the Chinese, who frequently have a deep ditch connecting their mines to the pump shaft. When this syphon was first tried at Selebin the Chinese could not make it out at all, and were greatly astonished to see water being pumped from a mine without the help of any mechanical force."

THE ORIGIN OF 'CACAO.'—In a paper by the Rev. Prof. Skeat, read at a meeting of the London Philological Society, on "The Language of Mexico; and Words of West-Indian Origin," the author says:—

It has been already noted that, in forming compound words, such a sound as *tl* is dropped, mediaily. Thus *teo-calli*, a temple, is for *teotl-calli*, lit. god-house. I see no way of accounting for our *cacao* except by help of this principle.

Cacao is merely the Spanish spelling of the Mexican word; and there is not, exactly, any such word in Mexican. The right word is *cacahuatl* or *cacauatl*, the name of the cacao-tree. Now when this word is compounded with *atl*, water, the compound becomes *cacaua-atl*, i. e., *cacauatl-water*, a drink made from cacao. Perhaps the Spaniards analysed this, in their own way, as representing *cacaua* followed by *atl*, and thus evolved a form *cacaua* (Span. *cacao*), which had no existence in the original language. Indeed the peculiar form *cacao* suggests that they probably did even worse, and got their *cacao* out of the original word *cacauatl* itself, by assuming that *atl* meant water, and so might be dropped. Either way, they dropped an essential part of the word, and adopted only a part of it.

It thus appears that the right word for *cacao*, in Mexican, is *cacauatl*, which is a simple original word according to the above-named Dictionary. In Murray's Dictionary it is resolved into *caca-uatl*, explained by 'caca-tree.' The Mexican Dictionary recognises no *uatl*, but gives the word for 'tree' as *quawtl*, which in composition becomes *quauh*, whether it precede or succeed, the word with which it is compounded. Examples are: *no-quauh*, my stick (lit. my bit of tree) *quauh-ticpac*, upon a tree; so that I have failed to verify this so far.

The word for *chocolate* presents no difficulty. The Mexican word for 'chocolate' is *chocolatl*, explained as 'aliment fait, en portions égales, avec les graines de cacao et celles de l'arbre appelé *pochoil*.' *Chocolatl* cannot be further analysed; it has no connection with *cacao*, as is usually so recklessly asserted. So that we ought to speak and write of the cultivation, prospects, &c. of the 'cacahuatl' or 'cacauatl' tree! This is worse than 'cacaoutchouc.'

REPORTS ON THE PADI (RICE) BORER, &c.

The following reports, by the Curator, Museum, are published for general information. By command, W. H. TREACHER, Secretary to Government.

Government Secretary's Office,
Taiping, 25th March, 1889.

My attention was called to this subject, by a letter dated the 1st of January, 1887, that was forwarded to me by H. M.'s Assistant Resident of Perak from Dr. Leech, the Collector and Magistrate of the Krian District, in which he says:—

"With this letter I have the honour to forward you a bottle containing some specimens of a maggot which is at present playing havoc with the padi crop here. This is the third season I have heard of its attacks, and each year has been worse than the preceding one. The time, it appears, is just as the ear is beginning to form. Many (maggots) are found in one stalk, the whole inside of which becomes brown and rotten. I have seen acres of padi attacked in this way, with the stalks and ears complete, but without a single grain of rice in them. It appears that it makes no difference whether the land is dry or wet. I have not been able to ascertain what sort of insect produces these maggots. If any method of destroying them could be got, it would be a great blessing to the people of this district, as the ravages committed by this maggot far exceed those of the rats or pigs—the other enemies of the padi crop. Perhaps the Curator of the Museum or H. M.'s Resident may know something of the habits of this pest, and suggest some means of destroying it. On the 12th January, I suggested the burning of the straw after the harvest, and Dr. Leech sent out a Malay notice recommending this course to the cultivators in his district. Since January I have visited the padi-fields, and have procured specimens of the caterpillars, which I have kept, and have bred from them the perfect insects. The results of these observations I will now proceed to detail, beginning with the description of the various stages of the Padi Borer Moth.

DESCRIPTION.

Chilo species affinis. *C. Oryzaellus* of Riley.

The egg is oval-shaped and white, faintly tinted with green. It has a finely pitted surface, with some irregular, longitudinal creases. They are laid in masses of thirty or more together, in a slanting, overlapping, double, treble, or more extended series, and are firmly cemented together and to the leaves on which they are laid. The egg is about 3-100ths of an inch long by 15-1000ths of an inch wide.

Larva.—Head dark brown, polished, furnished with a few stiff brownish hairs, a median yellowish line. Cervical shield varies from light to dark brown, with a median yellowish line. Colour of body pale yellowish white, slightly transparent, marked with five rather indistinct, pale, purplish stripes, of which those bordering the stigmata are scarcely half as broad as the other three. The piliferous spots are oval, yellowish coloured, and polished, stigmata small, transversely oval, brown, the last pair twice as large as the others; these latter are sometimes pale centered. Anal plate yellowish, polished, furnished with a row of three hairs upon each side and two near middle; it is marked with a few purplish spots.

Length 7-8ths to 1 1-10th inch. Diameter, 1-10th to 3-20th inch.

Pupa.—Colour pale yellowish brown, with five brown longitudinal stripes. As it nears maturity it assumes a dark brown colour, wing cases paler, and with a pearly lustre. Head bent forward, its front somewhat pointed. Thorax with very fine transverse stripes. Abdominal joints, armed dorsally, near their anterior margin, with numerous very minute brown thorns. Stigmata projecting. Tip of last joint conical, with a longitudinal lateral impression; expanding dorsally into two flattened projections, each being divided into two broad teeth. There are also two projections from the lower surface of the last joint, one on each side of the longitudinal impression. Length 3-10th to 6-10th inch, and diameter 3-40th to 1-10th inch.

Imago.—Male, above, general colour pale ochraceous. Anterior wings, with an irregular oblique fuscous fascia, from about the middle of inner margin to near the apex of wing. Costal and posterior margins ochraceous, fringe golden. A marginal line of seven small brown spots and a submarginal line of shining golden brown spots, along the posterior margin, but curving away from the apex. Some of these shining spots are also scattered over the oblique fuscous fascia, more thickly near the end of the cell. Hind wings paler and unmarked. Beneath, anterior wings dull yellowish, sometimes sullied the dirty brown. Hind wings the same, but only slightly tinged with brown on the costal region. Body and legs same colour as palest part of wings.

Labial palpi bushy, and slightly broadened at tip, horizontal, nearly as long as head and thorax together, a few dark scales and hairs intermixed with the paler ones. Maxillary palpi prominent, with only a few dark scales. Eyes black. Antennæ more than half the length of the costal margin of the anterior wings, filiform, clothed with pale ochraceous scales. Expanse, 7-10th to 8-10th inch, and body 3-10th to 4-10th inch long.

The female differs in being duller in colour and in the fascia on anterior wings being very indistinct. Beneath dull pale ochraceous. Labial palpi more bushy and larger than in the male. Expanse 19-20th of an inch, and body $\frac{1}{2}$ inch long.

This insect evidently belongs to the genus *Chilo* of Zincken-Sommer, and may not be specifically distinct from *C. Oryzaellus* of Riley, as the differences noticeable in it may be only of a varietal character.

A comparison with the type specimen would be necessary to determine this point. *C. Oryzaellus* is an insect of much the same habits as ours, and found in North America.

NATURAL HISTORY AND HABITS.

The eggs are laid in white irregular shaped masses, which may measure as much as $\frac{1}{2}$ inch in length, by nearly 1-10 inch in width, on the leaves of the padi plant. The eggs after a few days become greyish, from the formation of the young caterpillars inside them. In the case of one female that I reared, eleven such masses were deposited in one night, and seven the next. One mass that I counted under the microscope contained 39 eggs, so that it would be safe to say that one female will lay as many as 200 eggs. As there was not much choice possible in this case, nothing could be gleaned as to the part of the plant which would be selected, in a state of nature, by the female to deposit her eggs on, except that no eggs are deposited on the stem of the plant. Judging from the position of the young caterpillars, the part selected is at the junction of a young leaf with the stalk.

From this point, as soon as the eggs are hatched, the young caterpillars eat their way into the tender shoot or into the midrib of the leaf, in the case of the first brood, as will be mentioned further on. On exhausting the supply of food in the growing shoot, they bore out and re-enter the stalk lower down.

The caterpillar makes a nearly circular hole where it enters a stalk, which it closes up from the inside with faecal pellets and some fine white silk, and sometimes with the latter substance alone. When a caterpillar has eaten all the inner lining of one joint, or as much of it as it fancies, it either bores out again and enters another joint, usually lower down the stalk, or it bores through the substance of the joint itself. This latter method of seeking for a fresh supply of food I have seen adopted on several occasions, both in the straws picked in the fields and also in those I have kept for purposes of observation. Sometimes it is the bottom of a joint, and sometimes the top, which is thus perforated. The stalks are usually more eaten near the joints than elsewhere, and often the film remaining is so thin that the stalk breaks short off. When the caterpillar is short of food, it will feed on the inner lining of the leaf-stalks. This has happened in my breeding experiments, and I have also noticed it in the fields.

In the first brood of the season, the food of the caterpillar is principally supplied by the growing

shoot, and the interior of the midrib of the leaves and leaf-stalks. This first brood reaches maturity before any appreciable amount of hollow stalk is formed by the padi, and hence this change, in what may be considered its normal habits, is necessary, to adapt itself to its environment. The pupæ of this first brood are nearly always found in the leaf-stalks. In subsequent broods they are generally found in the inside of the stalks, sometimes above the hole of entrance and sometimes beneath it. The pupæ are usually more or less enclosed in a fine white web, and the head is, in all cases that have come under my observation, uppermost.

The larvæ are able to progress with nearly equal facility either backward or forwards, but they are not active at any time, and when disturbed generally remain quiescent.

In a single stool of young padi, I found no less than 20 caterpillars. This plant was found growing by itself in Taiping, and not near any padi fields, probably the nearest being more than two or three miles away. This seems to show either that the moths take long flights, or that some wild plant serves as food for the caterpillar as well as padi.

When kept in confinement, the moths sit quite still all day, and by preference on the earth at the bottom of the breeding cage. It seems, therefore, probable that they sit usually on the dead leaves of the padi during the day-time, and, as their colour so nearly assimilates to it, this would be a position of great security. I have hunted over a field of padi for them, but without success, though the straw was full of full-grown caterpillars and also of minute ones, and there must have been many of the moths about. In the day time, it is difficult to get them to fly, even when touched, but at night they are fairly active and seem to be able to fly well.

The female begins laying her eggs on the second night after coming out of the chrysalis, and they hatch out on the fifth day, the female dying in about seven days. The eggs seem to be all laid on the second and third night. The males, in a state of captivity, only live from three to four days. The antennæ of the moth are carried, laid back on the wings, and have to be looked closely for, or they will pass unnoticed.

Usually only one caterpillar is formed in a stalk of padi, but I have found as many as five on one or two occasions. Judging from the breeding experiments, several stalks may be required to afford sufficient food for the support of a single caterpillar.

NUMBER OF BROODS.

On the 29th April, or more than six weeks after the harvest in this district, I found in the padi stalks several minute caterpillars, as well as many more advanced; in fact, they ranged from one-eighth of an inch to full-grown ones. I also examined a young stool of padi, and found in it four or five chrysalides. This clearly shows that a brood has time to mature before the padi has begun to throw up stalks, and, taken with the presence of the caterpillars in all stages in the straw after the harvest, it is probable that these broods arrive at maturity before the harvest, and that there are three more between then and the next planting, making about six in the year. That would be two months for each generation.

NATURAL ENEMIES.

Out of one lot of four grubs raised by me, three were destroyed by the larva of some other insect, and on an examination of a padi field one day I found no less than five live pupæ and three empty cases of the same parasite, and not one single live pupa of the rice borer, and only two or three empty cases. This parasitic larva is, therefore, one of the most powerful aids in checking the increase of these destructive pests, and it would seem that, without its help, the cultivation of padi in the Malay fashion would be quite impossible.

The parasitic insect to which we are so much indebted as a fly, in appearance much like a common house-fly; and its larva is a small white maggot, which is either laid in or on the body of the rice borer, and which lives inside its body and soon destroys it.

DESCRIPTION.

Order, Diptera.		Family, Muscidae.
Tachinariæ.		Genus and Species. (?)

Larva.—Milk white and semi-transparent. Skin shiny, the anterior and posterior quarter of each segment armed with minute brown thorns. Cylindrical, with the head not distinct from body; which is abruptly terminated posteriorly and conically anteriorly. On last segment a pair of warm brown stigmata. Mouth furnished with two black hook-like organs. Length of a full-grown one, that I extracted from a dead padi borer, half an inch, and diameter, one-eighth of an inch.

The thorns on the body of the maggot are evidently the means of locomotion inside the body of its host. In two padi borers that I opened the head of the maggot was towards the tail of its host. The larva is very difficult to kill, withstanding immersion in spirits for a period of two and a half hours.

Pupa.—Cylindrical, with rounded ends, of a warm brown colour. Length 9-20th inch, and 5-40th inch in diameter.

The insect continues in the pupa state from twelve to thirteen days.

Imago.—Head silvery grey with red brown eyes and black bristles. Antennæ with three joints, of which the last is the largest, a single long hair projecting from near base of third joint. Palpi consist of a single joint. Above, thorax black with grey stripes on each side and two others on the dorsal aspect. Scutellum grey, except central portion, which is black. Abdomen black, with three silvery transverse stripes, partly interrupted on the median line. Hairs on abdomen black, conspicuous on the two last segments. Wings hyaline, iridescent, unmarked; halteres covered by large milk-white scales. Beneath wholly black, except three faint grey transverse stripes on abdomen. Legs black. Length 7-20th inch and 6-10th inch across wings; the female is a little larger.

In confinement these flies live from four to five days. I have not been able to observe the method in which the fly gets at the padi borer to lay its egg, or young, as the case may be; but it is probably when the latter leaves one joint of the stalk in search of more food that the fly effects its purpose.

EFFECTS ON THE CROP.

As I have already stated, the first brood of caterpillars matures before the rice has made any stalk, and that its food consists of the midribs of the leaves and the growing shoot. This leads to the death of those young shoots which are infested by the borer. The next brood which pass their lives inside of the stalk are those which cause the abortive ears of rice, and are, therefore, the most destructive to the crop, though the first brood killing the growing shoots of course do very considerable damage. In the letter I have already quoted, Dr. Leech has given his experience in the Krian District, and from what I have seen in Larut, nearly as much loss has been inflicted on the crops here.

PREVENTIVE MEASURES.

By the Malay way of harvesting, only the ears of the padi plant are cut, and the straw is left standing in the fields until the next planting season comes round. Hence all the caterpillars and chrysalides have an opportunity of maturing and continuing the species to the next season's crop. The perpetuation of the race from one season to another is undoubtedly carried on through the self-sown rice and the lateral shoots of the old plants, though it is possible that some large-stemmed grass may play a minor part in the matter. I found, six weeks after the harvest, in this district, that the straw was swarming with caterpillars of all ages; and I was informed by the Malays that the shoots of the old plants and the self-sown rice would continue alive until the land was broken up again for the next planting; so that food is available throughout the year for the sustenance of the successive broods of caterpillars. A consideration of these facts, as well as of the life history of the borer, leads to the conclusion that the method which is most likely

o keep down its numbers is to destroy the straw by fire as soon after the harvest as possible, and to take any measures that will tend to kill or prevent the growth of the self-sown rice between the harvest and the next year's sowing. With the efficient help which is given by the parasitic fly I have already mentioned, there should not be much difficulty in comparatively freeing the padi fields of this very destructive scourge, if the cultivators could only be induced to take a little united action.

L. WRAY, Jun.,
Curator, Perak Museum.

ADDENDA.

Since the above was written, further research has brought to light another insect associated with the one I have already described, and of almost the same habits and general appearance. In fact, so close is the resemblance that it was not until the change from the larva state took place, that I noticed any difference, except that the caterpillar was nearly uniform pale brownish pink and without the five purplish longitudinal stripes. This was unfortunate, as I did not make a close examination or take down a description of this stage of the borer. The other stages of its life were, however, recorded, and are as follows:—*Pupa*.—Colour pale brown, darker at head, tail and margins of joints, with a white bloom over the whole. Head only slightly bent forward, its front somewhat rounded. Eyes projecting, black. Thorax minutely pitted. Abdominal joints also minutely pitted, and with dark brown depressed spots scattered irregularly over them, more thickly on their anterior halves. Stigmata projecting. Tip of last joint rounded with a small projection which is produced into four sharp teeth, the two lower ones pointing downwards and the upper ones backwards. Length 6-10th inch. and diameter nearly 2-10th inch. *Imago*.—Above, anterior wings pale yellowish-brown, with a violet-brown stripe from insertion of wing to about the middle of the posterior margin, along the median nerve. This stripe broadens towards the posterior margin, which is shaded with the same colour. A distant series of five small brown submarginal spots along the posterior margin, and a spot near median nerve opposite the end of cell. Fringe, shining pale golden brown. Posterior wings silvery white, slightly tinted with yellow. Beneath, pale silvery yellowish brown; hind wings paler than the anterior ones. Head much depressed, eyes dark brown, invisible from above, thorax clothed with long hairs, ochraceous towards neck and paler towards abdomen. Thorax beneath densely clothed with long hair, as are also the two upper joints of the legs. Antennæ one quarter the length of costal margin, filiform, yellowish brown, clothed with a few short hairs. Labial palpi short, scarcely projecting beyond face. Last joint short, and clothed with close, short scales. The scales on the remainder of palpi bushy, some dark ones mixed with the paler. Expanse of wings 1 2-10th inch, length 6-10th inch.

This moth appears to have the same habits as the other species, but is not nearly so numerous in the Larut padi fields. I have only met with two examples out of the many borers I have raised, though possibly in other parts of the country it may be the more plentiful and destructive of the two. It does not seem to remain in the chrysalis longer than the other, nor is its life in the perfect state any more extended, so that any measures that would be efficacious in preventing the spread of the one would be equally applicable to the other.

L. WRAY, Jun.

SUMMARY OF THE REPORT ON THE POMELOE MOTH.

At the request of the British Resident of Perak, I made an enquiry into the cause of the destruction of all the pomeloe fruit grown in the Residency gardens at Kuala Kangsa, and have ascertained, from actual observations and breeding experiments, that it is primarily to the attacks of the caterpillars of a small moth that the loss is due.

The life history of this insect is, as far as I have been able to observe it, as follows:—The eggs are laid singly, and in small irregular patches, on the lower side of the fruit, and when they hatch out, the young caterpillars eat their way into the fruit, making a number of minute holes through the rind, generally over an area of about the size of a shilling. The pith under this patch is riddled with holes, and gum is often subsequently found, both in the cavities of the rind, and also on the outside of the fruit. As the caterpillars increase in size, they eat their way through and through the fruit, and make holes through the rind to eject refuse, and also possibly to obtain air. To these holes uneatable portions of the fruit and faecal pellets are carried by the caterpillars and ejected. The caterpillars, which are active, quick-moving insects, jump and twist when touched, and, for caterpillars, can progress with considerable speed. On arriving at maturity, they leave the fruit, and, descending to the ground, bury themselves in the earth to undergo the change into the pupa state; the caterpillars make in the earth cells of agglutinated earth, lined with white silk; they measure 0·7 inch in length, 0·4 inch in breadth, and 0·3 inch in depth. On the twelfth day after quitting the fruit the transformation is complete, and the moth forces its way through the cell and up out of the earth.

The perfect insect is about an inch across the wings and of a warm brown colour, with shadings of silvery grey. In the day-time it is very quiet, and sits usually on the earth of the breeding cages, the head and fore-part of the body being much raised, and the antennæ laid back on the wings, which are closed and folded closely over the body. When in this position, it is a very inconspicuous object, both as regards colour and form. At night it seems to be lively, and is possessed of fairly good powers of flight. The first four moths I raised all died in a little over two days, and though they consisted of two of each sex, no eggs were laid. On dissection of the females I found the eggs to be immature and few in number, and deduced from their state that the insect does not deposit its eggs until some days after leaving the chrysalis, and that during that time it needs food to enable it to perpetuate its species. With the next brood of moths I put various fruits, but none of these seemed to their taste, for though they lived for five or six days, and laid a few eggs, none of these proved fertile. In all I raised over thirty of these insects without getting one egg that would hatch. It seems quite possible that as the fruit on which they feed during the caterpillar stage is seasonal, and that there are periods of months at a time during which no food is available that the moths are long lived, and until their natural food during the imago portion of their lives is discovered, attempts at artificial breeding will be unsuccessful.

DESCRIPTION.

Egg.—Oval, dirty white, translucent, with fine raised, irregular network covering surface. Length 0·4 inch, and breadth 0·25 inch. When laid they take the form of flattened ovals with the lower side following the shape of the object on which they are laid, and the upper surface convex. *Larva*.—General colour bluish-green, tinted above with pinkish bronze. The four anterior segments being less tinted than the remainder, the young are almost wholly of a rather dull pink. Length of adult 0·86 inch, breadth 0·15 inch. *Pupa*.—General colour warm brown, darkening towards the tail, wing sheaths dull green for the first few days, after which they become dark brown. A dark median line from tail to thorax on the dorsal aspect. Length 0·5 inch, breadth 0·17 inch.

EFFECT ON THE FRUIT.

The caterpillar of the pomeloe moth is able to pierce uninjured the natural defences of the fruit. Disregarding both the pungent oil of the rind and the thick layer of pith beneath it, it reaches the cellular portion of the fruit, which it tunnels through and through in all directions, passing through the seeds if they happen to be in its line, but apparently not seeking them out. Faecal matter is deposited in

the burrows, and decomposition as a consequence quickly sets in on its walls. Under the microscope, the fluid contents of any cell which has had its containing sac broken by the passage of the caterpillar is seen to be teeming with bacterial life of many kinds. Carefully detaching a sac adjoining one that had been broken by a caterpillar, but which was in itself quite perfect, and microscopically examining its contained fluid, there appeared many bacteria, the most frequent form being masses of cocci; many other forms were present, but in smaller numbers. An oval saccaromyces was very plentiful in the injured cells, and is the probable cause of the acid fermentation which takes place in them. It was not present in the adjoining unbroken ones. Presumably the smaller forms only can pass from cell to cell through the connecting vessels. It is probably to this secondary attack of micro-organisms that the premature ripening and falling of the fruit may be ascribed, more than to the actual injury done by the caterpillars themselves; other insects taking advantage of the holes made by the caterpillars through the rind can enter the fruit and lay their eggs in the pith and pulp, with the result that large rotten patches spread from the entrance and exit holes. These insects are two or three species of flies, and a small brown beetle, all of which are attracted by any decaying fruit.

PREVENTIVE MEASURES.

The life history of the pomeloe moth shows that there is only one period of its existence when there is any hope of destroying it in useful numbers, and that is when it is in the caterpillar stage inside the fruit. The eggs are small, and so like the oil cells on which they are laid, that without a lens it is difficult to see them; in the pupa state, which is passed beneath the ground, they are well out of reach, and in the perfect stage, being strictly nocturnal and very inconspicuous, there would be little chance of doing any good. The only suggestion that I can make is to destroy all fruit that is seen to be inhabited by the caterpillars, or which falls from the trees. The destruction of the fruit which falls is of importance, not only as a means of killing the insects contained in it, but also as preventing its serving for the rearing of another brood. As the eggs seem to be laid only on the fruit itself, it would appear that if the young fruits are put into bags, that they would have a chance of arriving at maturity. I am inclined to think that the wild species of *Citrus*, known by the native name of *Umai kerbau*, and which is apparently nearly allied to the pomeloe, *Citrus decumana*, is the natural food of these caterpillars, as it is a fairly common tree in the jungles of some parts of Perak.

L. WRAY, Jun., Curator, Perak Museum.

KEW "BULLETIN."—The Kew *Bulletin* for February contains much useful information on the sugar production of the world, in a paper by R. Giffen, Esq., L.L.D., Assistant Secretary, Board of Trade, presented to Parliament in May of last year, and issued to the public in June. There are also articles on the Manufacture of Quinine in India, the use of Maqui Berries for Colouring Wine, Vine Culture in Tunis, Phylloxera in Victoria, and the Botanical Exploration of Cuba.—*Gardeners' Chronicle*, Feb. 8th.

EUCALYPTUS GLOBULUS SEEDING.—So far as we know, the fruiting of *Eucalyptus globulus* in the open air in these islands is extremely rare; but we have received lately some well-developed seed-vessels of the plant from Mr. Roberts, gardener at Tan-y-bwlch, North Wales. These were gathered from trees which were raised from seeds sown in March, 1882, planted out in the following May, and have remained unprotected ever since. They are now stately trees. That these rather tender trees stand out-of-doors and bear fruit speaks much for the mildness of the climate of the district in which they grow; but there are many other places in south-west England and Wales, and in Ireland where an equally mild climate prevails, and where *Eucalyptus globulus* and *E. coccifera* may be planted with safety.—*Gardeners' Chronicle*, Feb. 8th.

COFFEE IN NATAL.

REPORT.—To His Excellency Charles Bullen Hugh Mitchell, Esquire, Lieutenant-Colonel late Royal Marines, Companion of the Most Distinguished Order of St. Michael and St. George, Administrator of the Government in and over the Colony of Natal, Vice-Admiral of the same, and Supreme Chief over the Native Population.

MAY IT PLEASE YOUR EXCELLENCY.—We the undersigned Commissioners appointed by His Excellency the late lamented Sir George Pomeroy-Colley, by Commission, dated the 25th January, 1881, instructing us to enquire into the causes which have led to the failure of Coffee Cultivation in the Colony, and to report whether, in the opinion of the Commissioners, those causes are such as to render the Cultivation commercially unremunerative; and to make such suggestions for the removal of adverse causes, or for the amelioration of the conditions under which the Coffee planting interest has hitherto failed of success, have now the honour to report to Your Excellency that we at once proceeded to fulfil the terms of the Commission by addressing a number of questions to all persons who had been engaged in the cultivation, with a view of ascertaining to what extent unanimity of opinion existed on the various questions involved. To these enquiries, replies were received in almost every instance, and in many cases great care had been taken to afford us the fullest information, for which we have to thank the writers. We then held many meetings for the purpose of comparing and discussing the evidence, and afterwards made a tour of inspection to the principal plantations at present in work with the view of verifying, by personal observation, the statements made, and of forming a correct judgment of the present condition of the industry.

After full and careful enquiry, we have now the honour to lay before your Excellency a statement of the conclusions arrived at. In seeking for the causes contributing to failure, they are found to be so many and so various, that it can scarcely be said that they are precisely the same in any two instances; and it is necessary to bear in mind the facts that, almost without exception, those who first planted, did so without any previous experience in this or any other country, and that the plant has only been grown to any extent on the North of the Umgeni River.

In the returns given in the Colonial Blue Books, the growth of the Coffee industry should be clearly shown, as well as its decadence. The return for 1879 includes two large estates of the Natal Land and Colonization Company, which together represent two-thirds of the whole, and in the 1880 return is a large average of abandoned Coffee, off which a little was picked, as is stated by the Field Cornet of Ward No. 3, Victoria County, who says: "With respect to the increase of 503 acres in 1880, I wish particularly to note, that this does not represent a real increase to this extent in the cultivation, inasmuch as the bulk of it is represented by old and abandoned fields, which were thought unworthy to be returned in 1879, but which bore a crop of more or less value in 1880."

The evidence tends to show that trees which came into bearing prior to 1872 produced paying crops in a great majority of cases. Many persons were induced by the success attained before this date to increase their plantations to such an extent that, in some instances, pecuniary difficulties resulted, and the planters were compelled to sell their crops, and it was found that in consequence of a combination among buyers, they could not obtain more than £45 per ton, which was very much less than the price expected, and at which the syndicate afterwards sold. This was a crushing blow to many, and the trees having, as a rule, borne heavily that season, what was to be expected and seems to be the universal experience in all coffee-growing countries, happened, viz., that a heavy crop was followed by a light one. Then came the time of such scarcity of labour and high rates of wages, caused by the opening up of the Diamond Fields, that His Excellency Sir Benjamin C. C. Pine ordered out natives to harvest the crops, and the Coffee suffered most severely, it being a plant which, under the method of cultivation which was at

that time generally practised (namely, constant and heavy pruning) needs continuous labour and unremitting attention. During these years the sugar crops had been very good, with high prices, and the coffee-planters, in disgust at finding they had short crops, rooted out hundreds of acres and planted sugar.

About this time also, 1873 and 1874, it was first noticed that the trees did not bear as formerly, and this was by some attributed to a change of season and climatic conditions, and decrease in the rainfall; by others, it was suspected to arise from a deterioration in the plant itself, in consequence of the seed being planted, year after year, from the same trees, and in 1875 the Tugela Planters' Association memorialised the Government on the subject, praying that fresh seed might be imported, and in a letter accompanying the memorial stated:—"The importance of introducing fresh coffee-seed into a sub-tropical country like Natal cannot be over-estimated, as it is evident to any who understand it that our present coffee has degenerated to a great extent and become unlike the original coffee introduced; that at present it only lasts a few years (independent of diseases), whereas the originally imported trees are still healthy and vigorous; and which shows plainly enough that if we would grow coffee to pay we must be more careful where we get our seed from. The advantages to accrue from getting fresh seed into this division are more than any other; because our lands will grow plenty of coffee, but very little land is suitable for sugar. No less than 6,000 lb. of parchment seed would do, so as to give all the planters a choice of seed, and as the planters could pay at the rate of 1s. per lb., little loss will be felt by the Government, should it introduce it, as the whole community will be benefited by it. Unless such a step be taken, coffee will rapidly disappear, as each generation is getting weaker and weaker: a result which will be very disastrous to many who have invested largely in the cultivation of coffee. Considering all the peculiarities of our climate, not a berry grown in Natal should be sown for seed, but every year a small portion of seed introduced, which, in a few years, would, we hope, present a different appearance than our plantations do at the present time, and must result in giving fresh life and energy to the enterprise."

It is impossible to tell how far the practice of planting from seed grown in the Colony and then again from seed grown from the succeeding trees may have tended to reduce the vigour of the plants and to induce diseases, but it is evident that the fruit-producing power of trees planted since about 1870 is not so great as it was before that time; and further, that since then various diseases and insects, which were previously unknown here, have attacked the plant. An insect, commonly known as the borer (the same pest which killed out entire estates in Southern India), first appeared on the driest part of some estates in the northern district of Victoria County, and spread with great rapidity over the plantations north of the Umgeni; but there is no evidence to show that it has done any injury to the southward—in fact at the present time it is unknown at the Ifafa and Umzinkulu, where small and promising plantations now exist. By a strange coincidence, it appeared in the same year in Mysore, and a planter, telling his experience, says:—"The example of Ceylon planters has half ruined planting in many parts of India, and more than half ruined it in Mysore. In Ceylon there is never a month without rain, but in Mysore we have certain consecutive wet months, and many months of cloudless sky and parching winds from the North-East, which are dry, and managers of Ceylon experience, being engaged in India, obstinately refused to modify the method of cultivation suitable for one climate, when planting in another totally different, and cut down all the trees. Sufficient Ceylon planters found their way to Mysore to cause enormous loss. The planters cut down the forest, and put in coffee; then came dry seasons and sickly plants, and an insect called the borer, which aided in killing out entire plantations." He goes on to say:—"For diseases we have the borer, the bug, rat, and rot. Towards the end of 1866, in Southern India, entire plantations perished. On cutting open the dried trees, the

borer was found, and it was concluded that the borer was the sole cause of the death and the disease. The Government appointed a Commission to go after the borer, and a specimen was sent to London; but Mr. Lord came to the conclusion that the insect did not necessarily cause the death of the trees at all, as it lived on dead matter in the heart of the tree; and that the insect, guided by instinct, laid her eggs under the bark of trees; sickly and predisposed to early death. Now, although the causes could not be understood by Mr. Lord, they were clear enough to planters of experience, and I pointed out in the *Madras Times* of the 11th June, 1867, that the borer was an effect, and not a cause, and that if planters kept sickly, sapless trees, it would encourage insect life. The same thing having occurred in the larch plantations in England, the trees were pierced by the borer. It is not the insect that causes the disease, but the disease which causes the insect..... I have gone so minutely into the matter of the borer, because in Southern India a notion prevailed that it was a special plague to the coffee, rendering the possibility of an estate existing a matter of doubt. But a planter need not dread this nor dry seasons, if by judicious cropping and high cultivation, he keeps his plants in vigour."

This pest alone renders it very doubtful if it is possible to grow coffee in large plantations, on the old system, in any part of Victoria County, until some remedy or preventive is discovered. This, however, does not seem yet to have been achieved, though the Commissioners have had some suggestions on the subject. The grub is propagated by a beetle of nocturnal habits, that lays its eggs on the bark of the tree, at half an inch from the ground, which it then protects with a gummy substance that becomes hard when dry. As this is about the same colour as the bark and surrounding earth, about one-twelfth of an inch across, it cannot be seen without close inspection; and in eighteen months after the pest first becomes visible; a hole a quarter of an inch in diameter appears on the side of the tree, and the antennae of the perfect beetle protrude. During this time the mischief has been done; the egg having been quickly hatched into a maggot, and the latter having worked its way down, inside the bark, to the roots, and, after destroying the covering of these, returned up the centre of the stem and bored its way out as described.

During our tour of inspection, we found the borer on every plantation in Victoria County that we visited; and on two of the largest plantations a system was being tried of not pruning, but allowing the trees to bear three to four crops and then re-planting, as by that time they were supposed to become so injured by the borer as to be unable to bear, and to die out. The managers of these estates are very sanguine as to the probable results; and on the estate of Riet Valley, belonging to the Natal Land and Colonization Company, every possible care is evidently being taken to ensure success. We are, however, unable to give an opinion, adverse or favourable, for the present, and it would be unfair to do so, as the commercial success of this method of cultivation cannot be known for at least two years; and we look forward with great interest to the result which, if it is successful, cannot fail to have a most encouraging effect, in reviving and stimulating the cultivation of coffee in the Colony.

Among the many causes which contributed to failure, were the over-sanguine expectations entertained by the planters, founded on their great success during the first four or five years, when, in some cases, as much as 20 cwt. of cleaned coffee per acre was gathered. Whether it was a reason or not, it is impossible to tell, but the fact remains that the trees which produced these crops were raised from imported seed, or from trees of only one or two removes; and when such large crops ceased, sugar was taken up with, as at once offering a quicker return.

Another cause which, from the evidence, is considered to be important in preventing permanent success on large estates is that, coffee being a plant whose natural habitat is the hill districts of tropical latitudes, the seasons in our climate are not sufficiently marked for it, and the tree has a tendency to lose its season, or,

in other words, blossoms later in each succeeding year, and this tendency is increased by the irregularity of our spring rains. It is further to be noted that since the first cultivation of coffee in the colony the cost of labour has very materially increased.

There is clearly an impression in the minds of most persons who gave evidence that the rainfall on the Coast has very materially decreased during the past few years, more especially since the year 1872. This we do not find to be borne out by the facts. Confining ourselves to the record of observations taken at Ottawa, which is situated in the centre of the coffee-growing district, the average rainfall for ten years, namely, from 1870 to 1879, inclusive, was 38·782, but this includes the abnormal fall of 1872 of 56·71. The average for seven years, from 1873 to 1879, was 37·13; the fall in 1870 and 1871 being respectively 34·87 and 36·22; thus showing the average rainfall since 1872 to be nearly 5 per cent. more than that for 1870 and 1871, the time during which the heavy crop of 1872 was maturing. Taking also the number of days on which rain fell, we find in 1870 and 1871 92 and 87 respectively, or an average of 89·50; whereas for the seven years, 1873 to 1879, the average was 97·43. We are, therefore, unable to admit this as a fact or among the causes of failure.

Average rainfall for the seven years, from 1873 to 1879, inclusive:—

Ottawa Estate	37·13
Botanical Gardens	42·053
Pietermaritzburg	35·75

In considering the suitability of this climate for the growth of the plant, it must be borne in mind, as stated in the first part of this Report, that the coast belt in Victoria County was that only in which coffee was planted to any extent. There was a plantation near Pinetown of thirty acres, and here we were fortunate in having the evidence of the manager, a practical gardener. He states:—"Coffee being a tropical plant, and Natal sub-tropical, it is but natural to suppose that the situation for a coffee plantation must be a select one; to this I attribute my failure as a coffee planter, the plantation being in an exposed position, I do not at all attribute my failure to the soil, it was, wholly and solely, the exposed situation and dry atmosphere."

This opinion, in so far as sheltered aspect is concerned, is entirely borne out by the evidence, viz., that although much may be done by artificial shelter, yet that the aspect and position of the plantation itself are of paramount importance. In country of such character as our coast belt, it is utterly impossible to obtain such situations extending over a large connected area.

We inspected some small patches of coffee in the neighbourhood of Pinetown. The trees were 20 years old, and had not been pruned, and we were of opinion that they were as fine as any ever seen in the colony. The extent of one of these patches was about half-an-acre; the yield, three years ago, 1,500 lb. of clean coffee; the trees were since cut down to the ground, and last year bore 900 lb.; the first yield being equivalent to a return of £100 per acre in money value; the soil was a grey sandy loam, and the fields were shielded by natural aspect from prevailing winds. The borer was not found here.

Among other plantations which we visited was one of about 30 acres near the Umvati. This was owned by men who commended planting in 1860, and were very successful, having, during the whole period, kept to the one cultivation, pruning and manuring systematically from the first; their average crop was stated to be 10 cwt. per acre; they had always planted from their own seed, but even here the managing partner stated that the trees did not bear as formerly, the wood taking at least one year longer to mature. This is the only plantation we have met with which has been kept up and attended to on one method since it was first planted; in many other instances there have been years in which the trees have been allowed to go out of cultivation; sometimes the reason given was want of labour; at others, that the owners had become disgusted with one or more bad seasons,

neglected the plants, and sometimes taken up with it again. The planters referred to, in reply to the printed question as to what, in their opinion, was the cause of decrease in the cultivation, state:—"In many cases inexperience in culture, unreasonable expectations, hasty conclusions from unfavourable reports, borer ravages, and the state of the colony at the time encouraging speculations, such as the Diamond Fields, &c.;" and in reply to the question as to the conditions of future success, recommend the importation of fresh seed.

The records of all coffee-growing countries state that it cannot possibly be grown profitably, without systematic manuring from the very commencement, and that it is no use to manure after the trees begin to fail. We cannot find from the evidence, that this has been done systematically here, but planters have generally assumed that the soil had sufficient natural fertility.

On review of the evidence it is matter of surprise to find that, although the coffee plant had been cultivated in the Colony for more than 25 years, and, in some instances, to considerable profit, it is still on many points a matter of experiment as to what circumstances will ensure financial success.

The Colony being situated so nearly outside that latitude where the plant will produce at all, every little difference of soil or aspect affects it more seriously here than it would in a tropical country, and we are of opinion that large estates, as a rule, will not answer; in consequence of the impossibility of securing such a nice adjustment of circumstances, over a large area, in any part of the coast belt. On the other hand that small plantations may be cultivated with advantage, is the almost unanimous expression of opinion in the evidence, and this is borne out by what we saw during our various tours of inspection. As most farms of any extent have suitable land of a greater or less acreage, we hope to see the cultivation of coffee recommenced with the advantage of past experience, and would suggest one or two points, borne out by evidence, to those who may wish to grow Coffee in this Colony:—

First.—That the Bourbon, Jamaica, and Ceylon varieties have all done well in the past, the original plants or their immediate progeny still living, healthy trees in places. But it would be unadvisable to allow seed to be imported from Ceylon, as the leaf-disease is still very virulent there.

Second.—That the seed should be newly imported, or at most, only one or two removes from imported seed.

Third.—That the land must be of good quality, made and kept rich, by the application of manure, of which bone-dust and the produce of the cattle kraal are best.

Fourth.—That it is of no use to manure the trees after they have been allowed to become exhausted.

Fifth.—That pruning as practised in Ceylon and some other countries, is not of sufficient advantage here to warrant the expense.

Sixth.—That the aspect is of great importance, to the north of east, as nearly north as possible, being the best; southerly and westerly aspects producing wood, but little fruit.

In seeking for reliable statistics as to acreage planted during each year, we naturally referred to the returns as published in the Blue Books, but found them utterly unreliable as authorities; to wit, in the year 1866 the return is made of 3,154 acres; in 1867, 458 acres; in 1868, 2,163 acres; and 1869, 1,680 acres: whereas it is a well known fact that during these years, there was a steady and rapid increase in the extent of land brought under cultivation. Although outside the instructions in our commission, we would respectfully beg to suggest that some uniform system should be adopted for collecting agricultural statistics, in order that they may in future years form a reliable basis for reference.

In the year 1873 the returns stand at 4,800 acres, and from that time, as is well known, there has been a rapid decrease, until in 1879, a return was made of 750 acres which, we are of opinion, is in excess of the acreage in actual cultivation and bearing at the present time.

In presenting our report to Your Excellency, we cannot but feel that the mass of evidence gathered will be of great use to any person who may wish to commence the cultivation, and, although it is too voluminous, and a great deal of it too irrelevant, to print, yet we would respectfully suggest that it should be made available to any one for perusal.

There is one marked characteristic in the statements made by persons who have visited this colony, after experience in other coffee-growing countries; and it is, that the plant grows here as vigorously, in favourable situations, as they have ever seen it elsewhere. Further, we may state that, in spite of the fact of such a vast acreage of trees having been uprooted, there are patches of coffee at the present time scattered over the coast lands as healthy and flourishing as any in former years, and we fail to see any reason why, supposing the culture to have been a commercial success prior to 1872, it should not be revived again, and with the benefit of past experience and the reservations before stated, again prove a great auxiliary to the agricultural prosperity of the coast districts.

PLANTING NEWS: BATU PAHAT, Feb. 27th.—Grand news for coffee planters to see Liberian quoted at \$30 per picul. The first Johore Liberian sold in Singapore only fetched \$14 per picul. The weather is very unseasonable up here just now; showers, and heavy ones, every day.—*Straits Times*, March 4th.

DIABETES—A NEW DRUG IN ITS TREATMENT.—A writer in the *Family Doctor* draws attention to the use of a remedy in the diabetes:—The *Syzygium Jambolanum*, or *Eugenia Jambolana* is a new remedy recently introduced for the treatment of all cases of diabetes. It is found in India, Ceylon, Mauritius, and Columbia. A tincture of the powdered seeds is used in doses from three to ten drops. It has been well tested in England, Germany, and in parts of the United States. It is said to prevent the formation of sugar in the system and to stay the waste. I began its use on a marked case of diabetes some four months ago. The only case in which I have used it, Mr. M. aged 55 years, came to me emaciated, much broken down in health. He was weak, especially in his legs, and walked with a slow, tottering gait. He was voiding large quantities of urine, the specific gravity of which was 1.037. The tests showed the urine heavily loaded with sugar. I began with the use of *Rhus Aromatica*, but after a month's use I was unable to see any appreciable benefit. The patient grew weaker and the urine remained unchanged. I now gave him two fluid ounces of the mother tincture of the *Syzygium Jambolanum*, and ordered him to take three drops every three hours. After a week I ordered five drops three times a day, and parvules of iodide of arsenic three times a day. I have kept my patient on these drugs ever since. In three weeks' use of this treatment he came to me feeling much stronger, and since that time he has continued to improve in strength and gain flesh. His colour and fulness of the face has been regained to near its former appearance. He tells me that he knows he is getting well, and feels as if he could go to work. I find, at the present writing, the quantity of urine has diminished one-half; but I observe no appreciable change as yet in the quantity of sugar, though the urinometer registers 1.033. His craving for water is not so great; and he is allowed to eat most all kinds of food, with the injunction to avoid the starchy foods as much as possible. I do not flatter myself that this patient will get well, neither do I imagine that all the good result thus far are due to the *Jambolanum*; but the patient is evidently better. Let others try this drug and report.—*Burgoyne, Burbidges & Co.'s Price Current.*

SALMON FISHING IN SCOTLAND.—Salmon fishing on most of the rivers in Scotland opened on February 11th. Some good takes were made by net in the upper reaches of the Tay, the Bellmore and Pithchry station yielding 50. On the Deveron some hauls yielded 20 beautiful clean fish, and a total of 130 were landed, as compared with between 20 and 30 last year.—*European Mail*, Feb. 14th.

HEWAGAM KORALE: PLANTING.—There are now several extensive coconut and cinnamon estates in the district Lenawatte, about 300 acres in extent, belonging to Mr. Daniel, Superintendent of Minor Roads, is looking exceedingly well. Kesbewe estate, formerly belonging to the late Charles Silva Mudaliyar, and now the property of Mr. Richard Silva, sub-inspector of schools, though smaller in extent than Lenawatte, being only 80 acres, is much better soil. These being still young plantations, how long they will keep up their fertility remains to be seen. Then there is Gebenuwale estate (cinnamon and coconut), a gift to the daughter of Mudaliyar Charles Silva by her grandfather, the late Mr. Philip Perera. This is in excellent order, is over 100 acres in extent, and brings in an income of over £100 a year from its cinnamon alone; the coconut plantation not having come into bearing. Besides these nearer Colombo, there are the cinnamon estates of Messrs. Whittall & Co., which are released out.—*Cor.*, local "Times."

ON PEARLS.—A writer in the *Gentleman's Magazine* for January gives information which would lead one to expect a good market for the products of our next Pearl Fishery:—

Pearls have been rising in value in the European market so long, and threaten to rise so steadily, that they may soon become the costliest, as they have long been the most elegant, ornaments of a beautiful woman.

"Si douce, si douce est la Marguerite!" sang the ancient Provence troubadour. Many a jewel is fifty times as effective: the ruby is richer in colour, the diamond is brighter, gold and silver are more plastic—as full of possibilities as Reynard's bag of tricks. The pearl has but its mild satin skin, like an angel's shoulder, its rounded curves; yet its shy, moony lustre seems to have a more permanent hold over a dainty fancy than many a more vivid and more robust material. True, it is mere carbonate of lime; and its globing form comes but from the sickness of an invertebrate; its colours are drawn, not from the living fish, but from its putrescence after death. As ornament that owes its existence to nothing but disease and decay certainly draws little from sentiment; and perhaps the pearl owes more to its constant association with noble pictures of beautiful women than to its intrinsic glory. For all that, the decorative position of pearls is quite unassailable. In spite of their grim origin, a necklet of fine pearls remains a far more refined and dainty ornament than one of brilliants. Perhaps one reason is the presence in pearls of beauty without brilliancy.

Varieties in Pearls.—The same writer tells us that the highest known cost of a single pearl is said to have been paid by Tavernier at Catifa in Arabia. It was oval, spotless, two inches long, and its price was £110,000. A very fine British pearl—we might have a more regular British supply, I suppose, with a little more self-command, and a grain more national pride—has found a resting place in the Crown of England. It came from the Conway. These finds, however, are very rare here. Scotch pearls, when fine, fetch a good price. They wear a faint pink blush, which Parisians run after greedily. The Oingalese pearls are the whitest, but whether white, pink, black, or straw-coloured, there must always supervene that peculiar translucent finish or "water," with more or less iridescence, which, like the bright colours on Roman glass, seems inseparable from the action of buried gases. Without this the pearl is of little or no value, and is termed a "blind" pearl, like those small pearlkins we often find within half-swallowed oysters at table. You might find a big "blind" pearl, worth nothing, in your mouth, which properly tinted by the bitter essences in the putrid stack, would be worth a fortune.

COCONUTS AND TEA SEED.

There seems to be a great future for our coconuts; and what with the many uses to which they are put locally and the demand for them from outside for various purposes, the supply will never exceed the demand. At one time, coconut oil was in general use for lighting, but kerosine proved a dangerous rival. It commended itself only through its cheapness, and now it is generally used in every village. With the extension of the manufacture of coconut butter in Germany, and desiccated coconut, copra, oil, nuts, &c. exported from here, the use of the oil in calming troubled waters, and of the fibre in caulking the sides of men-of-war, the product is destined to perform wonders. And it is well that it should prosper, for there is hardly any other product in the Island which is so great a boon to the poor. Coconut butter is said to possess more nutritious constituents than genuine butter, and is in some respects better than that article; but here in its native place the value of coconut butter is not yet recognised, though the nut is largely used in food. I have heard it credibly stated, that sifted coir dust is exported from Ceylon by some merchants, since late. They, no doubt, have some good use for it, and will make fair profits out of it. Why is coir dust not valued here so much? For there is no reason why it should not be used for various purposes; for improving lands, as bedding for cattle, and, not the least, it might be advantageously used more largely by the Municipality in latrines. Dry coir dust is very light, and its absorptive power very great. If dry coir dust is used for strewing in stables, cattle sheds and latrines, it will afterwards prove of high manurial value.

We hear of a new use for tea seed. It is said that Estate coolies extract an oil out of it and use it for burning. With the dry tea twigs for his fuel, and tea seed for his oil, Ramasamy will have a good time of it. But Appuhamy, instead of using his oil from cocout, domba, and kekuna, is resorting to kerosine, and in some instances is said to be cutting down his kekuna trees to be sold for fuel! W. A. D. S.—Local "Examiner."

THE JAVA AGRICULTURAL COMPANY will be established in Amsterdam with a capital of f.2,500,000, of which f.1,500,000 will be offered here in shares of f.1,000 at par on the 7th instant, f.1,000,000 being already taken up. The object of the company is the working of the existing sugar-manufactories Bandjardawa, Bagoë, Djabong, Pesantren, and Pening, and of the coffee-lands Kroewoek and Rataredgo. These possessions were the property of Mr. G. von Bultingsowen, who died recently, and which were, since 1885, under the management of the Netherlands India Agricultural Company, which will represent in future the Java Agricultural Company in Java, and to which the shipment and sale of produce continues to be charged. The company may also issue a bonded loan of f.2,600,000, bearing interest at the rate of 5 per cent, and redeemable within thirty years. The transfer of all the manufactories and coffee undertakings takes place at a value of f.4,000,000, including all assets and liabilities, while of the bonded loan f.1,000,000 is reserved as working capital for the undertakings. According to the prospectus the total profit of all the undertakings is estimated at about f.500,000. The charges in India and Holland will be f.20,000; for interest and redemption of the bonded loan f.1,62,000 will be required; 6 per cent dividend, or f.150,000, will be paid to the shareholders, while of the remaining 50 per cent will be reserved, being thus f.84,000, and the other f.84,000 will be divided, of which shareholders will receive the half, viz., f.42,000—thus in all 7½ per cent of the paid-up capital. The director will be Mr. N. P. van den Berg.—*Cor., L. & C. Express, Feb. 7th.*

Dr. J. A. VOELCKER, Consulting Chemist to the Royal Agricultural Society of England, who is now on special duty in India, returned this morning to Madras after a visit to the Madura, Coimbatore, Salem and Nilgiri Districts.—*M. Mail.*

GEMMING OPERATIONS IN RAKWANA.—Last week Messrs. Barrington Brown and Harding were at Rakwana, inspecting all the trial pits. They also inspected the pits worked by the natives and the gems found therein. Mr. Brown wishes the work of the trial pits to be pushed on with as little delay as possible, and he wants the pits to be worked both day and night, as is done in the deep pits that are being worked by the natives. The work of the pit on Depedene estate that was suspended for some time has been resumed. Both Messrs. Brown and Harding are testing the bottom "illan," and with this view they have given instructions to spare neither money nor labor, but to push on with the works as expeditiously as possible. At the other end of the district, Messrs. Fahey and Armitage are busily engaged in sinking a trial pit on Lauderdale estate, where the work is being pushed on vigorously, but they have not yet touched the "illan." Messrs. Brown and Harding after inspecting the works of the several gem pits that are worked on Golden Grove, Botiyatenne, Fernlee, Depedene, &c., and making necessary arrangements for further operations, left Rakwana on the afternoon of the 13th inst., for Ratnapura. Mr. Barrington Brown has taken notes of the depth of the pits at which the "illan" is found, the thickness of the "illan" and the different kinds of clay and gravel that are met with in each pit. During his stay at Rakwana, Mr. Harding purchased a few gems, but none of great value. While Mr. Brown was in Rakwana, the native gemmers admired the way in which he tested the trial gem pits, and they entertain a high opinion of his skill as an expert. The first visit of Mr. Brown to Rakwana having been in the company of the Government Agent, W.P.—the Hon. Mr. F. R. Saunders—and his brother, he fortunately secured the services of an excellent overseer in the person of Mr. Simon Mendie, who is an experienced gemmer, besides possessing considerable local knowledge and influence, while he can, at any time, command any number of skilled labourers. On the other hand, the work performed by another European Syndicate has not been satisfactory; they use a new kind of washing tray and these do not at all answer the purpose for which they are intended. The trays have such a large mesh that gems of the weight of about 6 carats and less are washed away with the sand. The other day, when the trays were being tried in one of the pits sunk by the Syndicate, all the gems were washed away with the exception of a few large tourmalines. On the same day, there having been a heavy shower of rain, a few of the natives who were curious to see the result of the washing proceeded to the spot, where the washing had taken place, and were lucky enough to come across one or two good gems. Mr. Brown is now in Ratnapura inspecting properties, buying gems and curious stones, and I hear engaged in making notes for his report. Mr. Harding, left Ratnapura last week by pada-boat on his way to Colombo. Mr. Gow, after inspecting some gemming lands and tea estates, left Rakwana on the 14th for Colombo. Mr. Baddeley is now at Rakwana, having arrived here on the 14th instant. He has opened pits both at Balangoda and Ratnapura. Mr. Fahey has opened one plumbago pit and two gem-pits in the vicinity of Lauderdale estate. The workmen have not yet touched the "illan" of any of these pits. A friend of mine tells me that when he was in the Haputale district he heard of coolies finding small bits of gems in the ravine close to the store on Kelburne estate, as also on the 18-acre clearing of Oakfield estate. Should any enterprising person sink gem-pits on those lands, my informant has no doubt that they would be amply rewarded. It is said that there is a plumbago vein close to Nahavilla estate store; the sides of the river running through Gampola village also show signs of land containing plumbago and gems. A public sale of gems is to take place at Rakwana on the 26th instant, when I hear that several gems of great value will be put up for sale.—Local "Times."

THE SIKKIM AND BHUTAN CINCHONA PLANTATIONS.

The 27th annual report has reached us and will be found on page 696. From the summary in the Resolution of the Government of Bengal we quote as follows:—

The plantation was visited during the year by a severe hailstorm, which completely destroyed thousands of young plants in the nurseries and injured even the larger trees.

The total number of cinchona trees of all sorts on the plantations was 4,810,231, two-thirds of which are pure quinine yielders. The crop of the year, which was the largest ever harvested, amounted to 373,100 pounds of dry bark, of which 207,460 pounds were red, 128,770 pounds *Ledgeriana*, and 36,870 pounds of other sorts. The whole of this crop was, with the exception of a small quantity supplied on indent or sold to Government institutions, made over to the febrifuge factory for disposal.

The outturn from the factory, which is regulated by the demand, was 8,575 pounds, of which 2,191 pounds were of sulphate of quinine and 6,384 pounds of cinchona febrifuge. The total outturn for the previous year amounted to 7,250 pounds. The issues during the year fell from 8,039 pounds in 1887-88 to 7,489 pounds in the current year.

An account of the method of manufacturing pure sulphate of quinine by a process recently discovered in the Government Factory at Mungpo, together with a brief history of its invention, was published in the *Calcutta Gazette* of the 28th March 1888. This, Dr. King now points out, was incomplete, inasmuch as it did not allow to Mr. C. H. Wood, formerly Quinologist in the Plantation, sufficient credit for his share in the conception and perfection of the new process. Dr. King has appended to his report a memorandum prepared by Mr. Wood, which gives a fuller account and history of the invention. The Lieutenant-Governor fully endorses Dr. King's opinion of the value of Mr. Wood's services in this matter, and he is glad to take this opportunity of recording his appreciation of Mr. Wood's action, which has been marked by an evident desire to place at the disposal of Government the knowledge and experience which he has acquired by careful and laborious experiments in England. The Lieutenant-Governor is also glad to acknowledge Mr. Gammie's successful efforts in applying the new invention to manufacture. It is satisfactory to find that no less than 2,191 lb. of pure sulphate of quinine were prepared in the first year of its manufacture by this new process.

The revenue derived from the sale of the febrifuge sulphate of quinine, seeds, plants, and barks amounted to R1,29,160-3, against R1,37,511-3-8 in the previous year.

The net profit on the year's working amounts to R27,844.

The Lieutenant-Governor's thanks are again due to Dr. King and Mr. Gammie for their efficient management of the Department. The other Assistants are well spoken of.

In view of the reduction in price of quinine which has taken place, Dr. King is justified in holding that the efforts of the Governments of Holland and Britain to secure for their tropical subjects a cheap remedy for the commonest of all tropical diseases has proved a more triumphant success than was ever anticipated.

THE SISAL INDUSTRY IN THE BAHAMAS.

We have been favoured by a well-informed correspondent in the Bahamas with some samples of the Sisal hemp grown in that colony, accompanied by a long and interesting account of the progress and prospects of the new industry. Sample lots of fibre from the Bahamas have been recently sold in London at the high figure of 50/ 15s a ton, but this, of course, is rather excessive. At the price of 25/ a ton a very wide margin for profit will be left to the producers, so that it really seems as if the sanguine calculations of the Bahama people in

regard to their new in lustry have every prospect of realisation. As we have previously mentioned, the new industrial economy in the Bahamas has been largely brought about through the energy and foresight of Sir Ambrose Shea, the popular Governor of the islands, who has been working away with most admirable zeal and enthusiasm since he was sent to Nassau to promote the interests of the colony. During the past twelve or fourteen years the Sisal industry has been keenly followed in Yucatan, and the titles of the vast fortunes made in that country lately are almost too remarkable to be true. The stories seemed so incredible that Sir Ambrose Shea sent a Commissioner over to see how much truth they really did contain, and the reports he subsequently received fully confirmed the statements. Previous to the arrival of Sir Henry Blake—Sir Ambrose Shea's predecessor—the Sisal had been a cordially-despised plant in the Bahamas. Like the troublesome *Buthurst* burr in the Australian Colonies, the Sisal was regarded as a nuisance in the Bahamas, and various efforts—individual and organised—were made from time to time to eradicate it. The tenacity of the plant, however, appears to be amazing, and like colonial sheepskin affixed by bee-wax, as the song says—

The more you try to pull it off
The more it sticks the faster.

The more determined the Bahama people became in their efforts to root out and destroy the noxious Sisal, the more that vigorous plant held its ground, till the islanders abandoned the task in despair, and the Sisal became to the Bahamian what the rabbit is to the Australian—an inevitable, irremovable pest. It is not surprising, therefore, that when Sir Ambrose Shea's Commissioner returned from Yucatan with a full corroboration of the seeming fairy tales respecting the fortunes made from the Sisal cultivation there should have been some little incredulity in the Bahamas, more especially as the Yucatan plant was described as being inferior in many important respects to the despised product to the islands. In fact, the fibre produced from the Sisal grown in the Bahamas is much superior and worth a good deal more than the Yucatan article. The esteemed correspondent who favours us with particulars from the Bahamas anticipates—not without very good foundation, we feel sure—that a great success will be realised when the industry comes into full working order, and that the exports of the Colony, instead of being, as at present, about 130,000/ a year, will in a very short time be counted by millions. It seems strange that a plant which 2 years ago was viewed as a pestilential weed should now be universally regarded as a means of lifting the Colony into a high state of prosperity, changing the place from a hopeless condition of depression into one of bounding advancement. The price of the Crown lands in the Colony has already been raised from 5s. to 16s. 8d. an acre, and from present appearances it seems probable that the Governor will soon find it necessary to sell no more. Sir Ambrose appears, indeed, to be exercising a good deal of forethought in dealing with the altered condition of affairs in his Colony, and recognising that the population must soon be largely augmented, he wisely proposes to retain land enough to give standing room to immigrants later on. He has made reservations to enable him to make peasant proprietors on easy terms of all heads of families who are now without land, and who are to pay 5s an acre out of their first fibre crop, when they will get a grant of land free. This is for the very poorest, who have no present means to purchase. If these people, who are by no means an insignificant number, were deprived of all share in a state of general prosperity it is thought that their natural discontent would operate injuriously on large cultivators, so that, reflectively as well as directly, the policy seems to be an exceedingly wise one. It is indeed more than this, for it aptly illustrates the wisdom of choosing Governors of the Shea stamp for our smaller and undeveloped Colonies. The thoughtful and paternal way in which Sir Ambrose maps out his economic legislation for rich and poor alike is deserving of the highest commendation.

The total cost of producing this valuable fibre reaches from £10 to £12 a ton, which shows at once the immense profits which are possible. The plant takes about three and a half years after planting before the leaves are ripe, but when that stage has been reached an annual crop can be obtained for about fifteen years from the same plant, without any cost but a small one for weeding. The Sisal grows best on hard, arid-looking ground which seems to forbid the thought of possible vegetation, and of course manure of any kind is to be avoided. When the leaves are cut, the process of stripping them and getting the fibre ready for shipment will not take more than 24 hours in a climate like that of the Bahamas, where sunshine is always the order of the day. Sir Ambrose Shea has been basing all his calculations on Yucatan experience, and certainly the Bahamas are in no way behind that country in essential conditions. The planting began in the Bahamas in real earnest last May, but it has been somewhat retarded through the want of plants, so that only 3,000 acres have so far been brought under cultivation. Considering the persecution which the Sisal had undergone in the islands, it is somewhat noteworthy that any plants were found at all, and but for its marvellous tenacity it must long since have disappeared. But the plants fructify fast, and, being now under a hospitable dispensation, their cultivation will of course increase rapidly. In 1892 the first substantial exports will begin, and then the increase of export will be a progressive one. The Colonists are beginning to talk of their future prospects as if they were a present reality, but the whole economy partakes so much of the nature of an exact science that they are doubtless justified in their somewhat dogmatic predictions. In looking at these glowing prognostications of future wealth and prosperity in the Bahamas, it is not unreasonable to inquire for a moment whether the Bahamians are making sufficient allowance for the influences of the competition that may be awakened by their example. From all we can learn on the subject, however, there are but few places in the West Indies which possess the special conditions of soil and climate which belong to the Bahamas. Most of the other islands have too rich a soil, which would develop much leaf, but little fibre. This, at any rate, seems to be the opinion of Mr. D. Morris, of Kew Gardens, a gentleman who is peculiarly well informed on the fibre question.—*Colonies and India.*

CEYLON UP-COUNTRY PLANTING REPORT NUTMEG KAPOK CINCHONA BARK.

NUTMEG cultivation is getting more extended and more believed in. The days are passed when impatience at the slow growth of the tree led to its being pulled up; or when a man going to inspect an estate with the view to purchase, ignored thousands of nutmeg trees as having no value at all. Now they have not only a present but a prospective value, and a property with a decent number of nutmeg trees in bearing has a something which is independent of the fluctuations of the tea market, and would be a useful auxiliary in a time of stress. The manuring of one's nutmegs has led to a revolution of ideas in regard to that spice; there is not now that weary waiting for growth, which wore out the patience and the interest as well. Then you heard of twelve and fifteen years as the time which might be expected to run before any return would appear. With these ideas current the European world almost as soon think of investing in a teak clearing, which is said to take eighty years to grow to full size, and fifty more to mature. Now however you hear of nutmeg trees blossoming at five and fruit appearing at the sixth year. In the lowcountry shade has been found to be very desirable, a light checkered one;—but it is less called for higher up although in the early stages of growth even there the shade is grateful. Manur-

ing has worked wonders to the nutmeg, and has placed it on a firm basis, within the range of practical planting.

Another somewhat despised product is "KAPOK," and for this there are opening up extensive markets all over the world. Rotterdam and Amsterdam are free to absorb of this produce a great deal more than Ceylon can at present supply, not to speak of London and the Australian Colonies.

Lastly there is CINCHONA BARK, which has been despised and rejected for many a day. Orders are now out from home to buy, but nothing rash has been done as yet: the intending buyers being evidently careful to avoid encouraging anything like enthusiasm or the belief that cinchona bark is worth anything at all. PEPPERCORN.

JAVA COFFEE.—The reports from Java regarding the Government coffee crop are very deplorable, owing to the late heavy rains and violent storms by which fearful damage was done to the trees. According to a telegram of the Governor-General dated Jan. 20th the estimation of the Government crop was 583,458 piculs, while on Feb. 7th the Governor telegraphed a quantity of 189,440 piculs. The difference caused a great surprise, and the Home Government wired to Java for information. A telegram received in reply confirms the small crop, and reports that the quantity mentioned on Jan. 20th was that of the complete crop of 1889. With regard to the private crop the reports are all extremely discouraging, the first estimate being one-third of the former production, but this seems now to be rather excessive. Under the circumstances the prospects for Java agriculture, of which coffee is one of the chief products, are very unsatisfactory, and very prejudicial to the Java banking and other institutions. The price of coffee is in fact very high, but the quantity to be harvested too small to compensate the loss. According to official figures the Government crop of coffee in Java during the last five years was as follows:—1889, 583,458 piculs; 1888, 565,500 piculs; 1887, 428,700 piculs; 1886, 719,000 piculs; and in 1885, 1,316,000 piculs. The difference of the year 1885 compared with the estimation of 189,440 piculs for 1890 it will be seen is enormous.—*L. and C. Express*, Feb. 21st.

COFFEE.—There is as much difference between one kind of coffee and another as there is between chalk and cheese, though the uninitiated think coffee is coffee all the world over. The kind of plant that is finding most favour at the present time among those who are trying to push forward the industry, is the Coorg species, because it is a hardy plant, bears well and is cultivated without much difficulty. Those who have kept to their first love, and stuck to the chick coffee have done so with great advantage to themselves and benefit to the district, and yet chick coffee is a caste that nobody now thinks of planting. There must be a reason for this. Experienced planters tell us that it has straight upright branches, is a very sparse bearer, but that when it can be induced to give a crop it produces the berry which put Mysore coffee into the front rank in the London market. Cannon's high priced Mysore is from the old Mysore chick trees: and year after year the produce defies competition as to quality, and holds the first place. It requires thick, very thick, shade, with only a few openings to admit the rays of light and heat. It is not, however, found to pay, as when the trees are old, they bear only once in three or four years, so that the quality in a commercial sense does not make up for quantity. A tree well suited for shade for coffee is the silver oak, and it is a wonder it is not more largely used. It is easily cultivated, agrees with coffee, throws a considerable deposit of fertilising matter, is a good barrier against wind, and cattle will not destroy it. The latter consideration is a great point gained since cattle often do a deal of mischief.—*Bangalore Spectator*,

HOW TO INTRODUCE CEYLON TEAS INTO RUSSIA.

To have Russia as a buyer of our teas is an aim worthy of the best efforts of our Ceylon Tea Fund Committee; for not only do its people consume large quantities of tea, but Russian buyers are prepared to pay full prices if they can get the article they want. It will be in the remembrance of many of our readers how when the China market opened last year, such high prices were paid by the Russian agents for all the fine teas that were for sale that the English buyers were unable to compete with them. As a consequence there was a scarcity of fine teas for a time in London, and those Ceylon estates which laid themselves out for producing teas of the highest grades benefited thereby.

If there is one thing which the Ceylon tea growers are prepared to affirm more than another it is that their teas cannot be beaten anywhere, and that if their finest qualities were put against the best that China can produce, Ceylon should not suffer in the comparison. If then we could only get some of those Russian buyers who assemble yearly at the China tea ports and are ready to pay almost any price for teas which suit them, to come to Colombo and test what can be done here, we have a strong belief that we should be able to keep them to the Ceylon market in the future. As it is, our efforts to catch the Russian tea dealers or market, have been but paltry and unworthy of the Colony. When we think of the scope which Russia offers for the consumption of our principal product, and that, if secured, her market could not fail to assure us of paying prices for many years to come, it is certainly worth both sacrifice and effort on the part of Ceylon planters to get a footing there. The commercial interests of any English Colony is, of course, nothing to the Russian: the aim, indeed, of the Russian autocrat is to make his magnificent Empire self-contained, so that its wants may be supplied within its own borders, and not require to seek anything beyond. This very likely is the explanation of the planting of tea in the Caucasus—an industry, however, never likely to produce much result. In the meantime, at any rate, tea from outside *must* be had. It is satisfactory to learn from the latest authority on Russian affairs,—the Hon. George M. Curzon, M. P.,—that, instead of a feeling of hostility to England as was supposed to exist, there is rather the contrary, and "the main and dominating feeling is an abiding and overpowering dislike of Germany." When Mahomet could not get the mountain to come to him, he went to it, and the plan which we advocate for getting at the Russian buyers is the old one,—if they will not, on our mere invitation, come to Colombo, we must just go to them! We do not forget what the Russian Consul and Agent for the Volunteer Fleet at Colombo has already done by distributing samples of Ceylon teas; but it is evidently necessary to get at the big buyers after a more direct fashion.

Every year regularly now, to the China tea ports the Russian experts resort to buy, and they are men who do not represent merely a single city or even a province, but in reality the whole Russian tea trade.

What we have therefore to do is to send a Ceylon representative to meet these gentlemen and bring under their direct personal notice what Ceylon can do in fine teas. This would cost very little. All that is wanted is an energetic, able young businessman of good address, who speaks French well, and has a fair knowledge of tea. He might well be accredited as the agent of the Ceylon Planters' Association,—not for trading purposes, but simply as the medium of making Ceylon teas known. He could be on the spot when the China tea market opened, and then, provided with ample samples, he could in the course of a few days do more to have the merits of Ceylon teas discussed, tested and, we trust, recognized among Russian experts, than by years of our present indirect methods.

The teas for distribution should be provided at the expense of the estates represented, in the hope of securing Russian orders later on. Nothing but the *very best* should be sent, and each packet should have its own estate name printed on it with the price at which it would be prepared to supply a similar tea. The Tea Fund could well afford to pay all the expenses of the special agent to and from Hankow or Poochow as the case might be and for the two months or so that he would be away, he might be allowed an honorarium of say R1,000 with all expenses paid. At the very outside therefore R3,000 should about be all that the scheme would cost the Tea Fund, and how otherwise, could it be possible at such a low price so effectually to advertise our teas among the chief Russian buyers and dealers? The estates which contributed samples, say 100 lb. each, would not lose much even in the case of those whose manufacture was not successful in catching the Russian taste; for if some of the others were more favoured and there sprang up a demand for Ceylon fine teas which would be shipped from Colombo to Russian ports direct, it would be felt immediately at home. The plethora of fine teas in the London market would be relieved forthwith, and this would have the effect of raising the price of our poorer qualities. At present Russia consumes only a very small quantity of our teas, much of it bought in London; whereas if we could secure her as a local buyer, there would be a considerable saving to be effected by shipping direct, and an advantage to local planters as well.

The Tea Fund is prepared to spend a good deal of money in trying to open America, and it is right that every effort should be made to secure new markets for our steadily increasing production; but there is one great difference between America and Russia. The Americans—at least in the older States—have evidently to be educated to appreciate our product, whereas the Russians already drink black teas. In both fields, we believe, that in time success will be ours, but whereas the subjects of the White Tear have only to be got at to prove allies—the majority of our American brethren unfortunately have to be humoured and coaxed. The China market usually opens at the end of April or the beginning of May, so that if any thing is to be done this year in this important matter, it will have to be done *at once*.

In conclusion we may be permitted to say that the scheme we have advocated, and which we consider to be a very promising one, is the idea of Dr. Duke, a gentleman who some time ago was one of the first to point out how America might be reached, and, who again shows his brother planters the way of speedily, cheaply and effectually reaching the very important Russian buyers. We feel sure that thanks will be due to him for the result, if the Tea Fund Committee take up the proposal heartily and take care to secure the right descrip-

tion of agent to work among the Russian experts. One objection offered to us by a Colombo expert to whom we mentioned the matter today, is the very large quantity of any one suitable sample of tea which a Russian buyer would probably want at once to have; but this difficulty, every season now should enable us more easily to overcome; and it is quite possible that if the Russian buyers came to know about the Ceylon trade and market being open all the year round, they would prefer smaller supplies at intervals of fresh teas, rather than the present fashion of buying a whole year's supply all at once in the China ports.

COFFEE FROM BRAZIL.

Total clearances of coffee from Rio during the last 10 years in bags of 60 kilos.

—Rio News.

[Readers will not forget, of course, that the shipments from Santos have rapidly increased of late years, un-til now they are not far behind those from Rio.—Ed. T. A.]

TOBACCO CULTURE IN SUMATRA:

UNITED LANKAT PLANTATIONS Co.

The first annual general meeting of the United Lankat Plantations Company (Limited), was held on the 4th inst., at Winchester House, Mr. David Brown in the chair.

The Chairman: I regret that the profits, though they may be considered large, are not up to the standard we expected. The loss, however, does not fall upon us. At the same time it is necessary I should explain to you the reason of this loss and the steps we have taken to prevent a recurrence of such a thing again, for I can assure you it is quite within our power. The first, but not the least important, is the change in the demand of the description of tobacco that is required by the Amsterdam dealers. In former years they used to cry out for a very strong brown tobacco. Now that is entirely changed. The whole demand now for cigars is for a green nature, and the coverings have to be of a very light and very fine description. The second point is the question of land. I have no doubt it will surprise you—especially any of you interested in English farming—to hear that the complaint is not that our land is too poor, but that it is too rich. I have a letter from our administrator who blames the land by saying that we are unable to plant the same seed for many years. It grows to such a wonderful extent that it becomes of a coarse and much too dark a description, and therefore the only way we can meet this is simply by a question of seed, and upon seed really rests the whole of this question. Unfortunately the manager who is in charge of the Tjermin estate had neglected this point, and had allowed the seed to be continued on for a third year instead of having new seed from a lighter soil. We have also made arrangements with him for taking a more careful supervision of the Tjermin estate. In 1886 the estate gave a larger profit than the Brahrang estate, which has now given us the very handsome profit this year of £30,000. I now come to the prospects of the '88-9 crop, which is now in the sheds. The prospects are very favourable. Generally throughout Sumatra the season has not been a particularly favourable one. On our estates fortunately, we are able to report that our crop is larger than it was last year, and I trust that although there is a good deal of broken leaf, it will realise good prices.

The demand in Amsterdam is, from the reports of our agents there, still very strong. America took 48,000 out of the 180,000 sold in Amsterdam last year, and it is reported that for the first sale this year, which will be in the early part of next month, American buyers, are coming over to be large purchasers again, so that our prospects of the 88-9 crop will be favourable. We have a large load from the Brahrang estate, and as that has given good prices in 1889, we look for a continuance of the same thing in 1890. The next question is as to the next year's crop. The administrator writes:—"Men are all on the fields, with the exception of forty." Besides the decreased expense, in the engagement of coolies the re-engagement testifies, to an extent you can hardly imagine, to the good working of the place, and testifies also to the fact that the coolies, who are interested in the cultivation and are paid according to the amount of tobacco they return, are satisfied they have really a good thing. We have made arrangements to increase the cultivation on each estate of 100 fields, and with this increased cultivation the expenses should proportionally decrease. I propose that the report be adopted, and that a dividend at the rate of 5s. be paid.

Mr. Jones seconded the motion.

In reply to questions, the Chairman said the question of the purchase of the Ashahan estate had perhaps better be left in abeyance. He thought it should not be treated too publicly. The land was very valuable, and they had received reports to the effect that the tobacco grown on the Ashahan estate was very good, and he might mention that the average rate for Ashahan tobacco last year was as high as for Lankat tobacco. The dividends would probably be paid half-yearly. The crop last year was very much delayed. This year it was a much earlier crop, and it depended on their ability to work off the crop whether they would pay a half-yearly dividend. The managers were paid a fixed sum—a small sum and the total of their payment for salary depended on the receipts of the work. This system had always from the very first been adopted in Sumatra. It was a most excellent system, and ran through the whole of the working of the estate. The coolies and labourers were paid by result, and the manager and assistant-manager were paid a certain portion by result. Upon the Brahrang estate the managers' commission amounted to £4,000, whereas upon the Tjermin estate they received almost nothing. It took two years to realise their crop, and when they were planting the crop they were not aware of the actual description of tobacco that would be on demand when it came to market. Good tobaccos of all descriptions in Amsterdam would realise a very handsome profit, and, looking at the demand which still existed, he could assure them he had never known a season in which the prospects of tobacco-planters were better, so long as their land was good and of even quality, and properly and efficiently managed.

The motion for the adoption of the report was then put and carried.

Mr. Drought: There is one fact in connection with the report that our chairman could not very well touch upon. The fact to which I refer is the relinquishing by the vendor company of its share, under agreement, of the 1889 profits. As stated in the prospectus, I was signatory of the second part to the agreement between the old and the new company, and acting in such capacity, as soon as I found the crop on Tjermin was certain to be disappointing, I wrote to the liquidator of the old company, under the date November 19th last, requesting that the group of vendors comprising the old company would take into consideration the relinquishing of the agreed amount of profit of the 1889 crop in favour of the shareholders in this company. The vendor company was entitled to the sum of £16,000 out of the 1889 profits under the agreement I have mentioned, and this sum, less a trifling amount, was at once allocated without demur to the shareholders in this company. I beg, gentlemen, to move the following resolution:—"That a most cordial vote of thanks be tendered to the few gentlemen who comprised the members of the old

Lankat Plantations Company for their liberal behaviour in this matter, and that this meeting expresses its keen appreciation of their conduct."

Mr. Peachey seconded the motion, which was carried unanimously.—*L. and C. Express*, Feb. 7th.

PLANTING IN NETHERLANDS INDIA: COFFEE AND COOLIES.

(From the *Straits Times*, Feb. 25th.)

The Surabaya *Courant* notes the fact that distress has taken firm hold of the natives in East Java owing to short crops. The people cannot find a livelihood in most cases as estate labourers, owing to Government obstruction. The law interferes so vexatiously between planters and coolies that, on many estates, the crops cannot be gathered in time for want of hands. On some plantations, for instance, hundreds of piculs of coffee had to remain unplucked and untouched in consequence.

This year's coffee crop in East Java, so says the *Locomotief*, presents every appearance of being a short one, owing to leaf disease and bad weather.

The Governor-General has given permission to one G. A. Brend to recruit 500 natives in Netherlands India for coolie labour in Australian sugar plantations, on condition of his giving due security for fair dealing and for their safe return to that island free of cost.

In West Java, a planter named Munder has fallen victim to the murderous grudge of a Chinese mandor on his cinchona plantation. The *Locomotief* ascribes the murder to revenge on the part of the Chinaman whom Mr. Munder had discharged.

RUBBER CULTIVATION IN CEYLON.

Mr. J. A. Betts, Assoc. M. Inst. C. E., a representative of the Indiarubber, Gutta Percha and Telegraph Works Co., Ltd., Calcutta, is down here on a health trip, having had a bad attack of fever, in addition to which he has also a sprained ankle. He is stopping at the Galle Face Hotel, but hopes to return to Calcutta in a few days. While in our office this morning he spoke about the cultivation of rubber, and said he had been talking to Mr. Bois, of Messrs. J. M. Robertson & Co., who told him he was just sending home some samples of Ceylon rubber, but did not think they would be up to much. It is inferior to the Darjeeling rubber, which, in its turn, is inferior to the Brazil article. In Darjeeling the tree has not hitherto been cultivated, but lately Government have been planting it a good deal with Brazil seed. Brazil sends the largest quantity to the home market, and the Indian exports have lately been considerable, but the supply is not yet equal to the demand. The principal objection to the cultivation of rubber is the fact that a man's money is "tied up" in it so long before he gets any return—ten years at the least. Even this is too soon to tap the trees: they ought to be left till they are at least 20 years old, and then they can be tapped every year. Mr. Betts thinks, however, that rubber trees might perhaps be planted for shade on tea estates. He will find a heap of information in our compilation "All about Rubber." It is a pity he should not see some of the old trees in Dumbara and Matale.

NOTES ON PRODUCE AND FINANCE.

A grocer, writing to a contemporary upon the subject of a possible reduction in the tea duty, says:—"The first question which forces itself on one's mind is, 'Do the public—the consumers—want tea cheaper than it is now?' I do not recollect having seen or heard of any one consumer of tea clamouring either at a public meeting or through the medium of the Press for the abolition of the duty. Is there a single grocer's shop in the whole country in which the exclamation, 'Tea and sugar are cheap enough,' has not

been repeatedly uttered even by the poorest people in times of depression? Your readers can testify to this. Again, it may be asked, Do the grocers, or teadalers themselves want it? To this I unhesitatingly reply, No! Many grocers, indeed, would regard a 6d per pound reduction in the price of tea as little short of a calamity to the trade. In the interest of equitable taxation, too, it is only fair that the most popular of all non-alcoholic beverages should bear, at least, some portion of the country's burden; more especially when it can be landed on our shores at a price never dreamed of when last the duty was reduced. Once more one may ask, Are the working classes of this country owing to the present price of tea, debarred from drinking as much as they wish, or would they be likely to indulge in that beverage to any greater extent than they do now if the duty were taken off? To these queries I answer, No." This correspondent seems so intimately acquainted with the desires of his fellow creatures that he leaves nothing more to be said on the subject.

In America the manufacture in large quantities of a spurious coffee berry has been discovered, made of flour and water and coloured to closely resemble the real article, so that even experts have been deceived. In taste, of course, the counterfeit is easily detected; but, nevertheless, large quantities have been sold in the Eastern States. The sham berry is mixed with the genuine berry. This ingenious fraud originated in London, whence the American coffee importers say it was at first imported.—*Home and Colonial Mail*, Feb. 4th.

GEMS AND GOLD IN THE NEIGHBOURHOOD OF COLOMBO.

"In the mountains around Adam's Peak"—says a very old writer on Ceylon—"they collect 'precious stones of every description, and in the 'Valleys they find those diamonds by means of which they engrave the setting of stones on 'rings.' The region of Sabaragamuwa at the foot of the Peak has ever had the pre-eminence in our island history as the land of gems and although rich 'finds' have been made at widely separated spots in the Central, Southern and Western-maritime districts; yet gem-digging as an industry has ever been associated with the region around and south of Ratnapura, 'the city of gems.' The case is different with gold. The plutonic rocks of the Central Province though in many places very attractive to the seeker of auriferous quartz, have never proved otherwise than slightly metaliferous. But in the rivers flowing to the coast, and especially to the Western coast, gold has always been found in minute particles—so that the old story is as true of Ceylon as it is of India, that when natives residing near rivers have nothing better to do they go and wash for gold and they make sometimes as much as 'two fanams a day,' while it is on record that a man once made as much as 'four fanams!' This is calculated to impress the stranger who asks eagerly, it may be, the value of a 'fanam,' but who collapses on learning that it is but the sixteenth of a rupee! It has however been pointed out again and again that the gold found so freely in minute specks in the Mahaoya, and others of our rivers, must have its matrix in the region higher up. Mr. Blackett of Dolosbage did as much perhaps as any pioneer to endeavour to come on this matrix and the result from a tunnel he bored into a quartz reef on his property, was tested in the Assay Office, Victoria, and gave a yield of gold per ton which though it might justify working where all the appliances were at hand, would scarcely satisfy capitalists to begin in a new country. It is Mr. Blackett's firm opinion however that much better results

could be got on his Dolosbage reef by going deeper; but with his tea flourishing so well aboveground, he does not care, at least for the present, to carry his mining operations farther.

We mention this merely *en passant*; for we have to do today with both Gold and Gem Digging at our very doors not on an extensive scale as yet; but still sufficiently so to create an interest in industries which have hitherto been confined to interior districts. The intelligence of a Gemming industry within a few miles of Colombo reached us through Mr. L. Siedle who is well-known as one of the best judges and largest dealers in local precious stones. A few days ago Mr. Siedle was surprised at a quantity of "stuff," including some good gems, being laid before him got from a pit on the other side of the Kelani river and only a few miles from Colombo. He made enquiries and found that washing for gold had succeeded digging for gems and that with the results of both operations, the people concerned, expressed themselves as satisfied. We had the pleasure this forenoon of accompanying Mr. Siedle to the spot, the drive after passing the Bridge of Boats being along the old Kandy road for a mile and then for a couple of miles or more on a minor road which crossing the railway and passing through the village of Waragoda, runs parallel to, but about a mile away from the Kelani river at the point where the scene of the Gem and Gold operations is reached. This is in the garden of a respectable Moorman who owns about 8 acres of fully planted land with coconut and fruit trees. At one corner, he wanted to sink a well, and it was in so doing that he came on a stratum which led him to think of gems and eventually led to the discovery of a layer of the much-prized "illan" from which a considerable harvest of valuable stones had been gathered. In sinking the pit for gems, the Moorman took into partnership an intelligent well-to-do Sinhalese who had gained experience of gemming and the value of stones in Rakwana. Then for the workmen, there were not only Sinhalese employed, but some Coast Moormen whose business in life it is to wash for gold. Fine, tall, wiry men, the three or four of this class on the spot were, with eyes as keen as a hawk's for anything precious and in great contrast with the ample rotund form of their brother-eligionist, the gentleman of the garden! The gempit is now filled with water and operations are for a time suspended, so that we were unable to judge exactly of the extent of the operations. But we saw no reason to doubt the statement that after digging down some 18 to 24* feet to the "illan," they had tunnelled in following the layer a considerable distance on three sides of their pit, and then, (there being no regular gempit diggers among their number,) they were afraid to go on when the rains began to fill the place or to try pumping out; but rather preferred a little later to sink another shaft. In Mr. Siedle's opinion, the first pit sunk was ridiculously too wide, almost double what regular diggers in Rakwana would have made it. The formation was very clayey and a good deal of potters' clay is got in the neighbourhood. A large heap of rounded pebbles mingled with promising pieces of white quartz testified to part of the detritus taken out, while close by lay a mass of reddish clay with traces of limestone which was come upon below the "illan" and which induced the workmen not to go deeper. Mr. Siedle thinks this was a mistake, and that very probably below this stuff there may be further gem deposits

while digging should go on until the bed rock is reached. More interesting than the pebbles and clay were bags full of gemiferous "refuse" which, although all the really valuable stones had been washed out, still contained interesting pieces of tourmaline, sapphire, pale rubies, garnets, crystals, amethysts &c. We were interested in the long sloping wooden trough employed for washing the "illan" with divisions of iron gratings at intervals by which first the largest, then smaller and smaller stones were intercepted and retained. Of course all the washing in this trough was done by hand under inspection; but as the men employed were remunerated by having shares in the business—the digging being carried on as a joint-stock concern—there was less temptation to appropriate any of the findings. The garden proprietor was very particular that with all the digging, sluicing and washing as few of his young coconut trees as possible should be interfered with, the sites for shafts being chosen in the centre of the squares. To finish about the gems, we may mention that on our way back, calling at the residence of the Sinhalese partner we saw a considerable portion of the gem harvest from this pit and the connected tunnels. There were parcels of sapphires and rubies—but both distinctly inferior—while on the other hand that of catseyes contained some promising material. Already a good deal of the "findings" had been sold and the work though more expensively done than was necessary, has been profitable enough to encourage further operations. Now there is no reason so far as can be judged why a considerable extent of land in the neighbourhood should not have the same gemiferous stratum or strata at certain depths. The Sinhalese it seems, explore with a primitive borer consisting of a wooden rod with steel head and point, which when it enters the gem-yielding stratum grates on the sharp pieces of quartz corundum, &c. and so gives a fair indication to the operator. But clearly this cannot be used for any great depth. There are gardens on each side of the Moorman's which seem quite as likely to be profitable locations for gempits as his, and it is quite possible that we have been looking at what may be the beginning of a considerable industry.

As regards gold, some of the Coast Moormen were so struck with some of the "stuff" brought out of the gempits—titaniferous black sand in connection with the gravel and clay—that when the heavy rains put a stop to their gemming work they set to, and washed for gold. Their arrangement for this purpose is of the simplest: an oblong wooden spout shut at one end, open at the other made of hard smooth wood, and placed at such an angle in front of the squatting Moorman as ensure, ordinary sand or clay running off with the rush of water poured on, while the black sand and much more the specks of gold remained behind. One man shovelled some of the sand-clay heap into the "sluice," the operator dipped his scoop made of talipot leaf into the pool of water at his side and washed the stuff down the spout, working it with his left hand, and having one or two pieces of tile at the opening to keep in the layer of black sand. When a sufficient quantity had been passed through in this way to make a goodly deposit of the black sand in the trough or sluice, the Moorman began to work it carefully, so that the lighter portions only were cleared away: he then got clean (not the yellow clayey) water poured on through which the specks of gold became clearly visible and then an earthen chatty at the end of the spout caught the last portion of the heavy sand washed down with the gold. Each washing in this way took about half-an-hour and

* 18 feet the top layer of illan: 24 feet the bottom cached.

when the day's work is done, the chatty is brought to the principal Moorman who alone has the quicksilver, a few globules of which dropped into the chatty, quickly separates the gold. This work like the gemming is carried on on joint-stock principles. We saw a small ball of gold, the result of melting two days' washings and which was worth over a sovereign. No great fortune therefore so far in washing out say ten rupees worth of gold daily; but as the work is done by a man and a boy, those concerned no doubt consider the profit to be sufficient. Some distance away it was reported to us that a European is engaged in washing for gold with a number of natives and that he is employing steam pumping machinery and doing well—that is getting £2 worth of gold a day—but this story has to be verified. Save as an interesting adjunct to the gem-digging, there is nothing attractive in the gold-washing at Waragoda, except as showing how freely and widely gold in minute particles is distributed in Ceylon. The chance of finding a good deposit of gems, on the other hand, is much more likely to attract native industry, capitalists and possibly, eventually European means of working. We do not suppose that the Kelani Valley gemiferous deposit will ever prove so rich as the deposits found in Rakwana; but as a supplementary industry to the latter, it is well worthy of the attention of the experts now in the island, and of all interested in the development of the mineral wealth of Ceylon.

PAYING DUTY ON TEA ON LANDING.

Our readers' attention was recently drawn to this subject by our correspondents Messrs. William Walker & Sons, a firm of high standing and well-known in Aberdeen and Scotland generally, who have sent a petition to the Chancellor of the Exchequer, urging him to separate the tea received into England, and place that required for exportation in a bonded warehouse, while the duty on that intended for home consumption should be paid at the ship's side. This in theory seems reasonable enough, but in practice it would not be found workable from the simple fact that when tea is imported it is impossible in nearly every instance to say whether it will be ultimately used in this country or exported. Then, with regard to the payment of the duty in a lump sum instead of instalments, when the tea is actually required for consumption, objections would be raised to this change—first by the importers, who would be called upon to advance the whole of the duty upon the arrival of the steamer conveying the tea, and before they had an opportunity of selling it. Even supposing the amount of the duty were reduced from sixpence to (say) three or four pence per pound, it would involve the importers in a considerable outlay, which would have to be paid in cash, and would probably lead to a restriction in the term of the prompt. Considering how unprofitably the China tea trade has been carried on for the last few years, it is hardly likely the suggestion would meet with favour at the hands of the importers.

Secondly, the retail grocers would, in addition to having to bear the loss of time in the prompt to which we have already alluded, have also to pay the amount of the tea duty on all they might require to buy, whether required for immediate use or for keeping in stock. Now it is well known that certain kinds of tea are only imported at particular times of the year, and grocers, in order to maintain the quality of their blends of tea, are compelled to buy in advance of their wants, and it would be hard to make them pay the duty on the whole of the purchase at the prompt. The privilege of storing tea in bond being one that has been enjoyed for so many years, and has never involved the Crown in the loss of a single sixpence, some strong reasons must be assigned before any change in the mode of collection should be entertained.

The convenience which would attend the fact of tea being free and stored in warehouses, where the delivery could take place without the vexatious delays which now occur, is, of course, a point no one will be inclined to deny, and moreover, the sampling question would, no doubt, be placed on a more satisfactory footing—a consummation devoutly to be wished; but the primary difficulty of paying the duty in advance has to be got over first, and, without going so far as to say that the remedy would be as bad as the disease, yet we are sure the opposition to the course proposed by our correspondents would be very great, and, as far as we can learn, the trade generally—and certainly the retail grocers—have not shown any evidence of their appreciation of the suggestion to put their money in the hands of the Crown before they are absolutely obliged to do so. The profits on grocery articles in the present day do not allow of any gratuitous offerings to the Chancellor of the Exchequer, but, on the other hand, every penny has to be saved and expenses curtailed as far as possible to enable grocers to make a living in this age of excessive competition and low prices.—*Grocer*, Feb. 8th.

FORESTS AND FORESTRY.

Yesterday afternoon a paper on "The Utility of Forests and the Study of Forestry" was read by Dr. W. Schlich (Professor of Forestry at the Royal College of Engineering, Coopers-hill) before the Indian section of the Society of Arts. The chair was taken by Major-General Michael, C.S.I., and among those present were Sir Peter Lumsden, Sir Owen Burne, Sir George Birdwood, Sir Henry Cunningham, Sir Alexander Taylor, Sir Juland Danvers, Sir J. Fayerer, Sir Charles Bernard, General Keatinge, Mr. Seton-Karr, Dr. Hyde Clarke, and Mr. T. H. Thornton.

Dr. SCHLICH, in the course of his paper, said that although forestry had been practised in the United Kingdom for centuries, it did not receive much attention until the progress of forestry in India required the appointment of properly qualified experts who could not be procured in this country. In 1864 Dr. D. Brandis (now Sir Dietrich Brandis, K.C.S.I.) had been appointed the First Inspector-General of Forests to the Government of India, and that eminent organizer perceived at once that if forestry in India was to be really successful and lasting it was necessary to secure the service of an efficient staff to manage the extensive forests of our Indian Empire. As to the importance of forests there could of course be no doubt whatever, and although, observations in India had not yet taken place over a sufficiently long period, to yield decided results, those in Germany, France, and Switzerland had settled many questions, while they had thrown additional light on others. As far as our knowledge went at present, the following summary indicated generally the utility of forests in the economy of man and of nature:—(1) Forests supply timber, fuel, and other forest produce; (2) they offer a convenient opportunity for the investment of capital and for enterprise; (3) they produce a demand for labour in their management and working, as well as in a variety of industries which depend upon forests for their raw material; (4) they reduce the temperature of the air and soil to a moderate extent, and render the climate more equable; (5) they increase the relative humidity of the air, and reduce evaporation to a considerable extent; (6) they tend to increase the rainfall;* (7) they help to regulate the water supply, insure a more sustained feeding of springs, tend to reduce violent sludge, and render the flow of water in rivers more continuous; (8) they assist in preventing landslips, avalanches, the silting up of rivers and low lands, and arrest moving sands; (9) they reduce the velocity of air currents, protect adjoining fields against cold or dry winds, and afford shelter to cattle, game, and useful birds; (10) they assist in the production

* On absolute rainfall the effect is very slight. Their great use climatically is in conserving moisture, —ED. T.A.

of oxygen and ozone; (11) they may, under certain conditions, improve the healthiness of a country, and under others endanger it; (12) they increase the artistic beauty of a country. The importance of employing really competent men in the management of forest estates, whether belonging to the State or to private owners, had led to the establishment of forest schools in most European countries. There were nine such schools in Germany alone, some forming parts of Universities, others being attached to higher technical schools, and some being independent institutions. Most of these were first-class schools where instruction was given by a considerable number of professors. In this country there were two places where scientific forestry could be studied. One was at the University of Edinburgh under Dr. Somerville, and the other at Coopers-hill. The instruction in forestry at the latter institution was, up to the present date, given by the reader of the paper, and it was now contemplated to engage a second professor of forestry and to double the amount of instruction hitherto given. In addition to the instruction given at the college practical instruction was given in the adjoining Windsor Forests, and visits to more distant forests in England and Scotland were also made. At the completion of the course at the college the students who had qualified in the various branches of study proceeded to the Continent, where they were taken charge of by Sir Dietrich Brandis, who, during a period of not less than three months, took them to a number of the most interesting forest districts in Germany, Switzerland, and Austria, where they studied the management of forests which had been under systematic treatment for a long period. This brought their instruction to a close, and the young men then proceeded to India to take their places in the forest department of that country. Thus it would be seen that there was in England the nucleus of an institution which only awaited the full support of the colonies and of the mother country to develop into an institution worthy of the best forest schools of the Continent.

In the discussion which followed the reading of the paper, Sir C. Bernard, Mr. Baden-Powell, Sir Joseph Fayer and other gentlemen took part.

The CHAIRMAN said that no one who had visited the great forest regions of Germany, Austria and France could fail to be impressed with the visible effects of good management, and wish they were more generally apparent in England and Scotland. There were signs, however, that the education and practical training of foresters was becoming more thought of at the present time in England, and he ventured to predict that Dr. Schlich would shortly have a good many students under him who were destined for home employment and not for India only. Personally he knew more about the value of forestry and the life of a forester in India having spent 7 or 8 of the happiest and perhaps the most useful years of his youth as a forest officer; that was more than 40 years ago, before the time arrived for experts like Dr. Schlich and his distinguished predecessor Sir Dietrich Brandis to come to the country. He could therefore tell any of Dr. Schlich's students who might be present that the life of a forester in India was not only a career of importance, but that it was one full of interest and of real enjoyment. The formation of the department in which they would serve—and in which Dr. Schlich served so well and successfully—had justly been characterized by Sir Richard Temple as one of the greatest achievements effected in India during the reign of her Majesty the Queen.

The proceedings terminated with votes of thanks to Dr. Schlich and the chairman.—*London Times*.

Mr. E. THURSTON, the Superintendent of the Government Central Museum, leaves Madras in a few days for Ootacamund, to collect specimens of birds and insects to be met with on the Nilgiris. He will be accompanied by a Collector and a taxidermist.—*M. Mail*, Feb. 14th;

MANUFACTURES AND INDUSTRIES IN WESTERN INDIA.—Eighty-one factories to which Act XV of 1881 has been applied existed in the island of Bombay and were visited by the Inspector during the year 1888-89. Children under twelve worked in six mills: the manager of one of which was prosecuted and punished for employing them as full time hands. The number of accidents reported during the year was 445, only six of which, however, had fatal results. The number of steam boilers examined under Act III of 1887 was 494 or 140 more than in the previous year. The receipts of the department exceeded the expenditure, and the deficit of the previous year was replaced by a fair surplus.—*Indian Agriculturist*, Feb. 8th.

LEAF DISEASE AND COFFEE.—Mr. Turing Mackenzie writes sensibly and to the point, in his letter to a Singapore paper. Of course we all in Ceylon recognised the conversion of our hill country into one product of cultivation as the primary cause of the pest; but once having appeared and that first in a remote, by no means crowded district, the fungus went everywhere, and in Travancore and Wynaad at least there were isolated estates devastated by it. In Ceylon too, it must be remembered, that the small and widely separated patches of coffee around native huts, growing amidst jak, coconut, areka and other trees, suffered equally with the widest expanses on estates.

CORAL; PUMPKING; SHARK OIL.—When at various points along the coast South of Colombo depôts are formed of coral to be burnt in limekilns and turned into chunam for building purposes, or to be sold to planters for manure. These supplies of coral are brought round from our southern shores—near Matara especially—by dhonies which also occasionally add to their cargo, vegetables such as enormous pumpkins &c. The other morning near Dehiwala we found a large number of kerosine cases containing tins of oil being taken ashore from one of these dhonies as well as the usual coral cargo and big vegetables for the Colombo market. On enquiry and examination, it turned out that the tins contained not kerosine, but shark fish oil, prepared on the Matara coast and sent round to be disposed of at Colombo where there is a good demand it seems, for such purposes as cleaning leather, harness, &c.

THE DEHRA DUN TEA COMPANY LIMITED.—The general meeting will be held at Dehra on the 28th instant. For the year ending 31st December 1889 the expenditure was R99,163, and it is stated that the items of expenditure taken separately, with the exception of interest and establishment, compare favourably with those of 1888. The interest account exceeds the estimate, due partly to the delay in disposing of the spring crop teas sent to America and Canada. The outturn of tea for 1889 was 439,578 lb. or 9,578 lb. more than was estimated. Of the crop 46,000 lb. were sent to New York and Toronto. The company's teas did not obtain remunerative rates at New York, but at Toronto they seem to be in better demand. The divisible balance, after estimating the value of the tea unsold, is R40,197, out of which the directors recommend the payment of a dividend of 4½ per cent, which will absorb R39,510. As the shares are at present quoted at 45, the dividend of 4½ per cent represents a very good rate of interest to anyone who buys into the company at current price. The Dehra Dun Tea Company has paid a steady dividend, varying from 4 to 5 per cent for some years past. The average dividend for the last five years is 4.6 per cent, so at the present price the shares seem worth the attention of investors.—*Pioneer*, Feb. 25th.

HOW RAIN IS FORMED.*

In certain villages in the Indian Central Provinces, besides the village blacksmith, the village accountant, the village watchman, and the like, there is an official termed the *gopogari*, whose duty it is to make rain. So long as the seasons are good and the rain comes in due season, his office is no doubt a pleasant and lucrative one. It is not very laborious, and it is obviously the interest of all to keep him in good humour. But if, as sometimes happens, the hot dry weather April and May is prolonged through June and July, and week after week the *ryot* sees his young sprouting crops withering beneath the pitiless hot winds, public feeling is want to be roused against the peccant rain-maker, and he is led forth and periodically beaten until he mends his ways and brings down the much-needed showers.

You will hardly expect me, and I certainly cannot pretend to impart to you the trade-secrets of the professional rain-maker. Like some other branches of occult knowledge which Madam Blavatsky assures us are indigenous to India, this art of rain-making is perhaps not to be acquired by those who have been trained in European ideas; but we can at least watch and interrogate Nature, and learn something of her method of achieving the same end; and if her scale of operations is too large for our successful imitation, we shall find that not only is there much in it that may well challenge our interest, but it may enable us to some extent to exercise prevision of its results.

Stated in the most general terms, Nature's process of rain-making is extremely simple. We have its analogue in the working of the common still. First, we have steam or water vapour produced by heating and evaporating the water in the boiler; then the transfer of this vapour to a cooler; and finally we have it condensed by cooling, and reconverted into water. Heat is communicated to the water to convert it into vapour, and when that heat is withdrawn from it, the vapour returns to its original liquid state. Nature performs exactly the same process.

In the still, the water is heated until it boils; but this is not essential, for evaporation may take place at all temperatures, even from ice. A common little piece of apparatus, often to be seen in the window of the philosophical instrument maker, and known as Wollaston's cryophorus, is a still that works without any fire. It consists of a large glass tube with a bulb at each end, one of which is partly filled with water; and, all the air having been driven out of the tube by boiling the water, it is hermetically sealed and allowed to cool. It then contains nothing but water and water vapour, the greater part of which recondenses when it cools. Now, when thus cold, if the empty bulb be surrounded by ice, or, better, a mixture of ice and salt, the water slowly distils over, and is condensed in the colder bulb, and this without any heat being applied to that which originally contained the water. And this shows us that all that is necessary to distillation is that the condenser be kept cooler than the evaporator.

Nevertheless, at whatever temperature it evaporates, water requires heat, and a large quantity of heat, merely to convert it into vapour; and this is the case with the cryophorus, for if the evaporating bulb be wrapped round with flannel, and so protected from sources of heat around, the water cools down until it freezes. That is to say, it gives up its own heat to form vapour. A simple experiment that anyone may try with a common thermometer affords another illustration of the same fact. If a thermometer bulb be covered with a piece of muslin, and dipped into water that has been standing long enough to have the same temperature as the air, it gives the same reading in the water as in the air. But if when thus wetted it be lifted out and exposed to the air, it begins to sink at once, owing to the evaporation of the water from the wet surface, and it sinks the lower the faster it dries. In India, when a hot wind is blowing, the wet bulb sometimes sinks 40° below the temperature of the air.

* A Lecture delivered by H. F. Blanford, F.R.S., at the Hythe School of Musketry.

Now this is a very important fact in connection with the formation of rain, because it is owing to the fact that water vapour has absorbed a large quantity of heat—which is not sensible as heat, but must be taken away from it before it can be condensed and return to the liquid state—that vapour can be transported as such by the winds for thousands of miles, to be condensed as rain at some distant part of the earth's surface.

I have said that the quantity of absorbed heat is very large. It varies with the temperature of the water that is evaporating, and is the greater the lower that temperature. From water that is on the point of freezing it is such that one grain of water absorbs in evaporating as much heat as would raise nearly 5½ grains from the freezing to the boiling point. This is called the latent heat of water vapour. As I have said, it is quite insensible. The vapour is no warmer than the water that produced it, and this enormous quantity of heat has been employed simply in pulling the molecules of water asunder and setting them free in the form of vapour, which is merely water in the state of gas. All liquids absorb latent heat when they evaporate, but no other known liquid requires so much as water.

Many things familiar in everyone's experience find their explanation in this absorption of latent heat. For instance, we feel colder with a wet skin than with a dry one, and wet clothes are a fruitful source of chills when the body is in repose; although, so long as it is in active exercise and producing a large amount of heat, since the evaporation only carries off the excess, no ill consequence may ensue. Again, if a kettle be filled with ice-cold water and put on a gas stove, suppose it takes ten minutes to bring it to boil. In that ten minutes the water has absorbed as much heat as raises it from 32° to 212°, an increase of 180°. Now if it be left boiling, the gas-flame being kept up at the same intensity, we may assume that in every succeeding ten minutes the same quantity of heat is being absorbed by the water. But it gets no hotter: it gradually boils away. And it takes nearly an hour, or much than five times as long as it took to heat it, before the whole of the water has boiled away, since all this heat has been used up in converting it into steam. It was by an experiment of this kind that Dr. Black, in the last century discovered the fact of latent heat, and determined its amount; and it was the knowledge of this fact that led James Watt to his first great improvement in the steam-engine.

One more example I may give, which those who have been in India will be able to appreciate, and which those who intend to go there may some day find useful to know. Nothing is more grateful in hot dry weather than a drink of cold water. Now ice is not always to be had, but when a hot wind is blowing, nothing is easier than to get cold water, if you have a pot or bottle of unglazed earthenware, such as are to be had in every bazaar, or, what is better, a leather water-bottle, called a *chhagal*, or a water-skin. All these allow the water to soak through and keep the outside wet; and if any one of them be filled with water and hung up in a hot wind, in the course of half an hour or an hour, the evaporation from the outside will have taken away so much heat that the contents may be cooled 20° or 30°, notwithstanding that the thermometer may stand at 110° or 115° in the shade. Soda-water may be cooled in the same way if wrapped in straw and kept well wetted while exposed to the wind. But it is of little use to do as I have seen natives do sometimes, viz., put the bottles into a tub of water in a closed room. It is the evaporation that carries off the heat, otherwise the water is no cooler than the air around.

Now to return to our subject. The atmosphere always contains some vapour which the winds have taken up from the ocean, lakes, rivers, and even from land, for there are but few regions so dry and devoid of vegetation that there is no moisture to evaporate. The quantity of water thus evaporated from large water surfaces is a question of some importance to engineers, who have to take account of the loss from reservoirs, and irrigation tanks, and a good deal of attention has been given to measure the amount

lost by evaporation. In England it has been found to vary in different years from 17 to 27 inches in the year, or say from $1\frac{1}{2}$ to $2\frac{1}{4}$ inches per month on an average. Now, since in the east of England the rainfall is only about 24 inches in the year, it follows that in that part of the kingdom the loss by evaporation from a water surface is not very much less than the rain falling directly on the surface.

In dry countries the evaporation may exceed the local rainfall. In the tropics it has been found to average from $3\frac{1}{2}$ to 6 inches per month in the dry season. In the case of a large tank at Nagpur, constructed to supply the city with water, it was found that the loss by evaporation, in the hottest and driest weather was two and a half times as great as the quantity supplied for consumption.

These statistics will give some idea of the enormous evaporation that goes on from the water surfaces of the globe, and to this must be added all that takes place from the land. In the case of light showers, nearly the whole of the rain is re-evaporated; and probably, on an average, half of the total rainfall on the land is thus lost sooner or later, leaving not more than half for the supply of springs and rivers.

The quantity of vapour in the air is very variable. To us, in England, the west and south-west winds are the dampest, coming direct from the Atlantic, and north-east winds are the driest. The cause of their extreme dryness I shall endeavour to explain presently. It is no doubt partly due to the fact that they reach up another cause to which I shall have to advert later on.

The quantity of vapour in the air is usually ascertained by the hygrometer, the ordinary form of which is a pair of thermometers, one having the bulb wet, the other dry, and observing the depression of the wet bulb. The principle of this I have already explained. But the same thing may be ascertained more directly by passing a measured quantity of air through a light apparatus containing sulphuric acid, or some other substance that absorbs water vapour greedily, and weighing the whole before and afterwards. The increase of the second weight gives the weight of water absorbed. By such means it has been ascertained that air at 60° can contain as much as $5\frac{3}{4}$ grains of vapour in each cubic foot, and hot air at 80° can contain rather less than 11 grains in the same space. The quantity that air can hold increases therefore very rapidly with the temperature. But it is seldom that it contains this maximum amount, especially at the higher temperatures.

In order to condense any part of this vapour we must take away its latent heat. It is not sufficient merely to cool it till it reaches the temperature of condensation, but we have further to abstract $5\frac{1}{2}$ times as much heat as would raise the condensed water from the freezing to the boiling point. Before, however, proceeding to consider how this cooling is effected, the question arises, What is the condensing point? For, obviously, since water can evaporate at all temperatures, so we should expect that it may condense at all temperatures. On what, then, does the condensing point depend?

I mentioned just now that air at the temperature of 60° can contain as much as $5\frac{3}{4}$ grains of vapour, and at 80° rather less than 11 grains in each cubic foot. Obviously, then, if air at 80° , containing this maximum quantity, be cooled to 60° , it must get rid of more than 5 grains, or nearly half its vapour, and this excess must be condensed. I speak of air containing these quantities, but in point of fact it makes no appreciable difference whether air be present or not. An exhausted glass vessel of one cubic foot capacity can hold $5\frac{3}{4}$ grains of vapour at 60° and no more, and nearly 11 grains at 80° and no more; and if, when thus charged at 80° , its contents be cooled to 60° , more than 5 grains will be condensed. If, however, it contain only $5\frac{3}{4}$ grains at 80° , none will condense until the temperature falls to 60° , but any further cooling produces some condensation. Thus, then, the condensing point depends on the quantity of vapour present in the air, and is the temperature at which this quantity is the maximum possible for that temperature.

This preliminary point being explained, we may now proceed to inquire what means Nature employs to condense the vapour in the air, producing at one time dew

and hoar-frost, at another time fog and cloud, and at another rain, hail, and snow.

Let us take the case of dew and hoar-frost first, as they are comparatively simple. And in connection therewith I may relate a little incident that took place at Calcutta some years ago. A gentleman, who had not much acquaintance with physical science, was sitting one evening with a glass of iced brandy and water before him. It was in the rainy season, when the air, though warm, is very damp, and he had a large lump of ice in his tumbler. On taking it up, he noticed to his surprise that the glass was wet on the outside, and was standing in quite a little pool of water on the table. At first he thought his tumbler was cracked, but putting his finger to his tongue he found the fluid tasteless. "Very odd!" he remarked; "the water comes through the glass but the brandy doesn't."

Now, however with our present knowledge we may be inclined to smile at the simplicity of this remark it so happens that up to the end of the last century very much the same explanation was popularly held to account for dew. It was supposed to be a kind of perspiration emitted from the earth, and no satisfactory explanation of the phenomenon had been arrived at by the physical philosophers of the day. It remained for Dr. Wells to prove, by a long series of observations and experiments, which have been quoted by Sir John Herschel and Mr. John Stewart Mill as a typical instance of philosophical inquiry, that the cold surface of grass and shrubs condenses the vapour previously held in suspension in the air, these surfaces being cooler than the air, and below its point of condensation. And such of course, is also the case of the glass tumbler containing ice. Any one may try the experiment for himself. To produce hoar-frost, it is only necessary to cool the condensing surface below the freezing point, which may be done by crushing some ice and mixing it with salt. A tin pot is better than a glass to make this experiment.

When not only the ground, but also the air to a considerable height above it, is cooled in like manner, we have the production of fog, fog being the form in which the vapour is first condensed, and consisting of water in drops too minute to be separately visible. The formation of fog is very much aided if the air be laden with smoke. Smoke consists of extremely minute particles of unburnt coal or other fuel, and these cool faster than the air at night, and so cool the air in contact with them. Each one of them, too, condenses water on its surface, and being thus weighted they sink and form that dense fog that Londoners know so well.

Clouds are essentially the same as fog, but formed high up in the air. But in their case, and that of rain, snow, and hail, another and different cooling agency comes into play, and this will require some preliminary explanation.

I dare say that some of you may at some time or other have charged an air-gun. And if so, you will be aware that when so charged the reservoir becomes pretty warm. Now this heat is produced, not, as might be supposed, by the friction of the piston in charging, but is due to the fact that work has been done upon the air by compressing it into a very small space; in other words, work has been converted into heat. If the compressed air be allowed to escape at once, its heat is re-converted into work. It has to make room for itself by thrusting aside the atmosphere into which it escapes, and when thus expanded it is no warmer than before it was compressed. Indeed, not so warm, for it will already have parted with some of its heat to the metal chamber which contained it. And if when compressed it is allowed to cool down to the ordinary temperature, and then to escape, it will be cooled below that temperature just as much as it was heated by compression. Thus, if in being compressed it had been heated 100° , say from 60° to 160° , and then allowed to cool to 60° , on escaping it will be cooled 100° below 60° , or to 40° below zero, which is the temperature at which mercury freezes. This is the principle of the cold air chambers now so extensively employed

on ship-board for the transport of frozen provisions from New Zealand and Australia.

Bearing in mind, then, this fact—that air in expanding and driving aside the air into which it expands is always cooled—let us see how this applies to the case before us, the production of cloud and rain.

The volume of a given weight of air—in other words, the space it occupies—depends on the pressure to which it is subjected; the less this pressure the greater its volume. If we suppose the atmosphere divided into a number of layers superimposed on each other, the bottom layer is clearly subject to the pressure of all those that rest on it. This is equal to about 14½ pounds on every square inch of surface. Another layer, say 1,000 feet above the ground, will clearly be under a less pressure, since 1,000 feet of air are below it; and this 1,000 feet of air weighs slightly less than half a pound for every square inch of horizontal surface. At 2,000 feet the pressure will be less by nearly one pound per square inch, and so on. If, then, any mass of air begins to ascend through the atmosphere, it will be continually subject to less and less pressure as it ascends; and therefore, as we have already seen, it expands, and becomes cooler by expansion. Cooling from this cause is termed dynamic cooling. Its rate may be accurately computed from the work it has to do in expanding.

It amounts to 1° for every 183 feet of ascent if the air be dry or free from vapour, and if, as is always the case, it contains some vapour, the height will not be very much greater so long as there is no condensation. But so soon as this point is passed, and the vapour begins to condense as cloud, the latent heat set free retards the cooling, and the height through which this cloud-laden air must ascend to cool 1° is considerably greater, and varies with the temperature and pressure. When the barometer stands at 30 inches, and at the temperature of freezing, the air must rise 277 feet to lose 1°, and if the temperature is 60° nearly 400 feet.

Conversely, dry air descending through the atmosphere and becoming denser as it descends, since it is continually becoming subject to an increased pressure, is heated 1° for every 183 feet of descent; and fog and cloud-laden air at 30 inches of pressure and the freezing point will be warmed 1° in 277 feet only, or if at 60° nearly 400 feet of descent, owing to the re-evaporation of the fog or cloud and the absorption of latent heat.

Now let us see how these facts explain the formation of cloud; and first I will take the case of the common cumulus or heap cloud, which is the commonest cloud of the day-time in fine weather.

When after sunrise the air begins to be warmed, the lowest stratum of the atmosphere, which rests immediately on the ground, is warmed more rapidly than the higher strata. This is because the greater part of the sun's heat passes freely through a clear atmosphere without warming it, and is absorbed by the ground, which gives it out again to the air immediately in contact with it. So soon as the vertical decrease of temperature exceeds 1° in 183 feet, the warm air below begins to ascend, and the cooler air above to descend, and this interchange gradually extends higher and higher, the ascending air being gradually cooled by expansion, and ceasing to rise when it has fallen to the same temperature as the air around it. This ascending air is more highly charged with vapour than that which descends to replace it, since, as was mentioned before, most land surfaces furnish a large amount of moisture, which evaporates when they are heated by the sun. This process goes on until some portion of the ascending air has become cooled to the point of condensation. No sooner does it attain this, then a small tuft of cumulus cloud appears on the top of the ascending current, and the movement which was invisible before now becomes visible. In a calm atmosphere each tuft of cloud has a flat base, which marks the height at which condensation begins, but it is really only the top of an ascending column of air. No sooner is this cloud formed than the ascent becomes more rapid, because the cooling which checked

its further ascent now takes place at a much slower rate, and therefore the cloud grows rapidly.

On a summer afternoon when the air is warm and very damp, such cumulus cloud ascends sometimes to very great heights, and develops into a thunder-cloud, condensing into rain. Rain differs from fog and cloud only in the size of the water drops. In fog and cloud these are so minute that they remain suspended in the air. But as the cloud becomes denser, a number of them coalesce to form a rain-drop, which is large enough to overcome the friction of the air. It then begins to fall, and having to traverse an enormous thickness of cloud below, it grows larger and larger by taking up more and more of the cloud corpuscles, so that when finally it falls below the cloud it may have a considerable size.

Such, then, is the mode in which rain is formed in an ordinary summer shower; and the more prolonged rainfall of stormy wet weather is the result of a similar process, viz. the ascent and dynamic cooling of the moist atmosphere. But in this case the movement is on a far larger scale, being shared by the whole mass of the atmosphere. It may be, over hundreds or thousands of square miles; and to understand this movement we shall have to travel somewhat further afield, and to inquire into the general circulation of the great atmospheric currents set in movement by the sun's action in the tropics, and modified by the earth's diurnal rotation and the distribution of the continents and oceans on its surface.

Before, however, entering on this subject, which will require some preliminary explanation, and in which we shall have to take account both of ascending and descending currents on a large scale, I will draw your attention to another and simpler case, in which both these classes of movements are prominently illustrated, and in which they exhibit their characteristic features in a very striking manner.

In the valleys of the Alps, more especially those to the north of the central chain, in Switzerland and the Tyrol, there blows from time to time a strong warm dry wind, known as the Föhn. It blows down the valleys from the central chain, melting the snows on its northern face, and although there is more or less clear sky overhead, all the southern slopes of the mountains are thickly clouded, and heavy rain falls on the lower spurs and the adjacent plain, replaced by snow at the higher levels up to the passes and the crest of the range. Cloudy weather also prevails to the north in Germany, and the weather is stormy over some part of Western Europe.

It is only since the general introduction of telegraphic weather reports and the construction of daily weather charts have enabled us to take a general survey of the simultaneous movements of the atmosphere over the greater portion of Europe, that this Föhn wind has been satisfactorily explained.* It is found that when a Föhn wind blows on the north of the Alps, the barometer is low somewhere to the north or north-west, in Germany, Northern France, or the British Isles, and high to the south-east, in the direction of Greece and the Eastern Mediterranean. Under these circumstances, since the winds always blow from a place of high barometer to one of low barometer, a strong southerly wind blows across the Alps. On their southern face it is forced to ascend, and therefore, as just explained, it is cooled and gives rain in Lombardy and Venetia, and snow at higher elevations. But having reached the crest of the mountains, it descends to the northern valleys, and being by this time deprived of a large part of its vapour, it becomes warmed in its descent, owing to compression, absorbs and re-evaporates the cloud carried with it, and is then further warmed at the rate of 1° for every 183 feet of descent. Thus it reaches the lower levels as a warm dry wind, its warmth being the effect of dynamic heating.

Other mountain chains afford examples of the same phenomenon. A very striking instance, which much impressed me at the time, is one that I witnessed

* The explanation was originally given by Prof. J. Hann of Vienna.

many years ago in the mountains of Ceylon; and it was afterwards mentioned to me by Sir Samuel Baker, who had been equally struck by it. My own experience is as follows:—In June 1861, I paid a week's visit to the hill sanitarium of Newara Eliya, at an elevation of 6,200 feet, on the western face of Pedro Talle Galle, the highest mountain in the island. The south-west monsoon was blowing steadily on this face of the range; and during the whole time of my stay it rained, as far as I am aware, without an hour's intermission, and a dense canopy of cloud enveloped the hill face, and never lifted more than a few hundred feet above the little valley in which Newara Eliya is built. But on leaving the station by the eastern road that leads across the crest of the range to Badulla, at a distance of five miles one reaches the col or dip in the ridge near Hackgalle, and thence the road descends some 2,000 feet to a lower table-land which stretches away many miles to the east. No sooner is this point passed than all rain ceases and cloud disappears, and one looks down on the rolling grassy hills bathed in the sunshine of a tropical sun, and swept by the dry westerly wind that descends from the mountain ridge. In little more than a mile one passes from day-long and week-long cloud and rain to constant sunshine and a cloudless sky.

As an almost invariable rule, or at least one with few exceptions, ascending air currents are those that form cloud and rain, and descending currents are dry and bring fine weather. And this holds good whatever may be the immediate cause of these movements. We may now proceed to consider these greater examples to which I have already referred.

In the great workshop of Nature, in so far at least as concerns our earth, with but few exceptions, all movement and all change, even the movements and energies of living things, proceed either directly or indirectly from the action of the sun. Nowhere is this action more direct and more strikingly manifested than in the movements of the atmosphere. Were the sun extinguished, and to become, as perhaps it may become long ages hence, a solid cold sphere, such as Byron imagined, "wandering darkling in eternal space," a few days would suffice to convert our mobile and ever-varying atmosphere into a stagnant pall, devoid of vapour, resting quiescent on a lifeless earth, held bound in a more than Arctic frost. From such a consummation, despite the supposed decaying energy of our sun, we may, however, entertain a reasonable hope that we are yet far distant.

Bearing in mind the all-embracing importance of the sun, let us see how the great movements of the atmosphere are determined by the way in which the earth presents its surface to the solar rays.

Since the quantity of solar heat received on each part of the earth's surface depends on the directness or obliquity of his rays—in other words, on the height to which the sun ascends in the heavens at noon—being greatest where he is directly overhead, as in summer in the tropics, it follows that the hottest zone of the earth is that in the immediate neighbourhood of the equator, and the coldest those around the poles.

Did time allow, and were the necessary appliances at hand, it would be easy to show you that both as a matter of experiment, and also as a deduction from physical laws, there must be under such circumstances a flow of air from the colder to the warmer region in the lower atmosphere, and a return current above. And to a certain extent we have these constant winds prevailing for about 30° on either side of the equator, in the trade-winds, which blow towards the equator in the lower atmosphere, and the anti-trades blowing in the opposite direction at a great height above the earth's surface.

In the neighbourhood of the equator there is a zone extending right round the earth in which the barometer is lower than either to the north or the south. It is due to the greater heat of the sun, and it is towards this that the trade winds blow. It shifts to some extent with the seasons, being more northerly in the summer of the northern hemisphere, and more southerly in that of the southern hemisphere; and its average position is rather to the north of the equator,

owing to the fact that there is more land in the northern than in the southern hemisphere, and that land is more heated by the sun than the ocean.

This simple wind system of the trades and anti-trades does not extend right round the earth, nor beyond 30° or 40° of latitude in either hemisphere. Were the earth's surface uniformly land or uniformly water, there probably would be a system of trade-winds all round the globe, blowing from both hemispheres towards the equator; but even in that case they would not extend much, if at all, beyond their present limits. In the first place, every great mass of land sets up an independent system of air currents, since the land is hotter than the ocean in the summer, and colder in the winter. In the summer, therefore, there is a tendency to an indraught of air from the sea to the land in the lower atmosphere, and an out-flow above, and in the winter the opposite; and this tendency modifies or interrupts the system of the trades and anti-trades. We have this tendency shown most distinctly in the monsoons of South-Eastern Asia, where, both in the India and China seas, a south-west wind in the summer takes the place which in the absence of the Asiatic continent would be held by a north-east trade-wind. And it is only in the winter that a north-east wind blows, and this is then termed the north-east monsoon.

In the second place, as I have said, the system of trade-winds could not in any case extend far beyond their present limits in latitude, owing to the fact that the earth is a sphere and not a cylinder. Let us fix our attention for a moment on the anti-trades—the upper winds which blow from the equator towards the poles. The equator, from which they start, is a circle about 24,900 miles in circumference; the poles are mere points, and, therefore, the whole of the air that blows towards the poles must turn back in any case before it reaches the pole, and must begin to turn back before it has gone very far on its journey. And, as a fact, a great part of it does turn back between 30° and 40° of latitude, which I have already mentioned as being the limit of the trade-winds. A part of the remainder descends to the earth's surface, and sweeps the Northern Atlantic and the North Pacific as a south-west wind.

On the chart which represents the average distribution of atmospheric pressure in January, there are two somewhat interrupted zones of high pressure over the ocean in these latitudes. These mark the regions in which the anti-trades descend to the earth's surface, and from which the trade-winds start. Over the ocean in all higher latitudes, both in the northern and southern hemispheres, the barometer is low—for the most part, indeed, much lower than over the equator; and the region intervening between the zones of high pressure and the seat of lowest pressure is that of predominant south-west, or at all events westerly, winds. Since our islands are situated on the border of this region of low pressure, south-west are our prevailing winds.

But now two questions arise: first, Why are these winds westerly, and not simply south winds? and second, How is it that the barometer is so low over the North Atlantic and North Pacific Oceans, and also in the southern hemisphere in high latitudes, seeing that in these latitudes, at least in winter, the sun's heat is so much less than at the tropics? The chart represents the state of things in midwinter of the northern hemisphere, and yet everywhere to the north of latitude 40° the deep blue tint indicates that the pressure is lower than even in the southern tropic, where the sun shines vertically overhead. Clearly this low pressure must be due to some other cause than the warmth of the air.

The explanation of this remarkable distribution of the atmospheric pressure, of the existence of two zones of high pressure in latitudes 30° to 40°, and of very low pressure in higher latitudes, except in so far as they are modified by the alternations of land and water, was first given by the American physicist, Prof. Ferrel. Its full demonstration is to be obtained only from the consideration of somewhat recondite mechanical laws, but a general idea of the causes operating may be gathered from very simple considerations, which may be demonstrated with a terrestrial globe.

Starting with the well-known fact that the earth revolves on its axis once in the twenty-four hours, let us see what will be the consequence, if we suppose a mass of any ponderable matter—that is, any substance having weight, no matter whether light or heavy—to be suddenly transferred from the equator to latitude 60° .

As the circumference of the earth at the equator is about 24,900 miles, any body whatever, apparently at rest at the equator, is carried round the earth's axis at the rate of 1,036 miles an hour. But in latitude 60° , where the distance from the axis is only half as great as at the equator, it is carried round at only half the same rate, or 518 miles an hour; and at the pole it simply turns round on its own axis. Supposing, then, a mass of air to be suddenly transferred from the equator to latitude 60° , with the eastward movement that it had at the equator, it would be moving twice as fast to the east as that part of the earth, and, to any person standing on the earth, would be blowing from the west with a force far exceeding that of a hurricane. It would be moving eastwards 518 miles an hour faster than the earth. Indeed, its movement would really be far greater than this. In virtue of a mechanical principle known as the law of the conservation of areas, which means that any body revolving round a central point, under the influence of a force that pulls it towards that point, describes equal areas in equal times, instead of only 518 miles, it would be revolving round the earth's axis 1,554 miles an hour faster than that part of the earth. I need not, however, specially insist on this point, because, as a matter of fact, the air which constitutes the anti-trades is not suddenly transferred, but takes a day or two to perform its journey, and in the meantime by far the greater part of its eastward movement is lost by friction against the trade-wind which blows in the opposite direction underneath it. The point on which we have to fix our attention is that, when the anti-trades descend to earth, they still retain some of this eastward movement, and blow, not as south, but as south-west or west-south-west winds.

On the other hand, the trade-wind, which blows towards the equator, is coming from a latitude where the eastward movement is less than at the equator, and its own movement eastward is therefore less than that of the surface over which it blows. A person, therefore, standing on the earth, is carried eastward faster than the air is moving, and the wind seems to blow against him from the north-east. Similarly, to the south of the equator, the trade-wind, instead of blowing from the south, comes from the south-east.

Thus, then, we have in both hemispheres a system of westerly winds in all higher latitudes than 40° , and a system of easterly winds—viz. the trade-winds—between about 30° and the equator; and if the globe were either all land or all water, these systems would prevail right round the earth.

Now, it is the pressure of these winds, under the influence of centrifugal force, that causes the two zones of high barometer in latitudes 30° to 40° , and the very low pressure in higher latitudes. It is not difficult to understand how this comes about. You are probably aware that the earth is not an exact sphere, but what is termed an oblate spheroid—that is, it is slightly flattened at the poles and protuberant at the equator, the difference of the equatorial and polar diameters being about 26 miles. It has acquired this form in virtue of its rotation on its axis. If you whirl a stone in a sling, the stone has a tendency to fly off at a tangent, and, so long as it is retained in the sling, that tendency is resisted by the tension of the cord. In the same way, every object resting on the earth, and the substance of the earth itself, has a tendency to fly off at a tangent, in consequence of its rotation on its axis, and this tendency is resisted and overcome by gravity. Were the earth not revolving, its form, under the influence of gravity alone, would be a true sphere. If it were revolving more rapidly than at present, it would be still more oblate, flatter at the poles, and more bulging in the tropical zone; if less rapidly, the flattening and bulging would be less.

This is precisely what happens with the west and east winds of which we have spoken. West winds are revolving faster than the earth, and tend to make the atmosphere more protuberant at the equator than

the solid earth; hence they press towards the equator, to the right of their path in the northern hemisphere, and this tendency increases rapidly in high latitudes. Easterly winds, on the other hand, tend to render the form of the atmosphere more nearly spherical, and they, too, press to the right of their path in the northern hemisphere or towards the pole. In the southern hemisphere, for the same reason, both press to the left. The result of these two pressures in opposite directions is to produce the two zones of high barometer in the latitudes in which we find them—viz. between the easterly trade-winds and the westerly winds, which are the anti-trades that have descended to the earth's surface. And the low barometer of higher latitudes is produced in like manner by the westerly winds pressing away from those regions.

Thus, then, we find that all this system of winds, and the resulting distribution of atmospheric pressure as indicated by the barometer, is the result of the sun's action in equatorial regions. It is this that gives the motive power to the whole system, so far as we have as yet traced it, and it is this that produces those great inequalities of atmospheric pressure that I have so far described.

It remains now to see how storms are generated by these westerly winds. In so far as they retain any southing, they are still moving towards the pole in the northern hemisphere—that is to say, they are advancing from all sides towards a mere point. Some portion of them must therefore be continually turning back as the circles of latitude become smaller and smaller. But they are now surface-winds, and in order so to return they must rise and flow back as an upper current. This they do by forming great eddies, or air-whirls, in the centre of which the barometer is very low, and over which the air ascends, and these great air-whirls are the storms of the temperate zone and of our latitudes. It is the ascent and dynamic cooling of the air in these great eddies that cause the prolonged rainfall of wet stormy weather. How the eddies originate, or, rather, what particular circumstance causes them to originate in one place rather than another, we can scarcely say, any more than we can say how each eddy originates in a rapidly-flowing deep river. Some very small inequality of pressure probably starts them, but, when once formed, they often last for many days, and travel some thousands of miles over the earth's surface.

Two such storms are represented on the charts of February 1 and 2, 1883, one on the coast of Labrador, the other to the south-west of the British Isles. The first of these appears on the chart of January 28, in the North Pacific, off the coast of British Columbia. On the 29th it had crossed the Rocky Mountains, and was traversing the western part of the Hudson's Bay Territory. On the 30th it had moved to the south-east, and lay just to the west of the Great Lakes, and on the 31st between Lake Superior and Hudson's Bay. On February 1 it had reached the position on the coast of Labrador shown in the chart, and on the 2nd had moved further to north-east, and lay across Davis's Straits, and over the west course of Greenland. After this it again changed its course to south-east, and on February 4 passed to the north of Scotland, towards Denmark, and eventually on to Russia.

The second storm had originated off the east coast of the United States between January 28 and 29, and on the following days crossed the Atlantic on a course somewhat to north of east, till, on February 2, it lay over England.

These storms always move in some easterly direction, generally between east and north-east, and often several follow in rapid succession on nearly the same track. It is this knowledge that renders it possible for the Meteorological Office to issue the daily forecasts that we see in the newspapers. Were it possible to obtain telegraphic reports from a few stations out in the North Atlantic, these storm warnings could be issued with much more certainty, and perhaps longer before the arrival of the storm than at present. In the case of such storms as that which reached our islands on February 2, we often have such warnings from America, but their tracks are often more to the

north-east, in the direction of Iceland, in which case they are not felt on our coasts, and hence the frequent failure of these American warnings.

It is the region of low pressure in the North Atlantic that is the special field of these storms. As they pass across it they produce considerable modifications in the distribution of pressure, but some of its main features remain outstanding. Thus there is always a belt of high barometer between storm region and the trade-winds, and in the winter there is almost always a reign of high barometer over North America, and another over Europe, and Asia, however much they may shift their places, and be temporarily encroached on by the great storm eddies.

These regions of high pressure are the places where the winds descend, and, as I mentioned in the earlier part of this lecture, these winds are dry, and generally accompany fine weather. On the contrary, the eddies, where the air ascends, are damp and stormy, and especially that part of the eddy that is fed by the south-west winds that have swept the Atlantic since their descent, and so have become charged with vapour.

And now we are prepared to understand why east, and especially north-east winds are generally so dry. They are air that has descended in the area of high barometer that, especially in the winter and spring, lies over Europe and Asia, and has subsequently swept the cold land-surface, which does not furnish much vapour, and therefore they reach us as dry cold winds. To begin with, the air comes from a considerable height in the atmosphere, and in ascending to that height in some other part of the world, it must have got rid of most of its vapour in the way that has been already explained. In descending to the earth's level it must, of course, have been dynamically heated by the compression it has undergone, but all or nearly all this heat has been got rid of by radiation into free space on the cold plains and under the clear frosty skies of Northern Asia and Northern Europe, and it then blows outwards from this reign of high barometer over the land, towards the warmer region of low barometer on the North Atlantic Ocean.

Thus we see that, in all cases, rain is produced by the cooling of the air, and that in nearly all, if not all, this cooling is produced by the expansion of the air in ascending from lower to higher levels in the atmosphere, by what is termed dynamic cooling. This last fact is not set forth so emphatically as it should be in some popular text-books on the subject, but it is an undoubted fact. It was originally suggested by Espy some forty years ago, but the truth is only now generally recognized, and it is one of the results which we owe to the great advance in physical science effected by Joule's discovery of the definite relation of equivalence between heat and mechanical work.

CONDITION OF MAURITIUS IN 1889.—The Report of the Chamber of Commerce concludes in the following terms:—

In conclusion it may be briefly remarked that, as the Colony has been spared the scourge of cyclones for some years past, its agricultural condition has improved, and although the Crop which may now be said to be almost gathered in will, contrary to general expectations at its commencement, show a deficiency compared with that of last year, the range of prices for all grainy descriptions of sugar have been on the whole remunerative, and the general position of Agriculture may be said to have gained strength during the year under review. On the other hand, there is unfortunately no marked improvement to record in Commerce. Operations in import business have continued to be conducted on a limited scale and at small profit. Judging, however, from statistics and reports from other commercial centres, there are evident signs of a steady improvement in commerce and trade generally, and it is to be hoped that, under the guidance of THE ALMIGHTY, the benefits of a revival in trade elsewhere may soon be extended to this Colony also and continue throughout the remaining years of the century.—*Mauritius Merchants' and Planters' Gazette.*

EXTREMES OF TEMPERATURE.—Mr. S. E. Peal writes us from Sibsaur on the 8th:—We have lately had the thermometer so low, that it seems worthy of being recorded. On the 2nd and 3rd instant at dawn in the open air—facing the East, it stood at 37 deg. F. and after Sunrise, when the sun was visible through the fog 39½ deg. In the sun at 2 p.m. the same thermometer rose to 132 deg. a range of 95 deg. and as I do not systematically examine the minimum or maximum I have little doubt it exceeded this. In the rains I have seen the temperature 172 in the sun, but a range of 95 deg. is not bad in one day.—*Indian Planters' Gazette.*

PEARL FISHING IN QUEENSLAND.—The report of Mr. W. Saville-Kent, F.L.S., F.Z.S., &c., Commissioner of Fisheries, on "Pearl and Pearlsell Fisheries of Northern Queensland," has just been issued from the Government Printing Office. It contains a general description of the fisheries, suggested regulations and concessions, an account of experimental operations by Mr. Saville-Kent, and concludes with a summary of the preceding chapters. From the report it appears that the average annual value of the Torres Straits pearl-shell fisheries for the past five years was £69,000. The report is illustrated by two plates.—*Queenslander*, March 1st.

CEYLON TEA FOR CANADA.—It is very satisfactory to know that apart from the Tea Company there are several individual planters engaged in pushing a tea trade in America. One of the earliest to find an opening for Ceylon teas in the Far West is Mr. Joseph Fraser of Damboolagalla, who for some years now, has been able to place a considerable proportion of his crop on the Canadian market. That the tea gives satisfaction may be judged from what Mr. Fraser writes to us:—

You will be pleased to hear that the Canada orders for tea continue to increase. I have to send away to this quarter during the next 6 weeks some 16,000 lb. The thanks of brother tea planters are due to Mr. Fraser and other gentlemen who, by finding new outlets for Ceylon tea, divert so much from the London market.

MINING AND GEMMING ORDINANCE.—We call attention to the discussion on this subject at the Chamber of Commerce. When we remember that Sir Arthur Gordon has had experience as an Australasian Governor, and that if ignorant of the terms adopted in the Gold Colonies, he could so easily learn the policy of the Madras authorities, it is passing strange that he should have allowed himself to be led by the nose by Mr. Wace. For, by none of the Colonial Governments—notwithstanding the temptation to make revenue out of their minerals—has there been so impracticable a proposal made as that just formulated by the Ceylon Government. The highest levy is a 2½ per cent royalty at the pit's mouth in the case of well-established mines in Victoria. Most of the other Australasian Governments as well we believe, as the Government of India, are agreed in accepting a moderate annual license and a leasing rent at so much per acre of land taken up. "To this complexion," most certainly must the terms under the proposed ordinance in Ceylon come.—Our attention is called to a curious fact by a correspondent: that "the Attorney-General seems to have overlooked the existence of the Ordinance 7 of 1882, which distinctly provides for licenses (with a rupee stamp) for lands that have been sold by the Crown and this I take to be the law of the land at the present moment. Mr. Grenier nowhere referred to this ordinance and it is not repealed by the new proposed ordinance."

THE 1,300,000 shares in the Amsterdam Assahan Tobacco Company, recently offered, have all been taken up. From the prospectus the following particulars are derived. The company intends to cultivate tobacco on grounds situated near the East Coast of Sumatra. The concession is for 5,000 bouws, and borders the river Asahan, which offers cheap facilities for importing materials and shipping produce from and to Tandjoeng Balei, which place is in regular steam communication with Java, Penang, and Singapore. The average price for the crop of 1888 was c.129, being after the Deli tobacco (149½) the highest price for all kinds of Sumatra tobacco. The concession is estimated at the value of 100,000 guilders in money and 50,000 guilders in paid up shares. Payment, however, of the shares is only required after a local examination of the director about the fitness of the soil for the cultivation of tobacco. He will proceed to Asahan for this purpose as soon as possible. In case his examination should turn out unsatisfactory the company will be liquidated at once. The Senembah Company is established in this city with a capital of f.1,500,000, divided in 1,500 shares, each of f.1,000. Subscription is opened on 400 shares, on which the dividend of 1889 will be paid. The company purposes to cultivate tobacco on the estates Senembah in Sumatra, of which the company has become proprietors.—*L. and C. Express*, Feb. 21st.

THE EAST INDIA CO.: TEA AND CEYLON.—In the interesting paper read before the London Society of Arts on 17th Jan. by Mr. Danvers, Registrar and Superintendent of Records at the India Office, we find the following reference to tea:—

By an Act of 1793, the trade was further continued until 1813, when the 53rd Geo. III., c.155, was passed, opening the trade with India to the public, at the same time reserving exclusively to the Company the trade with China and in tea. This latter trade was to continue to the Company until the 22nd April 1834, and by a statute of 28th August, 1833 (3 and 4 Will. IV., c. 93), the tea trade also was thrown open to the public, and the Company thereafter ceased to carry on any trade at all.

The earliest mention of tea in the old records is contained in a letter from Mr. Wickham, the Company's agent at Firando, in Japan, who, writing on the 27th June, 1615, to Mr. Eaton, at Miaco, asked for "a pot of the best sort of chaw." It is not certain when the first consignment of tea was sent home, but it appears that in 1664 the Company presented the King with a small quantity as a present; and three years later they directed their agent at Bantam to send "home 100 lb. weight of the best tea that you can get." Writing in 1684 to Madras, the directors stated:—"In regard, that is grown to be a commodity here, and we have occasion to make presents therein to our great friends at Court, we would have you send us yearly five or six cannisters of the very best and freshest tea." This was probably the commencement of the regular importation of that commodity into England.

Mr. Danvers referred to Ceylon as follows:—

A brief allusion may, not inappropriately, be made to Ceylon before concluding, as that island was once governed by the East India Company. The first intercourse of the English with Ceylon took place in 1763, when an embassy was sent from Madras to the King of Kandy, without, however, leading to any result. On the rupture between Great Britain and Holland in 1795, a force was sent against the Dutch possessions in Ceylon, when the whole of their forts fell into the hands of the English. At first the island was placed under the care of the East India Company and made subordinate to the Government of Madras, but in 1802 the whole seaboard of Ceylon became, by the treaty of Amiens, a possession of the British Crown, and its connection with the East India Company ceased.

A TEA VISTOR.—Mr. Hickling of the well known London tea firm and who, himself, holds considerable proprietary interests in the island is again on a visit to Ceylon, having come out in the "Britannia." We are glad to see Mr. Hickling well and vigorous and as full of encouragement as to the future of Ceylon teas as ever. Three years have elapsed since Mr. Hickling was out in Ceylon and he will see a considerable change in the growth of tea in the higher districts around Nuwara Eliya whither he proceeds in a few days. Mr. Hickling, we are glad to learn, thinks it very likely that Mr. Goschen (in view of his promise to Mr. Picton last year) will take 2d to 3d off the tea duty in his next budget. We are not likely to hear definitely before the middle of April probably; but meantime there can be no doubt that the home tea trade has been disturbed by budget anticipations.

THE GOVERNMENT CINCHONA ENTERPRISE IN JAVA.—The report by Mr. van Romunde, Director of the Government Cinchona Enterprise in Java, for the 4th quarter of 1889, and dated Tirtasari, 9th Jan. 1890, is as follows:—

The weather was characterized during the past quarter by alternate rains and drought. About the middle of December strong winds were experienced which did further considerable damage to the plantations at Nagrak by the tearing off of branches. The small quantity of continuous rain in the last months of the year is the cause why once again very plants have been put out as supplies or for renewing. Especially in the sandy soil of the Malabar range the young plants suffered greatly in consequence of the continually recurring drought, although few plants died, which must certainly be ascribed to the use of hardy seedlings. The crop of 1889 amounts to about 700,000 half kilograms of bark, of which by the end of December 560,507 pounds had been despatched to Tandjong Priok. The plague of caterpillars, of which mention was made in the preceding report, continued to be experienced during the month of October as well, and extended also to the estate of Rioenggoenoeng, where the insect was not noticed in former years. Neither trouble nor expense was spared in the catching of the caterpillars, and in order to combat the plague in the future the butterflies were as far as practicable collected and killed. The plague of caterpillars exercised a marked influence on the crop of the past year, as can be judged from the fact, that in the production of Tirtasari where bark is obtained entirely by thinning, only a slight increase is shown. As little bark as possible was taken from the trees on this estate in order to maintain a maximum mass of foliage in the gardens, with the happy result, that after the decrease of the insects soon nothing more was to be seen of the plague. As a means of if not extirpating at least reducing to a minimum the effects of the plague, perhaps the greatest that has yet visited the Government plantations, the maintenance of a dense condition of the plants seems to be the method indicated, and consequently cropping by thinning out has been as much as possible restricted on the other estates. On 5th Nov. and 5th Dec. sales of cinchona seed were held, which realised f2,475 and f569. By Government order of 16th Nov. 1889 No. 3 the minimum prices for ledgeriana seed were fixed at 20 cents and for succirubra and other seed at 10 cents per gram. On 5th Sept., 3rd Oct., 7th Nov. and 12th Dec. 1889 sales of cinchona bark of the crop of 1889 were held at Amsterdam. The unit prices reckoned per half kilogram bark and per cent quinine sulphate amounted at the last sales to 10 and 9 cents.

The number of plants in the Government gardens at the end of 1889 was 3,292,800, viz., in the nurseries 1,249,000—1,075,000 ledgeriana (including 15,000 grafts), and 174,000 succirubra; in the open 2,041,800—1,335,000 ledgeriana (including 230,000 cuttings and grafts and exclusive of the more or less 3,000 original ledgeriana), 3,300 calisaya and hassakarliana, 616,000 succirubra and caloptera, 63,500 officinalis, and 1,000 lancifolia.

ANNUAL REPORT ON THE GOVERNMENT CINCHONA PLANTATION AND FACTORY IN BENGAL FOR THE YEAR 1888-89.

Twenty-seventh Annual Report of the Government Cinchona Plantation and Factory in British Sikkim, being that for the year 1888-89, by BRIGADE SURGEON G. KING, M.B., L.L.D., F.R.S., Superintendent of the Royal Botanic Garden, Calcutta, and of Cinchona Cultivation in Bengal, and Officiating Government Quinologist.

1. The valley in which the plantation is situated participated in the dryness which was so general over the province during the earlier part of the season. But the effects of the unusual drought were but trivial, compared with the mischief caused by a violent hail-storm which occurred towards the end of the official year. By this storm many thousands of young plants in the nurseries were utterly destroyed. These plants had just been uncovered, in order that they might be hardened off prior to transplantation, and they were therefore little fitted to withstand a hail-storm of such extraordinary violence. Even the larger trees in the plantation by no means escaped. Their leaves were torn to shreds, and they will retain for some time the scars left on their smaller branches by the hail-storms.

2. *Changes in the Plantation.*—During the year, 395,003 trees either died or were uprooted for the sake of their bark. On the other hand, 353,730 trees were planted out. The renewals were thus slightly less numerous than the losses; but as the newly-planted trees are all yellow barks which yield only quinine, whereas those uprooted were red barks, yielding a mixture of quinine with cinchonidine and cinchonine, the alkaloidal value of the plantation has been very considerably increased. As will be seen by the table given as appendix D, the plantations now contain a total of 4,810,231 cinchona trees, of which nearly two-thirds are yielders of pure quinine. Seven years ago the proportion of pure quinine-yielders was but as one to four. The conversion of the plantation has therefore gone on pretty rapidly.

3. *The Year's Crop.*—The crop harvested during the year was the largest we have ever taken. It consisted of 207,460 pounds of red bark, 128,770 pounds of *ledgeriana*, and 36,870 pounds of other sorts, giving a total of 373,100 pounds. Of this total, 293,750 pounds were taken from the old plantation, 67,740 pounds from the younger one at Sittong, and 11,610 pounds from the youngest of all the Rungjung plantation in Bhootan. If the crop of the past year be added to those of previous years, the grand total of yield of these plantations since their beginning is brought up to 4,351,478 pounds of dry bark. During the year, 1,867 pounds were supplied on indent, or sold to Government institutions, the rest of the crop being made over to the factory as usual.

Against the expenditure there was harvested a bark crop of 373,100 pounds of dry bark, the cost per pound of which was therefore, as near as may be, 3 annas 1-333 pies per pound.

5. *Factory.*—For the factory the sum of R30,025 was the budget allotment for the year; but, as stated in the last paragraph, it was found necessary to ask for a transfer of the sum of R11,000 from the plantation. The actual allotment thus stood at R41,025; but of this only R37,304-15-6 were spent, a saving being effected of R3,720-0-6. The factory expenditure was swelled to this unusually large sum by the cost of providing the stock of fusel and kerosine oils required for working the new process for manufacturing quinine. A considerable expenditure was also incurred in new machinery for the same process. A further sum on account of machinery will, moreover, fall to be debited during the year we have now entered on. All the charges hitherto incurred for factory buildings, plant, and machinery have regularly been debited to working expenses, and I propose to debit all future charges to the same head. The factory has no capital account, as some critics of its expen-

diture seem to suppose, every charge having been regularly debited against the outturn of manufactured product. The outturn for the past year was 8,575 pounds, in the proportions of 2,191 pounds of sulphate of quinine and 6,384 pounds of cinchona febrifuge. If the price of the raw material be added to the factory expenditure, the total cost of the outturn is seen to be as follows:—

	Rs.	A.	P.
Factory expenditure on chemicals, labour, and machinery	37,304	15	6
Raw material, viz., 162,940 pounds of bark crop of 1887-88, at 4 annas 2-713 pies per pound	43,037	6	0
145,430 pounds of bark crop of 1888-89, at 3 annas 1-333 pies per pound	28,277	12	10
	1,08,620	2	4

In other words, the outturn cost, as near as may be, R12-10-8-08 per pound. As a matter of convenience, I have taken the cost of febrifuge and quinine as the same; for in the present transition stage of the factory it is difficult to disentangle the expenditure in labour and salaries, which has been incurred respectively on the manufacture of the two products.

6. *The New Oil Process for Manufacturing Quinine.*—This process has been in use for the manufacture of sulphate of quinine during the year, and no less than 2,191 pounds of that drug have been prepared by it. Arrangements have also been made for its application during the current year to the manufacture of cinchona febrifuge. Up to the year under review, the new process can scarcely be said to have been used on a manufacturing scale. But the production of 2,191 pounds is sufficiently large to entitle it to be fairly considered as a manufacturing experiment. This enlarged experience of the working of the process only increases our confidence in it. It works without a single hitch; the bark is entirely exhausted of the whole of its alkaloid; and the quinine produced is professionally reported to be as pure in quality and as satisfactory in appearance as quinine of the best European brands. A brief account of cold oil process was submitted by me to Government in March 1888, together with a short history of its invention. The history then submitted was, however, by an unfortunate inadvertence, inaccurate in some respects; and sufficient credit was not allowed for his share in its conception and perfection to Mr. C. H. Wood, who for many years was Quinologist on the plantation. Mr. Wood has now prepared a short history of the invention, and a full account of the method of working the process. And this important and interesting paper I now enclose as appendix A of this report. I again take an opportunity of bearing my testimony, not only to the excellence and simplicity of this admirable process, but also to the generous way in which Mr. Wood, without any pecuniary reward, initiated and invented in his private laboratory, while Mr. Gammie perfected it in the Government Factory. Without Mr. Wood the process would not have been invented, while without Mr. Gammie it would not have been successfully applied to manu facture.

7. *Sales of Febrifuge and Quinine during the Year.*—The total issues for the year were 6,178 pounds of febrifuge, 28½ pounds of crystalline febrifuge and 1,283 pounds of quinine.

The total issues of the previous year were 7,831½ pounds of febrifuge (common and crystalline), and 257½ of quinine. There was thus during the year a considerable falling off in the issue of febrifuge. But this is hardly to be wondered at when the extraordinarily cheap price of quinine in the open market is considered.

8. *Stock Account.*—The amount of bark in stock at the end of the year was 359,790 pounds, which has been valued at the cost price per pound of the year's crop. The other manufactured products have been taken at their cost price, and the chemicals and stores at their actual value. The total value of stock, calculated in this way, stands at R1,10,699-10-8.

9. *Financial Result of the Year's Working.*—Collecting the figures above given, the financial result of the year's working is seen to be a profit of R27,843-15-9.

This shows a net profit on the transactions of the year of R27,843-15-9—a result which, in the face of the unprecedentedly low prices for cinchona products which have ruled during the year, may, I trust, be considered as financially satisfactory. The chief cause of the extraordinarily low price which has for some time ruled for cinchona bark, and as a consequence for quinine and the other cinchona alkaloids, is the immense exportation of bark from Ceylon. When Coffee, which for a long time was the staple production of Ceylon, began some years ago to fail because of a disease which attacked the coffee tree, cinchona was largely substituted by the planters of that colony for the failing staple. And some idea of the extent to which this was done may be gathered from the following figures. During the year ending 30th September 1880 (using round numbers), one and-a-quarter million pounds of cinchona bark were exported from Ceylon to London. During the year 1883-84 the quantity rose to eleven millions, and the following year the quantity was about the same. During 1885-86, fifteen million pounds, and during 1886-87, fourteen million pounds were exported. In 1887-88 the quantity fell to eleven millions, and during the current year it is expected to show a further fall. The explanation of all this is simply that, when cinchona began to fail from disease and depreciation in quality, the Ceylon planters turned their attention to tea-planting with such energy that they cut down their cinchona trees to make way for tea bushes; and, not being able to hold their bark, they were obliged to force it on the London market, to be sold for what it would fetch. The result has been an enormous fall in price, bark having been freely obtainable in London for several years past at prices considerably below the cost of production; and quinine having, as a consequence, fallen to a figure far below any thing previously heard of. The exportation of bark from Java has also greatly increased of late years. South American bark, which a few years ago was our only source of quinine, has practically been driven out of the market. And the world has thus been drawing its supplies of quinine for some time past, chiefly from bark grown in British and Dutch colonies in Asia. The efforts of the Governments of Great Britain and Holland, to secure for their tropical subjects a cheap remedy for the commonest of all tropical diseases, have thus culminated in a more triumphant success than was ever anticipated. But this state of affairs cannot last much longer. Ceylon planters will not go on planting cinchona trees to sell their product at a loss. As a matter of fact, planting has already ceased; and exportations are beginning to diminish. And, in the course of a year or two, the price of cinchona products must rise. The invention of the new oil process of Messrs. Wood and Gammie, and the free publication of it by Government, will no doubt contribute materially to maintaining them permanently below the rates which have been hitherto considered as normal prices, because this invention makes it possible for any intelligent planter to make quinine on his own estate. From the general depression of the cinchona industry, the Government estate could not hope to escape; and from a commercial point of view, the past year has not been so good as many previous years when prices were high. But inasmuch as quinine has been materially cheapened (and thus put more within reach of the masses), the result is, I think, gratifying.

10. The crop of bark for the coming year will be regulated by the demand for quinine and febrifuge. And, as by the new process of manufacture a much larger outturn of alkaloid is obtained from the bark, the annual draft in the plantation for raw material should now begin to diminish.

11. The sum of R2,150 received from the settlers within the cinchona reserve for land rent and grazing dues was paid into the Darjeeling Treasury, and no credit is taken for them in the plantation accounts.

12. The growth of the fuel plantation has been remarkably good, and the experiment, so far as it has

gone, has been an unmitigated success. A small addition to its area was made during the current year. From the older parts of this plantation it will soon be possible to thin out a good many poles for building sheds and coolies' huts.

13. For the seven months of the year under review, I was absent on furlough, and my duties were performed by Mr. J. Gammie, the Deputy Superintendent. Mr. Gammie's service are already too well known to Government to require anything more than mention by me. Mr. Pantling, Mr. Parkes, and Mr. Gammie, junior, conducted their respective duties to Mr. Gammie's satisfaction and to mine. The head-writer in the Cinchona office, Baboo Gopal Chandra Datta, and the second writer, Baboo Devendra Nath Basu, and the other members of the office staff, have also worked diligently and well.

14. The usual statistical returns, together with Mr. Wood's memorandum on the new process for making quinine, are submitted as appendices.

APPENDIX A.

Memorandum on the Fusel Oil Process of Manufacturing Quinine, by C. H. WOOD, ESQ., F.C.S., F.I.C., &c., &c., late Government Quinologist to the Government of Bengal.

At the time I received the appointment of Quinologist under the Government of Bengal (1873), I was instructed by the Secretary of State to give my chief attention to the production on a large scale of a cheap and efficient febrifuge from the cinchona bark grown in British Sikkim; and I was specially directed to consider the suitability of the method which had been proposed by Dr. De Vriij for this purpose. It was in accordance with these instructions that the manufacture of the preparation now known as "cinchona febrifuge" was established at Mongpoo. This preparation is made exclusively from the bark of *C. succirubra*, which at that period was the principal product of the plantations. The process selected for its manufacture was not well adapted for extracting the alkaloids from the more valuable bark of *C. calisaya*. Several varieties of this species, however, were then under extensive cultivation, and a considerable supply of bark from this source was likely to follow. The manufacture of cinchona febrifuge from the produce of *C. succirubra* being well established, it became important to make arrangements for working up the *calisaya* bark by some other method.

It was obvious that the most satisfactory way of utilizing this bark would be to prepare from it pure sulphate of quinine; but this could not be economically done with such crude appliances as sufficed for the manufacture of febrifuge. A suitable building furnished with the requisite machinery and apparatus was considered to be essential, and representations to this effect were made to Government by Dr. King and myself. Accordingly, in 1879, the Government of Bengal had agreed to sanction the formation of a small factory for the manufacture of pure quinine from the *calisaya* bark. Experiments which had been in progress for some time had enabled me to select a process for the purpose which promised to give satisfactory results. This process was to receive an extended trial in the new factory. The principal details of the method of working had been settled, and rough sketches of the apparatus made. The solvent I proposed employing in extracting the alkaloids from the bark was the "fusel oil" of commerce. This substance is a bye-product obtained in the manufacture of spirit, and could be then purchased in London at about 9d. per gallon. I presume it has acquired the name of "oil," because it floats on water, but its chief chemical component is *amyllic alcohol*. There was no likelihood of any difficulty in the importation of fusel oil from Europe for use in the process; but should any unforeseen obstacle arise whereby fusel oil could not be got, ordinary spirit was to be used in the extraction, and Government had sanctioned its exemption from duty for such purpose. I had abundant evidence that the whole of the alkaloids could be advantageously obtained from the bark by the process I had selected;

but its economical employment on the large scale depended on the use of suitable apparatus whereby the solvent could be recovered from each operation with very little loss. It was for this reason that I considered a properly furnished factory to be essential to success; and, as I have stated, the Government was prepared to sanction the expenditure necessary for this purpose.

At this time then the arrangements were matured for starting a factory and putting the fusel oil process in operation. But at the same period there were reasons of a personal kind which made me anxious to return to England, and on this account I wished to tender my resignation. It seemed to me a suitable time for taking this step, because any successor to my appointment having to take the superintendence and control of the manufacture, would naturally prefer that the factory and its appliances should be arranged under his own direction. Some informal correspondence on these points passed between the Lieutenant-Governor and myself, in which Sir Ashley Eden at first very kindly asked me to reconsider the course I wished to take; but ultimately my resignation was accepted. It was suggested that the Secretary of State would possibly select a young chemist for the appointment, who would be willing to take up and carry out the plans already made for starting the manufacture. In that case I undertook to work with him on the subject for a time in London, and render him what assistance I could in acquiring information that might be useful to him in putting the process into operation.

I returned to England in the autumn of 1879, and a few months later I had an opportunity for making myself further acquainted with the employment of mineral oils in the extraction of quinine. The use of these agents had been already tried in India. Mr. Broughton experimented with them, but did not obtain any economical success (see his Report, dated 1st December 1873). Some experiments with such oils had been also made by myself, but with no very satisfactory results. Nevertheless, in some of the principal quinine factories of Europe, a process of extraction with mineral oil was being employed. Indeed, the oil process had largely superseded all others. I found that only certain kinds of oils, namely, the paraffine oils obtained in the distillation of "brown coal," or schist, were well adapted for this process, the products of American petroleum being unsuitable for the extraction of quinine. I procured some oil from Young's Paraffine Works, and made some trials with it in the extraction of calisaya bark from the Sikkim plantations, and obtained much better results than I had done before. Nevertheless, it appeared to me that the employment of this process in India would be attended with considerable difficulty.

Fusel oil still presented to my mind many advantages for use in that country, but I began to see the way to a further simplification in the method of employing it. In the process I had selected in India, fusel oil alone was used as the solvent. It now occurred to me that by previously diluting it with some liquid hydrocarbon a considerable improvement would result. In this case the fusel oil would be the active solvent; but the presence of a considerable proportion of a hydrocarbon, such, for instance, as any mineral oil or naphtha, would exclude some of the impurities otherwise taken up by the fusel oil when used alone, and the alkaloids would be at once obtained in a much greater state of purity. I soon satisfied myself that the employment of a mixed solvent of this description would have many advantages over the use of fusel oil alone. But a considerable time had elapsed, and no fresh appointment to the post of Quinologist had been made. I learnt that the Government did not consider it desirable to send out another chemist. Under these circumstances, I was not in a position to make any further suggestions regarding the process of manufacture at Sikkim, and I therefore let the matter drop.

Later on, however, I heard that Mr. Gammie, who still conducted the manufacture of febrifuge, was also attending the manufacture of pure quinine sulphate from the calisaya bark; and a correspondence began between Mr. Gammie and myself on this subject. At

about this time Dr. King came on a visit to Europe, and in the autumn of 1884, I had an opportunity of discussing with him the practicability of the efforts Mr. Gammie was making at Mungpoo. At that time a spirit process was under trial, and the results promised considerable success. The alkaloid was completely extracted from the bark, but it was associated with much impurity, and its purification rendered the process somewhat too complicated for use on the plantations. Dr. King, during his stay in Holland, had acquired some valuable information regarding the paraffine oil process as used in the Continental oil factories, and he consulted me regarding it. I was impressed with certain difficulties, which I thought would attend its employment by Mr. Gammie, and I did not feel that I could then assist him much in that direction. It seemed to me, however, a favourable moment to make a further trial of the modification of the fusel oil process to which I have already referred, namely, the employment of fusel oil diluted with some liquid hydrocarbon for the extraction of the bark. Accordingly, I resumed my experiments on the use of such a mixed solvent, and worked out two or three alternative processes. These differed from each other chiefly in the nature of the diluting hydrocarbon. In one, the mixed solvent was formed by diluting the fusel with five or six times its volume of the volatile portion of coal tar naphtha. The principle of this process I communicated to Dr. Radwood, one of the editors engaged in preparing a new Pharmacopœia, as likely to furnish the basis of a convenient analytical method for determining the alkaloidal value of the cinchona bark used in medicine, and the process is now the official test for that purpose in the present British Pharmacopœia. The use of a volatile naphtha, whether derived from coal, shale, or petroleum, for diluting the fusel oil, presented several advantages for a manufacturing process; but it was probable that there would be great difficulty in obtaining any such naphtha in India. In another of the processes I devised, the fusel oil was therefore diluted with ordinary kerosine. As this oil is so largely used for illuminating purposes in India, and is therefore so readily obtainable there, this method offered the greatest facilities for immediate trial.

When Mr. Gammie visited England in the summer of 1885, he came to my laboratory and witnessed the experimental working of this process; and formed a favourable opinion of its adaptability for use on the plantations. On his return to Mungpoo, he began a trial of the method in extracting calisaya bark, and the satisfactory results he obtained encouraged him to go on. With great perseverance he mastered one detail after another, using only the simple appliances that he found at hand, until he was able to employ the process on a considerable scale. The valuable results, therefore, which have been thus far attained in the practical application of the process, are entirely due to his skill and energy.

A description of the process as it was being conducted at the commencement of this year was drawn up by Mr. Gammie, and was published with the Government Resolution of the 26th March 1888. Since then, I believe, he has effected a further improvement in the mechanical arrangements, and is now in a position to work from 3,000 to 5,000 lb. of bark per week. A considerable quantity of quinine sulphate has been produced and issued. Samples of this have been analysed, and the results show that both in purity and appearance it is equal to the best European quinine. There appears to be no doubt that the extraction is complete, the amounts of quinine obtained corresponding well with the known composition of the bark.

As yet only calisaya bark has been worked by this process. This bark contains a large amount of quinine associated with very little cinchonidine; consequently the final operations for obtaining pure quinine sulphate are very simple. But the plantations will also furnish much bark, especially from hybrids, which contains a considerable amount of quinine associated with a large amount of cinchonidine. Such bark will no doubt be utilised in the preparation of pure quinine as soon as the further arrangement necessary for separating

he extracted alkaloids are provided. Succirubra bark can be as readily extracted by this method as any other; and it seems that from the acid solution of the total alkaloids so obtained, "cinchona febrifuge" can be prepared equal in every respect to that hitherto prepared by the acid process, and with the advantage of a greatly increased yield.

Comparing this process of extraction with others that have been tried in India, the chief advantages it presents appear to be—(1) that the alkaloids are completely extracted from the bark in a much greater state of purity, so that the final operations for obtaining pure and finished products are much simplified; (2) that the whole process of extraction can be performed at common temperatures; (3) that the apparatus and appliances required are all of a simple character, and therefore well suited for use on the plantations.

No very exact estimate can yet be formed of the cost of manufacturing quinine and other alkaloids by this process. It is only now slowly passing from the experimental stage, which is necessarily an expensive one. Further improvements conducing to greater economy are probable. But even as it is, I gather from Dr. King, under whose skilful superintendence all efforts at local manufacture have been so ably fostered, that quinine can be produced on the plantations at a cost not exceeding the present unprecedentedly low market price of the valuable medicine.

THE GERMAN NEW GUINEA COMPANY has recently been making trials with a view to growing cotton in Kaiser Wilhelm's Land, and I hear that their efforts have been highly successful. A sample of the new produce found a good market and realised much above the average price. In March about 500 cwt. are expected of the new article.—*Cor., L. and C. Express*, Feb. 21st.

GUM ARABIC IN PERSIA.—It is well known how the recent wars in the Soudan and the isolation of those tracts have affected the supply of gum. The effects of this are now being felt in Persia, where gum is now being extensively collected from the wild almond, "gavan," and other shrubs and trees, and measures are being taken to prevent the wholesale destruction of such woods.—*Chemist and Druggist*, March 1st.

CAPITAL WANTED FOR BOLIVIAN CINCHONA PLANTATIONS.—A letter has been sent to the French Agricultural Society from La Paz, Bolivia, stating that in the Yungas district cinchonas are cultivated which afford as much as 8 and 10 per cent. of quinine. The younger barks are best, the alkaloids therein increasing in proportion until the trees are six years old, after which the valuable constituents decrease as steadily, fine-looking flat old barks, about 4 inches in width, sometimes containing only 1½ per cent. of alkaloids. The richest sorts are quills about the size of the finger. Shoots springing in great numbers from old trees which have been cut down invariably hold considerably more quinine than the parent tree. Hence the once accepted opinion that older barks are best is erroneous. On the contrary, the younger ones, or *canutas*, are preferable; while to secure the largest yield cinchonas should be grown from seed, and cut down when between six and twelve years old. The idea of growing cinchona forests is, for the same reason, an unwise one. The letter goes on to urge Europeans to come to Bolivia and there purchase lands, which can be had very cheaply, for developing the cinchona industry on a substantial basis. The communication, although perhaps not disinterested, is of some interest as affording an insight into the modern Bolivian methods, which in many ways differ from the East Indian mode of conducting cinchona plantations.—*Chemist and Druggist*.

DEAR QUININE AT HOME.—An Uva correspondent writes:—"I do not think I told you that inquiring at the retail chemists for quinine by the ounce, I found their prices ranged from 3s to 12s in London, 6s in Torquay, and 5s to 5s 6d in Winchester. On the 12s man telling me his price, I said: 'You are of course aware that quinine is selling at considerably below 2s the ounce at Mincing Lane.' 'Yes, so it is,' was the reply. Quinine alone was the remedy—all the substitutes were found useless—against the influenza." And yet the quinine people seem not to have risen to the occasion: did they placard all the big towns with "Penny Quinine—the only preventive of Influenza" &c. &c.? We grow not—or the market would have got into a better position.

DYSPEPSIA IN TOWN FOLK.

Probably few things do more to determine a man's disposition than the state of his digestion. The ancient philosophers maintained that they could produce any given disposition by controlling the diet. Certain kinds of minds go with certain kinds of bodies, and, in a large measure, is the body influenced by the diet. Compare the fat, well-fed, phlegmatic priest with the active, under-fed, nervous needle-woman; compare the hardy and enduring eaters of whale blubbers with the eaters of fruit; compare the adipose beer-drinker with the tormented gutton; and in all these cases, and, indeed many others, there will be seen marked differences. On the whole, generally speaking, there are no people fed so well, as a class, as the dwellers in towns. More meat is eaten in London than in any city in the world, and its inhabitants show great force. The general strain put upon them requires that they live well; but with all this strain the digestion is somewhat enfeebled, and the food necessary to keep up the body taxes the digestive organs too. But there are other things. Sanitary science teaches that only a certain number of people can live, without detriment to themselves, on an acre of ground. In large towns this principle is entirely disregarded, and all the dwellers have to participate in paying the penalty, either with their own health and shortened days, or with that of their children yet unborn. One fact is significant: the ozone in it with in the air after a thunderstorm is valuable, in that it exerts a purifying action upon the atmosphere. In London it is quite impossible to find traces of this ozone.

We say that dyspepsia is an accompaniment of civilization, and the proposition is so plain that he who runs may read. Its symptoms are multifarious, but one thing is an unmistakable evidence of its presence, which is the subjective feeling that one has a stomach. To *feel* you have a stomach is dyspepsia. It is a disease whose pains are relentless and unmanaging, and whose consequences are grievous to be borne. In most cases, consumption, cancer of the stomach, ulcer of the stomach, and, in infants, rickets, scrofula, and general wasting, are preceded by dyspeptic conditions.

What is the cure? There is no one thing will cure it. Pepsin Tabloids, one or two after each meal, are the best digestive aid, and if there be flatulence, these should be accompanied with five or six Charcoal Tabloids. One point should ever be borne in mind: "as long as there is constipation the dyspepsia cannot improve, and, to correct this, Cascara Sagrada is admirable. It does not aggravate the trouble the longer it is given, but, on the other hand, eventually overcomes. At first, a Tabloid may be required two or three times a day, but a period soon arrives when less and less, and finally none, is needed. For acidity, half a dozen Soda Tabloids, swallowed with a draught.—"Health," London.

Correspondence.

To the Editor.

CEYLON EX PLANTERS IN CALIFORNIA.

"Malcolmson Vineyard," Fresno,
California, Feb. 5th.

DEAR SIR,—Your ever welcome *Weekly Observer* is now coming to hand regularly, and by the time I got it back again owing to the numerous old Ceylon planters' hands it goes through, it is almost in shreds so eagerly is it devoured. Some of us here are longing for the time, when our vineyards are in such condition as regards crops, that we can pay a visit to the old island, but in the meantime we have to do our best to pull along until that time. If you think a description of this locality and our vineyards—and in this vicinity we have some of the largest in the world—would be of interest to your numerous readers, I shall willingly sit down and give some idea of our prospects here and the country generally. In the meantime, I may mention we have located amongst us in this vicinity one of the ablest botanists in this State and one who has given a considerable amount of time and with success to the eradicating of the vine disease, a disease something similar to the dreaded *Hemileia vastatrix*. So successful has he been in this particular branch that he has lately placed himself in communication with your respected Colonial Secretary, who has I understand brought his name before your Planters' Association. This gentleman, Professor Gustave Eisen, is well known here and is one of very high authority, and he feels certain if sufficient inducement is held out to him that he could eradicate your old enemy, the coffee leaf disease. Should his letter be favourably entertained by the Association and he decide to go to Ceylon, I shall be happy to hand him letters of introduction to your good self as also to my numerous friends in Ceylon.—Yours &c.,

WM. LAING MALCOLMSON.

[We should not advise the Professor to think of incurring the expense of a visit to Ceylon to experiment on *Hemileia vastatrix*. The area now left of coffee is very limited, and it is scarcely at all troubled with *H. V.*, the chief pest now being a coccus insect, *green bug*. We shall be glad to hear about the vineyards.—Ed. T. A.]

CEYLON TEA IN NEW SOUTH WALES.

General Post Office, Sydney, Feb. 7th.

DEAR SIR,—Since arriving here I have been endeavouring to "push" the Ceylon tea (and commenced business as agent in a small way "as per enclosed card"), but hitherto have received scant encouragement owing to the flavour of the tea I brought with me, not being generally liked. People complain of its strong flavour, and I think most of the Ceylon teas are faulty in this respect, as I find our teas are being "blended" with inferior China teas, to a very large extent, and principally on this account retail grocers buy the strong flavoured Ceylon teas at a low figure and it is passed on in a blended form to suit the public taste, so that in reality the Ceylon tea is little known and less appreciated in its pure state. Were a weaker or finer flavoured tea obtainable, it would undoubtedly fetch a better price and would be more appreciated and sought after by private families, and there would be no occasion for blending with other, and as is often the case, with inferior teas. As far as my experience

goes the Ceylon teas are bought up entirely for blending purposes, I allude now to the town trade.

If you would kindly say a word on my behalf, getting the Planters' Association to appoint me one of their agents in Sydney and if they would supply me with samples of tea for distribution, allowing me a certain percentage on all orders obtained, I would feel greatly obliged to you and would do my best to forward their interests. I would, however, strongly recommend them to consider the advisability of obtaining finer or less strongly flavoured teas for the Australian market, as it is of the greatest importance to get our teas appreciated for domestic use, in its pure state and not for "blending" purposes; as in the former case better prices are obtainable.

Another proposition I wish to make is, that the P. A. have their tea "analyzed" by a competent and well known Australian chemist, and copies of the analysis to be distributed amongst agents and others out here. It would aid the gentlemen who are trying to push the tea, and would also be a good recommendation, especially if a note by you, the editor, were added to the analysis.—Yours &c.,

L. P. THOMAS.

P.S.—Should my brother planters aid me in the way I have indicated in the disposal of their tea in Australia, I should do what I could for their interests. Not forgetting to thank you sincerely for all you have done for us and all who so liberally aided us in taking this much desired change, which as far as health goes has proved beneficial. I like Australia, and Sydney is a fine city, but sanitary reforms are much needed, particularly in the suburbs.

L. P. T.

[As the readiest means of aiding Mr. Thomas we give publicity to his letter, which the Ceylon Tea Fund Committee will doubtless take into consideration. Ceylon teas were fully analyzed in Melbourne at the time of the Exhibition. Has Mr. Thomas warned consumers of pure Ceylon teas to put less in the pot, and to be careful not to allow the infusion extend beyond 5 or 6 minutes?—Ed. T. A.]

EMPLOYMENT BY THE IMPERIAL
BRITISH EAST AFRICA CO.

Mombasa, Feb. 11th.

DEAR SIR,—As I have had sundry inquiries from men in Ceylon, as to what steps should be taken to obtain employment in this Company, I should be much obliged if you would insert this letter in your valuable paper.

All appointments are made in London. Personal application must be made at the office, No. 2, Pall Mall East.

The limit of age is I believe from 25 to 35 years. The Board strongly objects to married men.

It would give me much pleasure to see Ceylon men out here, but I should strongly advise them not to go home in hopes of getting employment here.—I am, sir, yours faithfully,

J. R. W. PIGOTT,

Asst. Administrator,
Imperial British East Africa Co.

THE COCONUT LEAF DISEASE.

Veyangoda, Feb. 16th, 1890.

DEAR SIR,—In your issue of the 13th instant, in drawing attention to Dr. Trimen's latest report on the Coconut Leaf Disease you say "we are assured that it has almost, if not quite, disappeared from nearly every district where it was temporarily noticed, unless Veyangoda be an exception." You will I am sure excuse me if I inquire whether the assurances you refer to were

made to you by the residents of every district where the disease was once present, or whether you received them at second hand. Assurances such as you refer to must be received with caution, for people very often when speaking only for themselves pretend to hold a brief for others as well. Writing somewhere in March last year your veteran correspondent from Hapitigam Korale gave you a description of the disease as observed by him, "on the two to six year old plants now suffering, the whole of the leaves, in some cases even to the half developed centre shoot, are affected, and the dark specks appear not only on the leaflet but on the leaf-stem itself," a pretty minute description of the disease that. Writing later on and after rain fell he says, "the coconuts have taken a fresh start. Many of those that suffer from the disease have developed centre leaves without a speck, but we must not holla till we are out of the wood." And yet when the now historical deputation waited on you, Mr. Wright is reported by you to have said "throughout the Hapitigam Korale there is no appearance of any disease." Mr. Wright's statement, if correctly reported, and he has never contradicted it, is in direct opposition to that of your Hapitigam Korale correspondent. It is clear that on that occasion Mr. Wright spoke only for himself, though he appeared to represent the whole of the Korale he is resident in unless W. B. L. be credited with a very vivid imagination in describing what was non-existent.

As last year so this year, the disease made its appearance in October-November, and during the hour or so that Dr. Trimen spent in going round the estate from which I write, I was able to show him that trees on adjoining estates were affected as well as those on this I am of a very sceptical turn of mind and refuse to believe that as regards the disease this district is an exception, till I have personally satisfied myself as to the truth of it. Last year I travelled pretty freely and found the disease present wherever I went. I would fain hope that your surmise that the coconut leaf-disease like that of the cinchona and gum is due to chemical causes is correct.—Truly yours, B.

["B." should now give up groaning over the past, and take a brighter view of the present and future; at least our accounts from most coconut districts are most cheering.—Ed. T. A.]

"TEA IN THE UNITED STATES."

SIR,—Referring to your paras under this heading, in your issue of the 3rd and 4th instant, I cannot reconcile the figures with those given to us by the eminent tea tabulating firm of Messrs. Gow, Wilson & Stanton. According to this firm's last annual (colored) circular, I find it stated that the "annual average consumption of tea in English pounds" in the United States to be as follows:—

1883-84	87½ millions
1885	66½ "
1886	79 "
1887	87½ "
1888	84 "

Your figures tell us that "the value of tea imported (into the U. S.) has gone down" as follows for 11 months in each year;—

1884	13,000,000 dollars
1886	14,179,000 "
1889	10,658,000 "

Say roughly for 12 months in each of the above years:—

1884	14 million dollars
1886	15 "
1889	12 "

So that in 1884 and 1886 the value of the tea imported into the U. S. was apparently 16 cents and 19 cents per lb. respectively, or say, roughly, in English money 7½d and 9d per lb. only.

If my figures for value are deduced correctly we must certainly not expect the people of the U. States to buy our fine teas until they have become educated up to them. Mr. Pineo ought, be

this time, to be able to tell us if it is true that about 8d per lb. represents the average wholesale price in America: if so it is astoundingly low seeing that no duty on tea is levied there! and if in 1889 there were again, as in 1888, 84 million of lb. imported and at a cost of 12 million dollars only, then the value per lb. was in 1889 only about 14 cents, or say about 6½d per lb.!

It is very evident from the fact of the people of the U. S. now paying almost double the value for the coffee they drink compared to what they did in 1884, that they only require to have the right kind of tea placed before them to buy it greedily; any way money apparently seems to be no obstacle. Like the people of England they are doubtless rapidly refusing to drink the cheap and nasty teas now being sent to them by China and Japan; and when they can get pure Ceylon tea at a moderate price and know how to brew it, we may expect to see the consumption go up by leaps and bounds. Mr. R. E. Pineo should hurry up and never mind

OOLONGS.

[To which we add that Mr. Pineo should try and get at the millions among European emigrants, regular tea drinkers, who have passed into the United States since 1859 say, and who should still know good tea when they see and try it.—Ed. T. A.]

THE GAME PRESERVATION MOVEMENT.

Outstation, March 1st.

SIR,—In running over the list of persons who have joined the Game Preservation Association, I was very much surprised to find that only three Civil Servants have given their support to the object in view; and that not a single native sportsman (of whom there are very many in the island) has apparently been asked to co-operate. I fully believe that if the latter had been approached on the subject, very many, who hold the same views on the subject of sport, as European sportsmen, would, I doubt not, have gladly worked shoulder to shoulder with those who originated the movement. I can't trust that my view as regards the exclusion of native sportsmen is not correct.

I daresay it will be some months before we can expect a special legislative enactment to be passed on the lines suggested by the Association, or on the basis of the very able Report laid before the Legislative Council by the Commission headed by Major-General Lennox. In the meanwhile, it is hoped that those Civil Servants who hold office in such well-known game centres as Anuradhapura, Mannar, Jaffra, Batticaloa, Trincomalee, Hambantota, Matara, Tangala, Puttalam, Chilaw, Kurunegala, and Vavuniyanvilankulam will see that the existing law (though very defective in some respects) is enforced and that their petty headmen do not connive with the native sportsmen of their villages in the extinction of one of the sources of the food supply of the Colony. It is, I believe, not generally known that the Government Agent or Assistant Agent of each Province or District holds every month a kind of durbar of all the headmen under him when questions of irrigation, forest preservation, crime &c. are discussed. Would it be out of place if these Civil Servants would make it a point, on such occasions, to impress on the minds of their headmen the pressing necessity of observing a close time and enforcing the clauses of the existing Game Preservation Ordinance? This might be done till a more satisfactory ordinance is passed by our Legislature. I believe it will be best for the Association to communicate with all the Civil Servants in the island, asking them to form branch associations in their districts. These might hold their meetings a fortnight or so before the meeting of the parent Association, and the resolutions passed by them might be forwarded for consideration and discussion at the general meeting to be held at Nuwara Eliya.—Yours faithfully,

NIMROD.

ALOE FIBRE FROM SOUTHERN INDIA.

Halgar, Coppa, Kadur District,
Mysore Province, March 1st.

DEAR SIR,—In your *Overland* edition of the 11th December last I read a very interesting article regarding fibres and fibre-cleaning machines. By this day's post I am sending you a small sample of fibre I have prepared from the aloe leaf common to this part of the country. I should feel very much obliged to you if you would let me know at what prices such fibre would be sold and also how it should be packed, also if there are any cheap machines for extricating the fibre from the leaf.

Hoping you will excuse me for the liberty I am taking in writing you on this matter and any trouble I may be giving you, I am, dear sir, yours faithfully,
L. D. COLLEDGE.

[The fibre looks good and marketable, but we regret to say there is no trade in the article as yet at Colombo, nor any means of having its value appraised. We see the latest quotations for aloe fibre in Mauritius is:—

1st Quality R375 to R400 per ton.
2nd Do R350 to R360 do.

We would recommend our correspondent to apply to Mr. Thurston of the Madras Museum, or to the Superintendent of the Gardens at Saidapet, for information.—Ed. T. A.]

LOCAL LIMITED PLANTING COMPANIES.

Uva, March 6th.

DEAR SIR,—I have perused with much interest and considerable profit the reports and balance sheets of the several local Limited Companies you have lately been publishing in the *Observer*. These reports have been specially interesting to me as I have been asked by a friend to look out for a safe investment in a good paying Company, so that any information that can be gathered is carefully noted. These reports convey a very candid if not a very good account of the Companies' affairs at present; but the directors are to be highly commended for laying such a very honest and explicit statement of matters before the shareholders and the general public (take for instance the Uva, Spring Valley and Lanka Companies in Uva).

There are two large and influential Companies in Uva, "The Haputale Coffee Company, Limited" and "The Madulsima Coffee and Cinchona Company, Limited," which every now and then one hears great things of locally, but which you keep us terribly in the dark about. I cannot remember ever having seen a copy of their profit and loss account in any of the local papers, and this makes me rather curious to know why these two Companies don't publish an annual statement of their affairs like what all other local Limited Companies do. It has been mentioned to me that these Companies are doing so well that the directors and shareholders wish to keep the thing within themselves. (Surely this is not so.) How far this may be true I don't know, but still I am sure this need not prevent them from furnishing the outside world with a statement of their revenue and expenditure since the Companies were started. It can do no harm, and will attract the attention of capitalists to Uva as the field for good sound investments in coffee, tea and cinchona. It is not a lot of big talk that is wanted, but facts and figures, so let us have a copy of the balance sheet of these two Companies, if you can obtain them, so that we can compare them with other local Limited Companies in our midst which no doubt will be for the good of these Companies' interests and our new Province in particular.—Yours truly,
SNOOKS.

ADVERTISING TEA IN CANADA:

THE WAY THEY DO IT.

Colombo, March 8th.

DEAR SIR,—One of our constituents at home sends us the enclosed cutting from a Canadian paper, thinking it might interest you to see how the sale of tea is being advertised in that part of America.—We are, dear sir, yours faithfully,
GEO. STEUART & Co.

[The advertisements referred to are headed "Genuine Diamonds and solid gold watches found in tea," and "One thousand dollars Reward." In these announcements the Traders Tea Company set forth that they "have completed their organization and have opened a store in Toronto at 15 King street west. Their tea is only sold in cans, price \$1 each. In order to introduce their choice blends of teas, this Company will put a souvenir in every can, such as solid gold and silver watches of the best American and Swiss makers. Also genuine emeralds, diamonds, pearls, turquoise, amethyst and sapphire jewelry set in solid gold, and various other articles of less value too numerous to mention. Bear in mind that this costly method of advertising will be discontinued after 60 days' time." A list of fortunate purchasers is then given. The second advertisement says that "One thousand dollars will be paid in cash to any charitable institution of Toronto that may be named by and reputable citizen who will prove that the watches sold in our cans of tea are not solid gold through and through, or that the diamonds are not genuine and set in solid gold, or the tea strictly pure and free from adulteration. The cry is still they come, and hundreds of patrons are made happy daily by receiving genuine diamonds and solid gold watches as souvenirs in their cans of choice tea at No. 15, King-street west. Remember that after 60 days these choice teas will be sold at the same price, same quality and quantity, but without these valuable holiday presents as souvenirs. The watches are genuine solid gold hunting case. American jewelled movements, stem-wind and set, and the diamonds are genuine and set in solid gold."—Ed. T. A.]

ROUGH ON TEA.

DEAR SIR,—What will your planting friends think of the suggestion of your London correspondent in his last letter, that they may shortly be supplied with tea boxes made of horse dung? This is surely rough on tea? Why it is worse than cedar! Your correspondent must hail from the land of the Houyhnhnms and Yahoos?—Yours truly,
E. B. CREAMY.

LONDON QUOTATIONS FOR FAIR PEKOE SOUCHONGS: ALLEGED DISCREPANCIES.

Colombo, March 13th.

DEAR SIR,—I should be glad to know what your weekly telegraphed quotation for Fair Pekoe Souchong is intended to represent.

You say "For such teas as Mariawatte, Diyagama and Kandapola," but on turning up the London broker's circular for the corresponding dates, there appears to be a discrepancy in price as will be seen by the following list of quotations:—

Telegram Published in <i>Ceylon Observer</i> .	London Broker's Circular.
Jan. 15th .. 10½d	Jan. 17th .. Mariawatte 9½d
" 22nd .. 10d	" .. Kandaloya 9½d
" 31st .. 9½d	" 24th .. Mariawatte 9½d
Feb. 5th .. 9½d	" 29th .. " 9½d
" 12th .. 9½d	" .. Kandaloya 9½d
" 19th .. 9½d	Feb. 7th .. Mariawatte 9½d
	" 14th .. " 9½d
	" .. Kandaloya 9½d
	" 21st .. " 8d

During the six weeks under notice I only find one quotation of Diyagama, and that is a small break and therefore no standard of market value. By an explanation of the above you will much oblige

ONE WHO DOES NOT UNDERSTAND.

[The above comparison surprises us very much, for we had only a few weeks ago to remark to our London Correspondents that we thought their market reports and quotations rather lower than Reuter's and other messages justified. We must now ask Messrs. Gow, Wilson & Stanton to look at the above figures and explain how discrepancies all the other way have occurred, or where the misconception comes in?—Ed. T. A.]

INDIAN TEA EXPORTS.

SIR,—According to your Calcutta telegram of 7th instant the total export "from Calcutta" to date *this season* to the United Kingdom, Australia, &c. is 102,000,000 lb. Are the words I have put in italics (from Calcutta) correct, or do the figures represent the exports from all India? Now that tea is falling so rapidly it is as well that we have the situation put clearly before us. Therefore in answering the above query would it be convenient for you to give your readers information as to what precise period "this season" referred to in your telegram actually refers—and at the same time give the figures for the preceding five seasons—and for the same period in each, of course.† If the figures for exports from India and Ceylon were computed from the same date, yearly it would be a great advantage, and of course the London figures for Imports, Deliveries and Stocks should commence from the same period. Then the figures would be of some value. All should commence 1st January and end 31st December in each year alike.

Messrs. Gow, Wilson & Stanton, in their circular of 27th December 1889, give imports of Indian teas into the United Kingdom for twelve months commencing June and ending May in each year say for

1887 ...	78,209,334 lb.
" 1888 ...	86,370,856 "
" 1889 ...	94,954,287 "

Now if the Indian season extends to end of May† we have still almost 3 months to run to complete season 1889-90, so that a large addition may yet have to go to the already large figures of 102,000,000 lb. referred to at the commencement of this letter.

What period does the Ceylon tea season now comprise? does it still begin 1st October and end 30th September? TEA PLANTER.

* From Calcutta, we believe.—Ed. T. A.

† We are unable to give our correspondent the figures for five years but the following show the exports of Indian tea from Calcutta for the past three seasons, from 1st May to 31st Jan., as given in the latest letter of the Secretary of the Indian Tea Association, Calcutta:—

1st May 1887 to 31st Jan. 1888...	82,463,713 lb.
Do 1888 do. 1889...	90,478,489 "
Do 1889 do. 1890...	93,829,219 "

Out of which were exported to Great Britain:—

1st May 1887 to 31st Jan. 1888...	79,437,936 lb.
Do 1888 do. 1889...	86,828,585 "
Do 1889 do. 1890...	89,129,802 "

From 1st Feb. to 7th March 1890, the exports were about 6 million lb. bringing the total up to 102 millions.—Ed. T. A.

‡ The Indian season runs from 1st May to 30th April, but very little is shipped during the last two months. The Ceylon season has just been changed to the calendar year.—Ed. T. A.

FINE CEYLON TEAS FOR RUSSIA.

Central Province, March 11th.

DEAR SIR,—Your leader in your issue of the 6th inst. how to open a market for Ceylon tea in Russia, is calculated to do much good at this juncture. The prices in London are wired lower and lower every week, and exchange being firm is also against us.

I do really hope the Ceylon Tea Fund Committee will push Dr. Duke's scheme at its meeting next week, and at once arrange to send a suitable agent to China to meet the Russian buyers. The Hankow market opens in the end of April and Foochow later on, so that there is no time for delaying decisive measures. It is quite impossible to send a sufficient number of agents through the length and breadth of Russia to make known the excellencies of Ceylon tea to a tea-drinking nation. Dr. Duke's scheme meets the difficulty in a comparatively inexpensive manner and with every probability of success. These Russian tea buyers in China practically control the whole of the Russian tea trade, and if our teas have the intrinsic qualities we are so fond of extolling, it is only necessary to bring them to the notice of these Russian experts in this simple and thoroughly practical manner and thus lay the foundation of a very large business with Russia direct.

Our best teas must only be brought to their notice by the agent to begin with, for if we are able to send our best teas where good tea is appreciated, the London market can take off our hands the commoner qualities through customers who only give us a penny more for broken pekoes than for pekoes.

If the Tea Fund Committee do not act promptly in this matter, many of the subscribers will give up faith in its power to push our Ceylon teas in countries where tea is now the favorite beverage.—Yours faithfully.

ONE LARGELY INTERESTED.

TEA BROKERS AND THE TEA TRADE.

SIR,—The following extract from a Planting Note may be fairly taken to represent the opinion of the planting infallibility, whose opinion on tea in general, and on nothing in particular, is frequently a source of amusement to the less favoured species of the sea-board capital and of the little town across the water.

Under the head Yatiyantota, 4th March, is written:—"I observe that tea prices, though somewhat better than at same period last year, are very far from satisfactory. Strange to say that brokers' reports seem at the same time to be unsatisfactory, and why is to me a mystery, because I believe it would be the same were I to forward breaks of the identically same quality, I would get a better report on tea shipped in say October and November than I would get on the same if shipped a month ago. I suppose it is that when prices are satisfactory brokers don't bother themselves picking out minor faults as they do when prices are otherwise."

The above note if properly expressed would read thus:—I believe that, brokers, tea tasters and the tea trade generally are a lot of consummate asses and don't know good tea when they see it. I believe that merchants, brokers, tea tasters, &c., &c., &c. (barring the V. A.'s) are a set of rogues and parasites. I believe that we are the men who know all things, that the sun, moon, earth, water, and particularly the railway, were created and made for our sole use and enjoyment, and that the Planters' Association is the Legislative Council of earth, or ought to be. Wonderful oh planter is your belief (particularly in yourself).

At his next Sunday tea fight it might be useful and instructive to consider the following points:—

1st. That prices are regulated by supply and demand.

2nd. That quality falls off at certain seasons of the year.

3rd. That as quantity increases and quality falls off prices fall too.

4th. That at present quality is poor, shipments are increasing: so prices are falling.—I am, sir,

Q. E. D.

**TEA, CONDEMNED AS UNFIT FOR FOOD,
DESTROYED BY HER MAJESTY'S
REVENUE OFFICERS.**

DEAR SIR,—In the interests of the English people, to say nothing of those engaged in India and Ceylon in producing the fragrant leaf as pure as it can be made, it is surely high time that some light were thrown upon the above important matter. The countries guilty of sending such poison to England for sale should now be named; for it would appear that neither seizures nor penalties nor present low prices have hitherto had any deterrent effect on these malpractices. This seems nor to be admitted on all hands, and if more proof were needed it is afforded by the recent utterances of the Chinese themselves. Just recently the *Shen Pao*, in a very long article addressed to those engaged in the Shanghai and Hankow Tea Trade, warns both growers and dealers of the consequences that will inevitably ensue if they persist in sending bad tea to England. It says:—

“In this last season the Chinese black teas were the worst that have ever been produced in the history of the tea trade. These teas are now unsealable in England and Russia. It behoves us, one and all, to try our best to remedy the evils that are killing the Chinese tea trade. This year will be their last chance: should the tea be as bad as it has been for the last three years, the trade in black tea with England will cease altogether. Five of the large English buyers in Hankow and Shanghai have gone out of the tea trade.”

Now these filthy Chinese teas when they reach England are to a very great extent mixed with India and Ceylon pure teas, but before this can be done they must pass, in their own packages, through the English Custom Houses, where the task of inspection should now be doubly vigilant. Something should be done at once to arrest the filthy stream of Chinese rubbish now being poured into the London market, for of course as the price descends the filth increases correspondingly, if not checked, indeed it threatens to injure the British Tea Enterprise. For some inscrutable reason, the British Government has decreed that the English people shall not be able to buy pure coffee, and now even tea is threatened!

If the Ceylon Association in London finds any obstacle placed in its way to obtaining the necessary figures, say for the past 10 years, separately, showing from what countries the condemned teas came, then Sir Roper Lethbridge will no doubt be able to bring pressure to bear. Taxpayers of 6d per lb. are clearly entitled to the information. To remove the duty altogether would be a great mistake, for the consumers of tea must, of course, bear the cost of these necessary safeguards. On the 7th February 1889 according to Messrs. Rucker & Benecraft's circular of that date there were 46 millions of lb. of China tea in stock in the London Bonded Warehouses. One wonders how much of this was pure (?) filth. With regard to the China congous, Rucker & Benecraft say these are of “really good quality and not the rubbish they were

formerly”—but this is in direct disagreement with the estimate of quality put forth by the Chinese *Shen Pao*, which says the quality is the worst ever sent to England?

ONE INTERESTED.

TEA IN JAPAN:—THE VICE-MINISTER OF AGRICULTURE AND COMMERCE ON TEA.—Mr. Mayeda, Vice-Minister of State for Agriculture and Commerce, appears to have addressed some very plain-spoken and pertinent remarks to representatives of the Tea-guilds, now assembled in Tokyo. He invited these gentlemen to the Department a few days ago, and told them, in effect that it rested with them entirely to push the tea trade. The cultivator, according to Mr. Mayeda, is the person whose exertions possess real value. If he is industrious, intelligent, and enlightened, the commerce in tea is quite safe to prosper. But instead of displaying these three qualities, he suffers his tea plants to deteriorate, and then when they cease to be profitable because their produce no longer tempts purchasers; he applies for official assistance or otherwise relies on others to help him. What he has to do is to help himself. The conditions of cultivation are just as favourable as they ever were, and the market is larger.—*Japan Weekly Mail*.

PROSPECTS OF PADDY AND COTTON CROPS IN THE MADRAS PRESIDENCY.—The report on the prospects of the late crops for the year 1889-90 is as follows:—

“Season.—As stated in the Report on the sowings of the late crops, the season was very unfavourable in several of the southern districts, and would have been most disastrous but for some good falls of rain in the latter half of December and the first fortnight of January which partially saved the crops and also helped recultivation in tracts where the crops had entirely failed. The following table shows the extent of sowings under each crop and its estimated outturn under the four divisions prescribed by the Government of India, a 20 anna crop being taken as equivalent to a full or bumper crop, a 16 anna crop an average one, an 8 anna crop a middling crop, and a 4 anna crop a bad crop:

Crops.	Extent of sowings in acres.		Percentage of the area on which the Crops are reported to be			
	Full.	Average.	Middling.	Bad.		
Paddy	3,743,000	7	37	36.5	19.5	
Cotton	1,387,000	4.3	44.2	38.3	13.2	

Paddy.—Out of a total of 3,743,000 acres shown against paddy 3,444,000 acres were returned by 14 districts. The probable outturn for the Presidency will be considerably below the average. In the four northern and in the ceded districts and Kurnool and the west-coast districts a fair yield is expected; but owing to the complete failure of the rains in October and November, the crop suffered severely over considerable areas in Nellore, Chingleput, North Arcot, South Arcot, and parts of Madura, Tinnevely, Salem and even Tanjore and Trichinopoly. Cotton.—The bulk of the cotton was raised in seven districts, which together contributed an area of 1,279,000 acres out of a total of 1,387,000 acres for the whole Presidency. The average yield is likely to be on the whole good in Belary, fair in Kistna, Cuddapah and Anantapur, but only middling or poor in the remaining districts. In Kistna and Cuddapah there was an increase in the area due to the great demand for cotton. There was an increase in area in Tennevely due to favourable early rains, but the outturn in this district as well as in Coimbatore was poor owing to the absence of timely rains.”

Kistna	163,000	Acres
Cuddapah	122,000	“
Bellary	271,000	“
Anantapur	121,000	“
Kurnool	246,000	“
Tinnevely	174,000	“
Coimbatore	182,000	“

Total... 1,279,000 Acres

BEE-KEEPING IN IRELAND.

The inquiries made in the preceding three years relative to the extent to which bee-keeping is followed in Ireland, and the degree of success attained in this special branch of rural economy, were repeated last year with reference to the season of 1888. According to the returns received in 1889 there would appear to have been a decrease of 7.4 per cent. in the number of swarms at work, and a decrease of 28.6 per cent. in the quantity of honey produced in 1888 as compared with the preceding year. There were 26,447 swarms at work in Ireland during the season 1888, of which 8,421 were located in the province of Leinster; 6,674 in Munster; 9,129 in Ulster; and 2,225 in Connaught. Of the 26,447 swarms, 9,145 were at work "in hives having movable frames," and 17,302 "in other hives." The quantity of honey produced was 328,092lb.; of this 94,887lb. were produced in the province of Leinster; 99,318lb. in Munster; 99,757lb. in Ulster; and 44,130lb. in Connaught. Of the 328,092lb., 148,441lb. were produced "in hives having movable frames," and 179,651lb. "in other hives." It was stated that 193,089lb. was "run honey," and 135,003lb. "section honey."

The average number of pounds of honey to each hive having a movable frame was, for the whole of Ireland, 16lb.; in Leinster 14lb.; in Munster 18lb.; in Ulster 15lb.; and in Connaught 26lb. The average number of lb. to each of the other hives was, for Ireland 10lb.; in Leinster 8lb.; in Munster 13lb.; in Ulster 9lb.; and in Connaught 16lb. The average quantity produced in all hives was, in the whole of Ireland 12lb.; in Leinster it was 10lb.; in Munster, 15lb.; in Ulster, 11lb.; and in Connaught, 20lb. The number of stocks brought through the winter of 1888-9 amounted to 21,486, of which 8,170 were in hives having movable frames and 13,316 in other hives. There were 7,751lb. of wax manufactured in 1888 of which 2,707lb. were from hives having movable frames and 5,044lb. from other hives. The returns received in 1888 gave the number of swarms at work during the season of 1887 as 28,569; the quantity of honey as 459 386lb.; the number of stocks brought through the winter of 1887-8 as 23,212; and the quantity of wax manufactured in 1887 as 9,725lb. *Globe.*

LEAF DISEASE AND COFFEE.

TO THE EDITOR, "SINGAPORE FREE PRESS."

SIR,—In a recent issue of your valuable paper I see that my old friend the *Ceylon Observer* says "It will be strange if the fungus which has ruined coffee in Ceylon and S. India is not deemed worthy even of mention in the Straits!" This is perfectly natural from the Ceylon standpoint:—especially when it is borne in mind that Liberian coffee which was introduced early in the seventies, is a more robust variety, and more able to resist disease, fell an easier victim to *Hemiteia Vastatrix* than Arabian coffee.

I am aware, Sir, that I am travelling on dangerous ground, and that where scientists such as Marshall-Ward and others have failed I cannot hope to succeed. Nor shall I attempt to do so. I merely desire to give expression to my individual opinion, which is derived from personal experience and observation. The origin of *Hemiteia Vastatrix* or leaf disease as it is more commonly called will in all probability remain a mystery, consequently the cure

of it may be looked on as problematical. The disease was first noticed in 1869, in the far-away district of Madulsima and rapidly spread over the Ceylon planting districts. Manure to stimulate the coffee was applied. Soils were analysed and treated according to prescription. Still the Coffee continued to weaken. Scientists were called in, and recommended "medicinal" cures; lime, sulphur, tar, and goodness knows what besides. All were tried without effect. Be it noted that before leaf-disease made an appearance, virtually the whole of the Central Province of Ceylon was under coffee. From Matale to Adam's Peak 40 miles as the crow flies N. to S., from Dolosbage to Teldeniya W. to E. nearly the same distance. In fact you may say that close on 1,600 square miles were under one cultivation. And in all this I doubt if one acre of jungle was left standing for 100 acres of coffee. Can it be wondered that disease appeared?

Complaints are made that the "slums" of our big towns in England are contaminated by overcrowding. May it not be so with vegetable cultivation? Is it not possible that an overcrowded vegetable population may be productive of disease, solely because all the atmospheric gases for one species which ought to be spread over a large area, are absorbed into a small one?

My belief is that if in Ceylon coffee had been planted in isolated patches, leaf disease would never have obtained the hold it has. And here in my opinion, (it is only an opinion), is our great safeguard—*coffee estates being so far from each other*. Moreover other cultivations, pepper, nutmegs, gambier, coconuts, &c., not to mention the ubiquitous lalang and an occasional piece of jungle intervening. I have hitherto seen no coffee affected with leaf disease, but I hope men with longer local experience than mine will give you their views.—I am, Sir, Your obedient servant,

W. TURING MACKENZIE.

STANLEY-WRIGHTSON TEA CHESTS FOR CEYLON.

My most recent letter told you of a first shipment of their tea chests to India having been made by the Stanley-Wrightson Syndicate during last week. It has been followed during this one by a consignment to Ceylon, and we shall all be desirous to hear how far the new boxes may be appreciated by your planters. We have been told that the price to be paid for the boxes is 2s 2d each, so that they will not cost more, if so much, as the wooden boxes in which shipment of tea is at present made, while a single experience will, it is believed, convince your planting community how largely it will gain owing to the increased number of chests that can be shipped to the ton measurement. It is doubtful; however, if the price charged will be sufficient to remunerate the manufacturers, though this cannot be decided one way or the other until the result of a longer time's experience may be known. But it is hoped that ere very long the supply of strawboard will be obtained locally and at a considerably cheaper rate than now has to be paid for it in Holland. There was a factory for its preparation from horse manure established some years back near Purfleet, but it was closed last year owing to its non-success. But those who worked it are now of opinion that the largely increasing demand for the article has established a better prospect for them, and already land has been purchased in the same neighbourhood—Purfleet—to erect a new factory upon. There is hope therefore that before very long the Stanley-Wrightson Syndicate may be able to obtain its material close at hand and at a reduction on its present cost which will obviate any necessity for increasing the price at which the first consignment of chests to Ceylon has been charged to its purchasers.—*London Correspondent.*

COFFEE IN THE STRAITS.

THE CHASSERIAU LAND AND PLANTING CO., LTD.—The report of the Chasseriau Land and Planting Co., (Ltd.) for 1889 shows great improvement on that of former years. Thus during 1888 the coffee deliveries amounted in value to \$5,892 only, whereas during 1889 they rose to \$23,796, and although the Company does not yet show any profit, it looks as if it might do so within the present year. Its progress, like that of nearly all Malaysian agricultural enterprises, has been hindered by an early underestimate of the capital required and an oversanguine estimate of the quickness of the returns. The expense in manuring seems now to be giving a reward, and if the present high price of coffee is maintained, the directors may expect to enter very soon on a period of debt reduction, after which they may expect to have a valuable property; and, if so, it will be the result of very patient and judicious nursing.—*Straits Times*, March 4th.

THE LONDON PRODUCE CLEARING HOUSE

The third ordinary general meeting of the shareholders in the London Produce Clearing House (Limited) was held on Monday at the City Terminus Hotel, Mr. F. J. Johnston presided, and in moving the adoption of the report observed that the principles of the company's business were now more generally understood and more fully appreciated, as was shown by the increasing volume of their contracts for coffee, sugar, and tea. In wheat and maize, their two latest introductions, the business so far had been insignificant, there having been apparently no reason for speculation in these articles. The prices of both were now so low as to preclude the probability of any serious decline, while, on the other hand, there had lately been nothing which seemed to justify any material rise. They must be contented therefore, to wait till circumstances changed, as they were likely to do shortly when the prospects of the new grain crops became the subject of keen observation and diversity of opinion. The business of the company was not to make speculation, but to regulate and keep it sound in the interests of legitimate trading, by which means they might be sure the most solid operators would be brought into the market. Fortunately they could afford to wait, as they had every reason to expect activity in several other directions, thus confirming what had before been said—that it would never do for a clearing-house to depend on only one or two articles, however large, if business was to be conducted with that economy which was so essential to the progress of trade. Their charges were now only 47 per cent. of their earnings, against 57 per cent. in their preceding accounts, a reduction which they hoped to see increased as their business developed. During the eight months under review their guarantee contracts had represented a value of £36,000,000, against something over £22,000,000 in the previous twelve months, or in the twenty months since the company began business a total of £58,000,000 of which all but about £60,000 had now been liquidated. No better proof of the soundness of their system could be given than the fact that in securing to the trade the due fulfilment of these contracts for £58,000,000, the loss of the company had been limited to £343. This result was the more striking when it was remembered that in both coffee and sugar there had been very large and sudden fluctuations in prices. With this almost entire absence of loss and so large a turnover, their earnings might seem small, more especially when it was mentioned that they had paid to the brokers about £50,000 in the eight months, or at the rate of £75,000 per annum, against about £30,000 in the previous twelve months. They had, however, laid it down as a principle that their tax on trade should be as light as possible, and that they must look to the magnitude of their operations as the surest and soundest means of securing to the shareholders a full and permanent return on their capital. The board were satisfied that

this policy was for the truest interests of the shareholders, as was also the directors' determination to make the company a vehicle only for sound speculation, so that the movement of prices there might rest on legitimate causes and not be made the sport of vicious manoeuvres. In short, their desire was to build up a system in every way worthy of the City of London, and one which would be of real use to commerce by giving our merchants a free and ready market, and thus bringing business to the port and increase its activity as a depot. Passengers moving from one part of England to another often found it much more convenient to take the longer route via London owing to its much better travelling facilities, and there was good reason to hope that foreign merchandise might do the same to a very considerable extent if London's great financial resources were assisted by a ready market, and provided, of course, trade were not hindered by prohibitory dock and labour charges. Mr. C. Czarников seconded the motion. A shareholder said that the return of 6 per cent. which was proposed was not what he had expected, especially from such a business and considering the amount paid to the brokers. The chairman, in reply, stated that they must make it the broker's interest to make business. The directors were confident that they were only at the beginning of the prosperity of the company. Meantime, he could not but consider that the dividend proposed was highly satisfactory for a new company. The report was adopted; and resolutions were afterwards passed declaring the dividend recommended—5s per share—and re-electing the retiring directors and auditor.—*H. and C. Mail*.

RUBBER DUTY.—One of the first acts of the new republican Governor of Pará was to impose a special tax of 20 reis per kilo on rubber entering that city for exportation, the product of which—estimated at 150,000\$ per annum—is to be paid to a "ring," or monopoly, composed of native merchants and known under the title of Companhia Mercantil do Pará. One object of this company is to obtain control of the rubber trade and then compel an advance of prices. This promised result is the "bait" held out to the governor and people of Pará and in swallowing it they appear to entirely overlook the fact that they are discriminating most unjustly against the foreign firms engaged in the rubber trade and directly aiding in the creation of a monopoly, under the management of a notorious local speculator, which will eventually cause incalculable harm to the trade.—*Rio News*, Jan. 13th.

MORTALITY AMONG CINCHONA TREES.—The Wynaad Planters' Association has brought to the notice of Government the great mortality of cinchona trees in the Malabar district, and requested Government to send scientific aid to discover the cause. The Association says:—"Opinion among planters differs considerably as to whether it is a specific disease that is attacking one plant, or whether the mortality arises from natural causes, consequent on the conditions of planting such as from unsuitability of soil or climate. But it is a fact that the mortality is on the increase, and this year young cinchona clearings in some parts of the district have died out wholesale. It is a question that we cannot determine for ourselves, and where the opinion of an expert would be invaluable. Government has before assisted the planting community under similar circumstances in sending Dr. G. Bidie to Ooorg to report on the ravages of the borer among coffee trees, and in Ceylon in investigating the nature of *Hemileia Vastatrix*, and we trust that in this instance Government will again come to our assistance, and send us the valuable scientific services, now at its disposal." The Government has directed Mr. Lawson, Government Botanist and Director of Cinchona Plantations, to proceed at once to the Wynaad, and make inquiries regarding the mortality referred to.—*M. Mail*.

NOTES ON PRODUCE AND FINANCE.

MR. GOSCHEN AND THE TEA DUTY—CHEAP CHINA TEAS AND THE "GROCER"—FAILURE OF JAVA COFFEE CROPS—A NEW JAVA COMPANY.

Mr. Goschen has given a private intimation that it will not be possible to introduce the Budget before Easter. As to the tea duty, it appears to have been positively stated within the last few days by one in some authority that in the opinion of Mr. Goschen reduction of the duty is not desirable; that at less than sixpence it would be more vexatious and less justifiable. Thus the prospect of the Budget is clouded with much uncertainty. The Cobden Club is advocating the abolition of the tea duty.

China teas are so extraordinarily cheap in Mincing Lane that the *Grocer* feels it its duty to urge the fact upon the trade, and to add that "as it is improbable that prices will remain as low as they are for any length of time, it behoves those who hold these views to look about them without much delay." "Indeed," says the *Grocer*, "already we find that it is impossible in some cases to duplicate the occasional extraordinarily cheap price of full first-crop teas, made as far back as two months. In black leaf teas, parcels of ripe, thorny Oopack are to be bought at 4½d., also full-flavoured Oonfa on the same level of price, and Ping-Kong, of the first crop growth, mellow and good, with a slight "tarry" flavour, at 4½d.—tea which used to be worth 9d. three years since. Again Kutoan at 4½d. to 6l., ripe and full in flavour, is a marvel of cheapness. Soomoo tea, which in the early part of the season was worth 9d., is now purchasable at 5d. for most useful-flavoured tea, eminently desirable in a mixture to soften down the roughness of Indian. Indeed no one could have anticipated that such value would be obtained as is now to be bought from 4½d. to 6d. For teas above this range of price, Panyongs from 6d. to 9d. show wonderful value; the latter being the price of tea worth 1s. 2d. earlier in the season. Rasping, full-flavoured, handsome Panyongs, full of point, are selling from 6½d. to 7d.; they are excellent drinking alone, and have such merit that they scarcely need any admixture of Indian or Ceylon. To those who can use Souchongs it is not too much to say that the prices for these probably eclipse all others in cheapness. Only 4½d. will buy a clean, useful Souchong, whilst 5½d. will bring a tea which grades between good and choice, such as last season sold as high as 1s. 4d. per lb." It is a sad reflection, and our contemporary makes the most of it, that "an examination of the red-leaf teas sold at auction lately discloses the fact that quite usable Soomoo brings 4½d. to 4¾d. only. It is needless to say most of these teas are selling for pence below cost, and several pence lower than the prices of last autumn. Those dealers and retailers who use scented tea will find an excellent opportunity of buying well a common grade at 5½d., or if they can give 7d. to 8d. they can purchase teas showing 2d. per lb. drop, or more, on the prices of two months back, and a grade of tea that of late years has rarely sold lower than 1s per lb and over frequently. 'New make' congous are attractive at their present low prices, and are perhaps more useful than any other kind of China tea, carrying as they do a dark liquor with a rasping Indian flavour; indeed, certain Hoyune teas possess grippy, telling waters, and they are eminently useful in a mixture. Some of the newly arrived fourth crop 'new make' have a full rich liquor, and make a delicious cup of tea. Supplies of this grade are quite short. Shipments have ceased from Canton, with a total crop only half the size of last season's, and thus buyers have no time to lose, as the above kinds will be very scarce long before new teas can arrive. They have practically all been sold on arrival, and virtually no stock is carried over. Good or choice black-leaf teas seem scarcely to exist, but some full-flavoured Keemuns are occasionally sold at auction at 9d. to 10d. showing a drop of 6d from opening prices. They are fragrant teas and very cheap."

Another, though a minor, feature in the market, the *Grocer* points out, is the small quantity of siftings that have arrived from China this year; the few lots auctioned going under 4d. Shantaam tea has ceased to come forward for some months, and the low-priced Oopacks at 4½d. must not be confounded with them. Buyers have an excellent opportunity (with China tea) of making up a remarkably good mixture showing a good profit to sell at 1s. 4d.; while such rich-flavoured teas as first-crop Keemuns and Panyongs, with the slight help of Darjeeling or Ceylon tea, would make an extraordinarily good article for sale at 1s 8d or 2s per lb. Green teas are selling very cheaply, having sustained a large drop on most kinds since last Christmas. The quantity of tea afloat from China is now very trifling, and, as far as it can be ascertained, it is as follows:—From Shanghai, congou, 500,000 lbs. weight; from Foochow, congou, 1,750,000 lbs.; and from Canton, congou, 250,000 lbs.

The failure of the Java coffee crop has been an unpleasant surprise in Holland. For more than two centuries the Dutch have derived large profits from coffee-growing in Java, and the average annual production in recent years has been over 140,000 tons. Blight is stated to be the cause of the present disaster.

A new company, with a capital of £208,000, has been formed in Amsterdam. It bears the name of Javasche Cultuurmaatschappij, and will promote coffee culture in, and trading with, Java.—*Home & Colonial Mail*.

COTTON IN INDIA.

The importance of cotton to the Indian cultivator seems to lie in the fact that neither the demand for it nor the selling price are dependent, to any appreciable extent, on the nature of the harvests in other producing countries, as in the case of wheat and oil-seeds. At no time since 1881 has the price of cotton varied by as much as three rupees per cwt. Formerly the shortness of the staple of Bengal cotton had always caused it to be more or less held in disrepute by English spinners, and consequently a percentage of it only was employed by them, for the sake of its comparative cheapness. This naturally caused the trade to be a rather precarious one, the demand and value being ruled by the production of America and Egypt. This has all changed, however, for in connection with the industry which has of late years sprung up in so-called cotton tweeds, union cloths, mixed cotton and woollen goods, &c., a special demand has arisen for the cotton grown in the N.-W. Provinces, its peculiar characteristics having been found specially adapted for use in the manufacture of these materials. The demand, too, is even more from the Continent than from England. A steady market therefore may be anticipated as long as the trade in these mixed fabrics lasts and the present standard of quality is maintained.—*Pioneer*, Feb. 8th.

PLANTING IN DELHI: TOBACCO.

The shipment of last year's tobacco crop has taken place unusually early, and most of the product will, in all likelihood, arrive at Amsterdam before May next. Railways and steamers have been hard put to it in meeting the demands of shippers. Up to the middle of this month, about 35,000 bales had been forwarded. Estate work on this year's crop goes on less actively. The Chinese new year began amid dry weather, but this favourable turn of events did not last long. From within two days after the beginning of the year, heavy rains have checked field labour. Burning operations have naturally stopped, and if a change for the better does not set in soon, this month also will close as disappointingly. March must turn out fine to admit of a satisfactory crop this year.

A correspondent assures the *Delhi Courant* that the rivalry of Ceylon tobacco has nothing formidable about it. The rainy nature of the climate of Ceylon stands in the way of effective competition. The rainfall in both colonies stands almost alike, but the number of rainy days differ widely. In Ceylon

sometimes as much rain falls in one day as during a fortnight in Deli. The deteriorating effect of these heavy downpours on the tobacco plants may be easily imagined. Still it is not safe to rate Ceylon too low as tobacco producer. Labour is so cheap and readily available there that the expense of cultivating the leaf comes to a mere nothing. Hence growers can make a profit at prices which would prove ruinous to Deli competitors.

In Deli itself, tobacco cultivation on the mountains has not turned out a success owing to lessened heat and greater moisture in the air. Scarcity of labour prevents utilising the mountain region for other produce articles more suitable to a colder climate. Tobacco still remains the only resource and standby of the planting community, who, under the circumstances, cannot help putting their eggs all in one basket.

A SUGARLESS WORLD.

A world without sugar can hardly seem a place worth living in to the juvenile mind. Farewell to jam in limited or unlimited allowances, to school-boy raids upon the pantry, to savoury puddings and dainty cakes, to lollipops, rhubarb tart and gooseberry fool! Blessings on the man who discovered the art of extracting sugar says the housewife who dare not contemplate the cuisine of a world literally without sugar. Blessings! reiterates the boy, with his mind dwelling on the preserve pots of Egypt. By his discovery he has diminished the sum total of wry faces among his fellow creatures. He has added a certain charm to the juvenile drug; at least, he robbed it of more than half its terrors. The aged crone of three generations ago who chewed her soaked tea-leaves, not knowing how to use them, must have longed, like Faust, for a new lease of life when she became initiated into the real luxury of the tea-pot, and the sweetening influence of sugar upon her new beverage. The raw school-miss, whose swollen cheek would suggest a bad attack of neuralgia, were it not that she has just paid a flying visit to the nearest confectioner's has reason also to bless him. And yet the world neither knows his name nor his native land. It is probable that he was some nude Indian or some lightly clad Chinese who lived hundreds of years before the march of Alexandria. But, whoever he was, he went with his painted face or his pigtail to his flaming pyre, or humble six feet of earth, "unwept, unhonored and unsung." Had he been a Greek, he would have been the theme of as many legends as Hercules; had he been a Roman Emperor, he would have been turned into a constellation or a god. Had he been an Englishman, he would have got £5 for his discovery, somebody else would have walked off with the profits of his inventions, and he himself would have been allowed to die of starvation. His epitaph might have been some bootless question in the House of Commons as to whether he had not a right to a memorial slab at least, if not a grave, in Westminster Abbey.

One might be sometimes tempted to wonder if Shakespeare ever really tasted sugar, were it not that he has a very few references to it. Most of them point to its sweetness. Chaucer also uses the word; so does the author of Piers Plowman. We do not know if it can be traced much farther back in English literature. One of the very earliest, if not the earliest known reference to it in connection with this country is made by a Venetian merchant who, in 1319 shipped 100,000 pounds of sugar which had

been brought from the Levant, and 10,000 pounds of sugar-candy to England to be exchanged for wool. This was about forty years before the dreaming Monk of the Malvern Hills had satirised in Pier's immortal vision*, the vices of his time. The English Crusaders made its acquaintance in Sicily, Crete and Syria, into the two former of which places at least, the Saracens had introduced the sugarcane. Then Venice, which had been importing a little sugar from the tenth century, became the centre of trade in the costly luxury, and remained the headquarters of such trade as there was until the Spaniards introduced the cane into the West Indies. It was by means of the tax which Charles V. levied on the sugar imported into Spain from San Domingo that he was enabled to build his palaces at Toledo and Madrid. All this means that except at a few favored points, sugar was utterly unknown all over Europe. Celt and Saxon, Englishman and Dane, Scandinavian and Norman, all had stormed their way into this little island of ours without ever having seen or heard of sugar. They had left their Aryan home before the sugarcane was first munched between Aryan teeth amid wah-wahs of delight and enjoyment by their Aryan brothers in the valley of the Ganges. They brought no name for sugar with them; the thing was unknown. The name does not seem to come into existence till that unknown man of genius to whom we have referred, discovered the art of squeezing the juice out of the cane and boiling it, and giving the product the name of sugar—that is "granules," or, as a scientific age would now say crystals: Not till after many ages did the names given to it by their remote brothers in the Gangetic valley come to the European peoples through the Persian and the Arabic—*shakar*, *sakkar*, *Anglice* sugar. In many parts of Scotland it is at this moment called *sukkur*. The earliest mention of sugar in the whole literature of Europe occurs in the year 320 B. C., when Theophrastus describes it as a honey extracted from canes or reeds. He had not heard of it as "granules," but as a syrup or juice merely. Strabo, on the authority of one of Alexander's Admirals, tells that certain reeds in India yielded honey without the aid of bees. Here again, Alexander's Admiral had only known of it as a syrup. Seneca had heard a story that honey was found in India on the leaves of reeds, but the story was quite wrong, as the juice does not exude naturally, but must be crushed out of the cane. Again, he also had heard only of the syrup. Pliny also had got hold of the wrong story—that it exuded as a gum—and he fancied that the gum hardened on the stalks into pale and brittle lumps—large "granules"—about the size of a hazel nut. This, however, was sugar-candy, not a naturally hardened exudation, but a work of art. The grand old man's discovery of boiling the juice of his sugarcanes had at last penetrated into the Greek and Roman world. What had the Greek housewife done all this time without it? If she had had it, would the Greek poets have sung of it in the same lofty strains in which they have immortalized the honey of Hymettus?

The only sweetener before the introduction of sugar was honey, and our Scandinavian fathers, like the Greeks, have embalmed its glories in legend and song. But unless bees were infinitely more numerous than they are now-a-days, honey also must have been a rare luxury. That it was a luxury is evident from our Teutonic word "honeymoon," which is derived from the custom

* The writer here commits a common mistake. The vision is that of *William*, the subject there being Piers the Plowman, i. e. Christ.—Ed. T. A.

of drinking diluted honey for thirty days after marriage. Honey, in any form, can hardly have been in daily use even among the great, or surely Attila would not have drunk so much hydromel on his marriage day as to die from the consequences. The mass of the European people may be said to have been utterly without a sweetener until the increasing use of tea and coffee in the eighteenth century gradually converted sugar also into an article of food. In 1700 the amount of sugar used in Great Britain was 10,000 tons, which was equal to an average of a little more than three pounds per head of the population per annum. This would give as much sugar per day to each inhabitant of England, Scotland and Wales as a person might lift with moderation between the forefinger and the thumb. What a wretched allowance! In a list which formed the food of agricultural laborers in 1765, given in the *London Magazine* for that year, neither sugar nor tea is mentioned; but in a similar list given by Sir F. Eden for 1796 both are allowed. It is obvious that most of the grandmothers of the somewhat elderly members of the present generation never had their childish fits of waywardness mollified by any preparation of sugar. A hundred years ago the article must only have been beginning to be known in the smaller towns of England and Scotland. In 1796, Sir F. Eden's year, when the little Carlyle was making his parents' nights wretched with the atrabilious squalling of his infantile genius, the enterprising grocer was, no doubt, still in the prime of his life, who first ventured to introduce it to the gossips of Ecclefechan. Burns, as a child, probably never tasted it; and when the little lame Wizard-boy of the North lay on his lonely hillside of the Scottish border, staring into the sun, with his childish brain already seething with the legends and romances of his native land, you might have travelled through all the villages from Galloway to Tweedmouth and asked for it almost in vain. So it was with gallant little Wales and the English Midlands. Could the ghosts of our great-grandmothers rise, not one of them would understand how it is that Sir W. Harcourt was lately making so much fuss about the Sugar Convention. Why, beet root sugar, which he has taken under his care, was only discovered a hundred and forty years ago, and nobody could extract it so as to make it pay until the beginning of the present century.—*Evening Standard*.

SOME BIG DIAMONDS.

The exhibition given by MM. Samson and Sandow at the Aquarium not long ago bore in many respects a curious resemblance to an incident that happened about five thousand years ago in Upper India. A numerous audience, as the reporters say, of chiefs and people had assembled to witness feats of strength and skill, the performers being the grandsons of a famous Maharaja. The Prince Arjuna especially distinguished himself; and when, after going through all his exercises, he prostrated himself at the feet of his tutor, the audience went into raptures of applause. But another athlete now appeared on the scene in the shape of a young warrior named Karna, who performed all Arjuna's feats and a few more besides. The Prince, like M. Samson, lost his temper and proposed a single combat on the spot. The rival champions were about to settle their differences in this way, when one of the Prince's backers discovered the fact that Karna was the son of a charioteer and beneath Arjuna's notice. Arjuna at once declined to fight, and, darkness coming on the performance ended. The story is told at length in the great Sanskrit epic; and it is this Karna who is com-

monly supposed to have been the original owner of the Koh-i-Noor, the splendid diamond now in possession of Her Majesty the Queen. The popular version of the Koh-i-Noor legend has been told by Sir Edwin Arnold. Karna was slain in the wars of the Mahabarata, and the diamond passed into other hands; "but death and distress always accompanied its lustrous beauty." After being transferred from one royal dynasty to another, the gem fell into the hands of a Raja of Central India; who, to quote the Emperor Babar's precise language, "was sent to Hell" by the first Mahomedan invaders of Hindustan. Babar tells us about the famous diamond, which was so precious, he says, that an expert valued it at half the money spent daily by all people on earth. He himself declined to receive the baleful stone, and made it over to his son, from whom it descended to the great Moghuls of India. Arunzebe's grandson wore it in his turban when he rode out to meet his conqueror, the Turkoman Nadir Shah. Nadir Shah caught sight of the flashing brilliant and cried, "We will be friends, and exchange turbans in token of friendship." It was Nadir Shah who invented the name Koh-i-Noor, "the mountain of light." One of his successors lost it to the Afghan Ahmed Shah, and still misfortune followed the stone. The last of the Durani Shahs surrendered it to Runjeet Singh, whose successors certainly had their share of ill luck. The first was poisoned. The next was wearing the gem when he was shot in open durbar. The third, Dhuleep Singh, surrendered the Koh-i-Noor to the English; and, as Sir Edwin Arnold grandiloquently remarks, "it shines now upon a proud and unstained forehead—above all others as the gem surpasses other gems in lustre—and secured from disaster by the simple charm of a good and noble life."

Such is the story related by Sir Edwin Arnold, and the same theory as to the origin of the Koh-i-Noor has been adopted by Mr. E. W. Streeter in his book about the great diamonds of the world, and by Professor Nicol in his article on diamonds in the "Encyclopædia Britannica." But according to Professor Valentine Ball, F. R. S., who has just brought out a learned and sumptuous edition of Tavernier's "Travels in India" (Macmillan), these eminent authorities are all wrong. He denies the identity of the Koh-i-Noor with the stone mentioned by Babar; and, instead of making it a gem which has brought death and distress to its owners for fifty centuries, he gives it a much shorter and less sensational history. In 1852, we must explain, Her Majesty allowed an Amsterdam diamond-cutter to recut the Koh-i-Noor. The work cost £8,000, and the money spent would hardly have been laid out more wastefully. The weight of the diamond was reduced by over 80 carats, and its distinctive character has been utterly destroyed. When the stone reached England it weighed 186½ carats; it now weighs only 106½ carats. Now, in 1665 Tavernier, the French traveller, saw a diamond at the Court of Aurunzebe which weighed, according to Professor Ball's reckoning, 268½ English carats. This is known as the Great Moghul's diamond; and Professor Ball's theory is, that it was the Great Moghul's diamond which Nadir Shah took to Persia, where it was cut down to the weight it had when sent to England (186½ carats) by one of Nadir's successors. His arguments are based on Tavernier's description and drawing of the stone, and on the fact that the Koh-i-Noor when brought to England showed two large cleavage planes, one of which had not even been polished and had distinctly been produced by fracture. On the other hand, Professor Ball is strongly of opinion that Babar's diamond is no other than the Dariya-i-Noor, the Ocean of Light, now in the treasury of His Majesty the Shah of Persia.

The history of the Great Moghul's diamond, identified by Professor Ball with the Koh-i-Noor, is far less sensational than the story told by Sir Edwin Arnold. It was found in the mine of Kollur "at seven days' journey eastward from Golconda, and was given in 1656, most likely less than hundred years after its discovery, to the Great Moghul, Shah Jehan, by Mir Jumla. In its rough state it weighed about 756 carats. It was afterwards cut by a Venetian named Hortensio Borgio, and reduced in weight to 268 $\frac{1}{8}$ carats. According to Professor Ball's theory, it was again cut in Persia to 186 $\frac{1}{2}$ carats, and in England to 106 $\frac{1}{8}$ carats.

Tavernier believed the Great Moghul's diamond to be the largest cut brilliant in the world. Next, in his opinion, came the Grand Duke of Tuscany's diamond; "but it is unfortunate," he says, "that its water tends towards the colour of citron." His commentator would identify this stone with "the Austrian yellow" now in possession of the Emperor of Austria, and valued at something between £40,000 and £156,000. Tavernier also saw in India a table-shaped diamond, with a flat surface about 2 $\frac{1}{2}$ in. long and over an inch broad. Its owners wanted £56,250 for it; and Tavernier seems to have thought it was quite worth the money. No one knows what has become of this beautiful stone; but Professor Ball tells us it has most likely been broken up. The same fate has doubtless overtaken a diamond of 155 $\frac{1}{2}$ carats, which Tavernier purchased at Ahmedabad for a friend.—*Pioneer*.

"T IS TEA."

(The Song of the Present in Ceylon.)

'T is tea, 't is tea, 't is tea, that makes Ceylon go on—
The dainty maiden, labour-laden, the highest hills she
climbs;
And well she stands, in many lands, beneath earth's
various climes,
And lowly still, with ready will, on sea-bound plain she
spreads;
Oh! she fills our isle with her flushing smile, but the cold
north wind she dreads;
'T is oh, oh, oh, for the fragrant flav'ry tea,
And ever may she grow and ever glorious be—
For 't is tea, tea, tea, that makes Ceylon go on!

For 't is tea, 't is tea, 't is tea, that makes Ceylon go on—
The Arabian berry once was king of our romance, but
now he's at his grave,
And no kindly hand can his weal command, no one his
life can save;
He's dying and he's dead, behold his haughty head
low boweth to the ground,
And lowly doth he languish in agony and anguish, for
see he is uncrowned!

'T is oh, oh, oh, for the coffee that must go,
But well for us yet, for we feel and we know
That 't is tea, tea, tea, that makes Ceylon go on!

'T is tea, 't is tea, 't is tea, that makes Ceylon go on—
The green green field that once would yield its wealth
of berries red,
It is doomed to the death, it breathes its last breath,
and soon it will be dead;
And sad, sad, sad, was the prospect that we had, when
first his death-knell rang,
But now a joyful peal in our spirit deep we feel, with a
gushing hopeful clang:

'T is oh, oh, oh, for the coffee that must go,
But well for us yet, for we feel and we know
That 't is tea, tea, tea, that makes Ceylon go on!

'T is tea, 't is tea, 't is tea, that makes Ceylon go on—
The princess tea our stay shall be, for us the hope hath
won,
And in our need a friend indeed, the good to us hath
done:

So on her we will wait and both early yet and late we'll
tend her with great care,
So may she thrive and grow, and vanquish every foe, so
we her wealth shall share:

'T is oh, oh, oh, for the fragrant flav'ry tea,
And ever may she grow and ever glorious be—
For 't is tea, tea, tea, that makes Ceylon go on!

ALFRED G. NICHOLAS.

Dikoya.

IRRIGATION WORKS IN THE HAMBANTOTA DISTRICT, CEYLON.

IRRIGATION—Walawe Works.—The large and important works connected with the Walawe irrigation system are now approaching completion. The huge anicut across the Walawe river at Liyangabaela, which was finished at the close of the year, looks a grand and imposing structure, well worthy of prominent notice in the history of the Province for the important part it is destined to play in the future well-being of the people. Its dimensions are fully described in a report furnished by the District Engineer in charge, and attached to my Administration Report for 187. Some additional work is necessary in the shape of wing walls below the anicut for the protection of the banks against erosion during heavy floods. Two masonry spill walls at Barawakumbuka are also required for the escape of cross streams. I had hoped that the close of the year would have witnessed the commencement of cultivation in the first open piece of ground below the head works, but the unexpected discovery of rock in three places has delayed the cutting of the main channel. This obstacle will however be overcome and the channel may be expected to be opened at an early date. With the exception of the rock cutting and the masonry work alluded to, the main channel has been completed as far as the Mamadala valley, where a block of about 3,000 acres is available for cultivation. The section to Ebtaluwa has yet to be cut to bring the water into the Kachobigal-ar valley. Subsidiary channels are now being traced down towards Tawaluwila and Ambalan-tota, which, when cut, will complete the whole scheme for the irrigation of 9,000 acres on the western side of the river. It is perhaps too soon to press for the irrigation of all the fine stretch of land on the eastern side of the river in Magam pattu, but it is bound to force itself on the attention of Government at no distant date, owing to the comparatively small expenditure required and the great demand for land that will arise when the scheme on the other side has been developed. The same anicut will divert the water, and the old channel is there in a fair state of preservation, only requiring to be deepened in some places.

The additional scheme of bringing water to the town of Hambantota by a branch channel from a point above Ridiyagama is also worthy of consideration, if only for the sake of furnishing the townspeople with a good supply of water. It will fill three tanks on the way—Ridiyagama, Koggala, Uda Beragama—and some natural depressions capable of being turned into paddy fields. One of the ideas in connection with this scheme was to fill the Karaganara salt lewaya with fresh water, and keep it so all through the year. The presence of a large body of fresh water near the town is no doubt commendable on hygienic principles, but it remains to be seen whether the water can be kept fresh.

The trace of the Hambantota channel has been completed up to a point near Hondawalpokuna within four miles of the town of Hambantota. Its distance so far is 32 miles, but I cannot help thinking, after referring to the plan, that a shorter way can yet be found, as the distance from the Walawe anicut to Hambantota in a straight line is not more than 15 miles. When nearing the town the trace ought to be carried along the ridge dividing the Karagan-ar from the Maha lewaya, so as to fill the fresh water ponds at the end of it.

Tissamaharama.—The cultivation under the irrigation works at Tissa was an undoubted success this year. Two crops were sown and reaped from an extent of 900 acres, producing 36,000 bushels of paddy. The extent cultivated for the present maha season is computed at 1,000 acres, the largest on record. The quality of the paddy is so good that producers find no difficulty in selling it at remunerative prices in Hambantota, Tangalla, and Matara to which towns it is almost all carted.

The three tanks referred to in my last report have already been so far repaired by the upkeep coolies as to enable a reserve supply of water to be stored in case the main tank runs short. Attention is now being directed to the restoration of another large tank

at the back of the Government bungalow, which it is hoped will be ready for use in a few months. As pointed out before, nothing but the restoration of the tanks which lie scattered about the place can raise Tissa to the high position it once occupied. It has already given evidence of development by the restoration of three minor ones, and by these means, as well as by the careful distribution of water, the cultivated area has risen in four years from 250 to 1,000 acres. To this must also be added the 500 acres in the vilages of Sitravila and Magama, making a total of 1,500 acres. Before Tissa sprang into existence Sitravila used to be cultivated once in five years when the rainfall was copious, while Magama was irrigated by a native amuna across the river kept up at the expenditure of much labour by the villagers. Both villages are now irrigated twice a year from the same source as Tissa. In the recent debate in the Legislative Council regarding the failure of irrigation works, Tissa was pointed out as an instance where a large sum had been sunk without an adequate return. This is scarcely correct, as no account has been apparently taken of the crop it produces, the direct gain to the District in placing a large supply of cheap and wholesome food within the reach of all, and a gain to the whole Province in providing a means of living to those who cannot obtain it in more crowded parts, while the improvements in the condition and appearance of people is most marked.

Among the improvements to the place are:—

(1) A new road from Tissa to Kirinda to supersede the old one, which in consequence of its low position was frequently under water. It takes a higher level and passes over the bund of three abandoned tanks. Its whole length of five miles has been cleared of jungle to a width of twenty-five feet, stumps rooted out, ground levelled, and a large swamp filled in at the Tissa end.

(2) The formation of paths through swamps and fields to connect different hamlets with each other.

(3) The restoration of the bunds of four small tanks for the storage of more water.

(4) The raising of the spill two feet by a kalinigula has so increased the supply of water that there is enough to irrigate a thousand acres over and above what is now cultivated, and applications to purchase more land have been frequently made lately. As stated before, there is abundance of surplus water from the fields flowing uselessly into the sea at present, but which ought to be utilised in the cultivation of more land.

(5) The restoration of the three tanks to the west of Tissa has rendered irrigable all the land above Yatala dagoba, as on the completion of the lowest tank the water when let out found its way freely from an old channel to the ground thereabouts. The inhabitants in the village of Sitravila below Tissa will be forced eventually to give up their fields, as from their low position in the bed of the Yoda tank it receives all the surplus water from the range above. An examination of the bund of Yodayawewa shows that with a very small outlay it can be restored to a good storage tank. There are two breaches which could be repaired by the prisoners, and the old stone sulice in the bund could be put in order again at a very small cost. The cultivators are not averse to an exchange for the new land outside the tank, so that the question of compensation is easily disposed of.

At the commencement of the year a new jail was established at Tissa with a force of thirty prisoners drafted from the Hambantota prison. The principal work they are employed on is the construction of the new road from Tissa to Kirinda, and they have, besides, attended to repairs on minor roads, small irrigation works, and the opening out of new paths.

Gonadeniya Scheme.—Another scheme which commends itself to the notice of the Irrigation Board is the revival of irrigation down the Gonadeniya-Alutwewa valley. There are fifteen tanks down this valley, of various sizes, with periodical cultivation under some of them. It is proposed to divert water from the Urubokka stream somewhere near Kaluwa above Udukiriwila tank, so as to fill the tanks twice a year. Gonadeniya tank lies at the head of the valley, and contains two springs, which with the aid of the water from the stream at one time, kept the tank full, but

years ago the bund was breached, and the bed has been converted into fields and gardens by the villagers, to which they have acquired a prescriptive right. I should leave this tank alone for the present, as compensation for lands would be heavy, but the water might be allowed to flow through it to those below, which were connected with each other by a channel, and traces of which are to be found here and there down the valley covered over with dense jungle. Two other schemes were laid before the Central Irrigation Board:—

(1) Converting Namuyaluwilla at the back of Tangalla into a large storage tank.

(2) Constructing anicuts at Ganewila on the Urubokka stream.

As, however, funds were short it was decided to let them stand over till next year for consideration.

The Netulpitiya Channel.—This channel, 2½ miles long, is designed, as stated in a previous report, to fill the tanks in the Netulpitiya valley with the surplus water from Udukiriwila tank, which itself is fed by the Urubokka stream. The heaviest cutting was at the lower end through a ridge to a depth of 80 feet with rock at the bottom. The work is almost completed now, and will be ready for use for the next yala crop.

The repair of the largest tank, Pattiyaipola, in the valley, breached in 1887 by an exceptionally heavy flood, is to be commenced at once, and sums have been voted for small improvements to the other tanks also in the same valley.

The importance of the channel cannot be underrated, for it will bring under regular cultivation once, if not twice, a year over 1,000 acres, which in former years never yielded a crop more than once in three years. There are five store tanks recently sluiced, and two more smaller ones, seven altogether, which ought to be filled regularly twice a year from the channel.

Kehelwatta Irrigation Scheme.—This is a scheme to bring under cultivation about 1,000 acres by throwing an anicut across the Urubokka stream and diverting the water by means of a channel to fields in the villages of Kehelwatta, Katuwana, Gomadia, and Karatota. A rough rubble anicut once stood in the place where it is now proposed to build a masonry one but being loosely put together was swept away years ago by a heavy flood. The old channel, however, is still there and wants clearing out—one section is still utilised to catch the drainage from the hills to irrigate a small tract. I have sent in my report on the scheme, and urged strongly that it should be taken up at once as it lies in the centre of a populous district which periodically suffers much from want. The people live principally on chena produce, and when this fails in times of drought there is great scarcity, as was the case at the close of this year, when I had to appeal to Government for money to open relief works. Rs. 1,000 was granted, and this is being spent in clearing out the old channel by village labour. A more recent examination of the ground shows that the building of an expensive anicut might possibly be dispensed with, and the cutting of a channel in the face of the rocky bank to a point higher up the river would answer equally well to conduct the water into the old channel. The condition of the people in the northern part of the Magam pattu claims the strongest sympathy of Government. The population is gradually dying out, and village after village is being deserted for the reason that the system of irrigation, which formerly enabled the inhabitants to raise enough food to subsist on, has through years of neglect fallen into decay. An examination of the country by me in September last showed that the water supply was formerly derived from the Diyagam pattu in the Badulla District. When the large works in the West and East Giruwa pattus have been completed an examination of this system ought to be commenced. If, as I hear, it is contemplated to restore some of the large irrigation works over the boundary in the Badulla District, something ought to be done to the tanks on this side to store the surplus water that must of necessity flow down, especially those in the Malalār valley, which were filled by the Malala stream, taking its rise in the Badulla District and passing through a series of

tanks down the valley, finds its outlet into the sea about eight miles east of Hambantota. At present it only runs for about three or four months in the north-east monsoon.

PROSPECTS OF TEA AND NEW OUTLETS.

A planter writes in praise of the "Russian" scheme, "or rather we may call it, the scheme to crimp Russian buyers from the enemy's camp! I do hope the P. A. and Tea Fund Committee may take it up at once and do the thing properly. The idea is a grand one, so feasible and at comparatively small expense too. Our man will meet more Russian buyers in a week than 10 commercial travellers would in six months, doing their "level best" in Russia. Besides Russian buyers, our man may meet men from all parts of the globe, and there and before them compare our teas with the best they can produce. The question of quantity will soon be overcome; once a demand sets in—see what we can do! Give us the price and you shall have any quantity. Why look at the fresh acreage coming into bearing every year! My fear is less we get outlets the prices will go down and remain there, and then Ceylon men may weep and wail and it's too late, too late to do much. The pity is, some good men stand aloof from the American scheme: what would be light for the many is heavy on the few! I'm glad you touched upon that subject."

GEMMING OPERATIONS IN RAKWANA.

March 11th.

There is little news in Ratnapura. The gemming syndicate are all concentrated at work in Rakwana. None of them have been so fortunate as to find a valuable gem yet, but large and valuable finds could hardly be expected out of a prospecting pit here and there. There is doubtless far more treasure in the gem lands of Sabragamuwa than has yet been unearthed, and which can only be realized through the agency of modern scientific appliances and British capital. A splendid new gem-yielding stratum has been discovered near Pelmadulla which has resulted in a lawsuit, and all the illian from a number of gem-pits has been sequestered by the Fiscal pending the decision of the District Court. One pit was dug by the landowners, 3 partners, on spec., resulting in finds of blue sapphires &c. to the value of R7,000. Of course a succession of pits were opened all along the line of watershed (which must be the bed of an old river), and the news flying to Ratnapura where a man who holds the lease of the said field for the purpose of cultivating paddy, so off he set to claim a share, which was refused. In consequence of this refusal he went to law.

SCRUB EXTERMINATOR.—The Madras Government consider it desirable to obtain an official expression of opinion from the Governments of Victoria and New South Wales regarding the utility of the chemical, before making any experiments in their Presidency on prickly pear, &c.

MR. A. C. CURTIS of Ting Ling, in his annual report says:—"I was further handicapped during the season, having run short of sirocco wood. This was due entirely to the misleading statistics given by Mr. Davidson, who estimates a maund of wood in fairly dry condition to a maund of tea, whereas I discovered from careful observation and the quantity of wood given out that the consumption of fuel was more like 2½ maunds to a maund of tea." We shall be glad to record the experience of planters in this respect.—*Indian Planters' Gazette.*

CEYLON TEA FOR RUSSIA.—We call attention to the advertisement of the Tea Fund Committee, following up the suggestion made in our columns. We trust the right man will be forthcoming for the mission. It was mentioned that he should be a good linguist and no doubt, a knowledge of French at least would be an advantage; but as nearly all Russian tea buyers speak English well, this is not so important as a good address, business qualifications and a thorough acquaintance with tea.

THE *Bulletin du Musée Commercial* says that it has now been proved by various experiments conducted by experts that the plant known as "alang-alang" (*Imperata arundinacea*) can be successfully used as material for the manufacture of paper. This plant grows in the Dutch Indies and the Malay Peninsula in boundless profusion, and requires no cultivation. Alang-alang under advantageous circumstances grows to the height of a metre and a half, and in most places farmers and planters are engaged in incessant efforts to keep it within bounds.—*H. & C. Mail.*

TEA ON OLD COFFEE LAND.—We are often asked the question as to whether tea grown on old coffee land is likely to "pay" in the face of low prices. The statement published for the old fields of Dambalagalla the other day partly answers the question; but from the other side of the country altogether we have an illustration given to us of 500 acres under tea most of it on land occupied by coffee previously for 40 years and yet the return for the past year equals 180,000 lb. made tea from fields 3 to 6½ years old covering the 500 acres. This tea (notwithstanding a substantial sum spent on artificial manure) has been put on board ship at 27 cents per lb., the average return being about 54 cents.

RAILWAY EXTENSION TO THE INDIAN TEA DISTRICTS.—We quote the following from the *Rangoon Times* for two reasons: (1) for the intrinsic interest of the news that the Railway is to be carried from Chittagong through Silhet and Cachar into the Assam tea districts; and (2) because the mode in which this line is to be made may well afford a precedent in the case of our own Northern lines. Of course in the absence of equivalent present traffic, the inducements in land-grants would have to be increased. Some may think it a pity that Government should alienate Crown lands in this way; but it were surely better to do so than to go on for another decade—a generation practically in Anglo-Colonial experience—without seeing a start made. Our news from Rangoon is as follows:—

The prospects of the port of Chittagong seem brightening. The new railway which is to start from that place to Dhubri will pass through Silhet and Cachar, and some of the most densely populated districts in India to the tea districts of Assam. A large part of the tea and jute which now goes to Calcutta will find its way to Chittagong instead. The concession for the line has been given to Sir Theodore Hope, the late Public Works Member of Council, who is to raise a capital of six crores of rupees for laying the line. No money guarantee is to be given, but the land for the rail is to be given free, as well as 5 square miles of land for every mile of rail laid, or 30,000 square miles in all; as well as the exclusive right to work coal and petroleum in a selected area of thirty square miles. It is believed that the Burma line may eventually be connected with this Chittagong-Assam line, but at what point is not yet known. We believe, Mr. Buyers, the Engineer-in-Chief of the Mu-Valley railway has had the offer of the Engineer-in-Chiefship of the Chittagong-Assam line, he having been Chief of the survey. He goes home next month however on eight months leave, and will very possibly return as Engineer-in-Chief of the Chittagong-Assam line. We have not heard who will succeed him in Burma.

GEM AND MINING PROSPECTS :

THE CEYLON GEM AND MINING SYNDICATE.

For some time back we have been receiving the latest and most authentic intelligence of the progress of this Syndicate in its work in Ceylon through the medium of our London Correspondent. We have no fault to find that it should be so—that in a very roundabout fashion, through the medium of a gentleman writing six thousand miles away, we should learn what is being done in a district sixty miles from Colombo. We had much rather that this should be the case, than that London Capitalists and others interested should suspect the Ceylon press of doing anything to inflate the cause of the several Gem and Mining Companies by maintaining a run of editorials or Special Correspondence giving currency probably to a good deal of inaccuracy and exaggeration mingled with the facts that might be picked up. Not that we have altogether neglected to encourage news letters from the Gemming districts or to chronicle the movements of the several experts and agencies at work. But it was quietly recognised by ourselves and others that nothing would better please the "experts" who had come out from England to report on our Mineral prospects, than to be "severely left alone" by editors and "specials." Well, they certainly so far cannot say that they have been badly treated by those "troublesome fellows of the press" in this Colony. It requires a very short acquaintance with Mr. Barrington Browne to see that he has studied to some purpose the golden character of "silence"—indeed one gentleman who ought to know considers that so far, this expert of high repute has been most reticent—that in fact he acts up in a high degree to Talleyrand's motto that "speech was given us to conceal our thoughts." Nevertheless, it is satisfactory to know, now that the term of Mr. Barrington Browne's mission is drawing to a close, that he has at least not been disappointed with Ceylon—that his mission was not an absolute mistake—and that some fruit at least may be anticipated to spring from it. His work in Sabaragamuwa will now, we learn, close in a few days and Mr. Barrington Browne hopes, we believe, to get away by the next Orient Company's boat—that would be by the S. S. "Orizaba" on Monday next. His Report to his principals in the London Syndicate is expected to prove a very full, indeed exhaustive and undoubtedly valuable document. Whatever be its purport—favourable or unfavourable to our widest anticipations,—the Report on a subject of so much interest to Ceylon must certainly prove equal to a State Paper of great value in the annals of the Colony. We must trust that it will prove the steppingstone to a regular "Geological and Mineralogical Survey of the Island." This is one of the first movements in advance which we must press on Governor Sir Arthur Havelock. It is very singular that such a Survey should have been so long delayed in view of the considerable and advancing importance of plumbago alone, apart from precious stones and the many other minerals of incidental interest and value. In Sir Wm. Gregory's time, such a survey was favourably considered by the Government and had Sir William only remained a few months longer at the helm than he did, a vote for a Geological Survey at least would have been included in the Supply Bill. We trust to see an even more extended Survey—to embrace Mineralogy and the use of a Diamond-boring Drill such as has proved

of great service in the Australian Colonies—provided for in our next Supply Bill and begun during 1891. No more desirable, useful or decidedly reproductive work can be connected with the administration of our new Governor.

Meantime, as we have said, we are hopeful that Mr. Barrington Browne's Report is not to be without results useful to the development of the Colony; but we cannot at all say whether certain sanguine anticipations current, will be realised. Possibly the outcome may disappoint a good many and prove satisfactory only to a few. But this much we may say on our own account and with a good deal of assurance, that the character of the results likely to arise for the benefit of the Colony depend to a very great extent on the Government. If the Ceylon Government as at present influenced, continues blind to its own interests—as representing those of the whole community—we may be very sure that only a minimum of English capital will be sent for investment in mining and gemming industries into this Colony. It is extremely doubtful in fact if Sir Arthur Gordon had published his draft Ordinance a few months earlier, whether we should have seen an expert out here at all. The promoters of the Syndicates and Limited Companies in Europe clearly went on the Mining Rules and Regulations as laid down by a previous Government, after special appeal and full consideration, in 1881. Why there should be a change at this time, unless the wish be to "choke off" European investments in Sabaragamuwa mines and gem pits, no one can make out. What makes the matter more aggravating is the general belief that the change of policy is not due to the "collective wisdom" of the Executive Council, to any motion on the part of the Legislature or any of its members, or to opinions expressed by experienced public servants of the Colony; but as is generally understood, to new-born zeal of comparative juniors who are credited with leading the head of the Government, in vulgar parlance "by the nose" in their desire to check, if not shut out European enterprise from local Gemming and Mining Industries.

SERICULTURE.—About 1,500 casuarina seedlings have already been planted on the acre of land at the Saidapet farm which has been selected for experiments in sericulture, and another 500 are being put down. The plants are thriving, and will probably by June next be fit for the silk worms to feed on. The election of the netting which is to cover the area is now being discussed, both as to the meshes which should be sufficiently small to protect the worms from wasps; and as to the material, which should stand the effects of the weather, Bengal twine, the material first selected, being found to decay very soon. The Hon. Mr. Garstin, who has taken much interest in the experiments, pays the farm bi-weekly visits.—*Madras Mail*, March 10th.

THE MORGAN CRUCIBLE Company (Limited) has just been registered in London by Davidson & Morris, 40 and 42 Queen Victoria Street, E.C., with a capital of 300,000*l* in 20,000 preference shares of 10*l* and 1,000 ordinary shares of 100*l* each. The object of the company is to acquire and take over as a going concern the businesses of crucible manufacturers, potters, and manufacturers of plumbago, belonging to and carried on by the Morgan Crucible Company, in accordance with an agreement, made on February 26th, between W. V. Morgan, Walter Morgan, Septimus Morgan, Octavius Morgan, E. V. Morgan, S. A. Peto, and A. R. Harding of the one part, and Ernest M. Morris, on behalf of the company, of the other part.—*E. Mail*, March 7th.

LETTERS FROM JAMAICA.—No. 31.

WEATHER AND CROPS IN 1889—LABOUR SUPPLY—THE FORTHCOMING JAMAICA EXHIBITION—THE LOCAL LEGISLATURE PASSING 23 LAWS IN AS MANY DAYS—ST. LUCIA TO BECOME THE PRINCIPAL NAVAL STATION OF THE WEST INDIES—MR. ESPEUT AND THE RAT PLAGUE—THE MONGOOSE, BECOME AN EVIL IN PLACE OF FRIEND! ENEMY—GUATEMALA: THE CITY AND COFFEE DISTRICTS—COFFEE CULTIVATION, LABOUR SUPPLY AND TRANSPORT—ROADS—GERMANS, THE LARGEST PROPRIETORS—POLITICAL WARS—RELIGION AND SUPERSTITION OF THE NATIVES—FOOD SUPPLY AND TRAVELLING ACCOMMODATION.

Blue Mountain District, Jamaica.

For packet of January 29th.

It is quite three months since I had this pleasure, dearth of matter must be my excuse. As in Ceylon, so in Jamaica, will 1889 be notable as one of the rainiest years on record. Fortunately there were no heavy floods, and the rain was more evenly distributed than is usual; fine days were few and far between. The above state of things no doubt benefited our "settlers," both as regards their coffee patches and provision grounds, so that with coffee selling at high prices, and a plentiful supply of yams, our friends Mr. and Mrs. Quashie have had no inducement to come and "give Massa a little assistance," as it has sometimes been said to me.

Labour is truly with us very precarious; the old Ceylon planter sadly misses his regular force of coolies working from Monday to Saturday, and, barring very bad weather, he can pretty well see his way to getting his work regularly and properly done; here in Jamaica we must be content to have patience and wait for the labour, when it suits our neighbours (for none reside on the estate) to come and work for us.

Crops in the high districts will not as a rule be large, for the rain quite spoils the chance of good blossoms: I have only heard of two or three properties where a good yield is expected: we must therefore hope that in 1890 seasons will be more propitious, so that we may look for a good paying yield for the 1890-91 crop.

The chief topic of interest at present is the Jamaica Exhibition, which is fixed to be opened in January 1891. The buildings are to be erected on a piece of land 12 acres in extent, just above the racecourse and within easy reach of Kingston; the grounds will be nicely laid out. As regards guarantee, upwards of £23,000 has been promised, and the matter seems to have been very warmly taken up in London. Jamaica has not much to show except local products; and hardly any manufactures; so very much depends upon what will be sent from abroad, and whether it will draw Americans, and other "strangers," to the island. Of our own population, but a small portion can be expected to attend, as distance, lack of cheap transport, and want of the needful funds will prevent very many from attending Kingston. It will therefore be very fortunate if the Exhibition when closed does not leave a debt to be made good by the guarantors; but even if it does, the good the Exhibition must do indirectly to Jamaica will be full compensation for any expense incurred by its inhabitants. Of course there are to be amusements as well as the Exhibition pure and simple: a small aquarium has been suggested, and a local native village, after the manner of the Paris Exhibition.

Our local Legislature surpassed itself by passing 23 laws in almost as many days amongst others

"the Mountain and River Reserve Law" has not found favour amongst the planters and settlers, and will it is hoped be amended next session.

General Pearson of *Ekwave* fame, the present Commander-in-Chief of the West Indies line of service, will be up next April, when the Head-quarters are to be moved to Jamaica, and St. Lucia will become the principal Naval Station and port of call for the Royal Mail Steamers, whence the branch lines will radiate to the other islands. St. Lucia has a magnificent harbour, but unfortunately the island is notorious for the deadly snake the "Fer de Lance"; and it is hoped some means may be found of exterminating them. In Jamaica Mr. Espeut who introduced the mongoose has won for himself the name of "Espeut Batta" from the natives: the object, that of stamping out the rats which played havoc with the sugarcanes, was an excellent and laudable one, and I believe answered at first, but "Massa Mongoose" proved fastidious as time grew on, he killed off the snakes and lizards, and then proceeded to eat up the eggs of all the ground birds, now he robs hen roosts of eggs and chickens, and eats bananas, and other "sweet stuff," so unfortunately the rat once more flourishes in the sugar and coffee fields, and the insect-eating birds having also almost died out. The ticks on which they fed have become so terribly bad on cattle-pens that legislation must soon be brought in to rid the island of them and of the mongoose, he now proving himself no longer a friend but a most mischievous enemy.

Since I wrote my last letter I have met a friend who has lately travelled in Guatemala, and as some of the information I derived from him is sure to be interesting to your readers, especially my brother planters, I propose ending up my letter therewith:—

GUATEMALA as generally known is the most Northern of the Central American Republics, and produces an excellent quality of coffee. It is best reached from Jamaica, *via* Livingston, the port on the Caribbean Sea: my friend went by that route, travelling across country to the capital, thence he went north to Coban, the principal coffee district, and returned to Livingston by the route made use of by the planters for the despatch of their coffee to the seaboard. My friend's chief desire to visit the country was to see for himself some of the ancient ruins for which Guatemala is celebrated, and in this he was in great measure successful; he also went north to visit the Coban coffee district: this naturally was the subject upon which I was most anxious to obtain information.

GUATEMALA CITY is situated at 4,850 feet above the sea, the climate is therefore very pleasant and healthy; the adjacent peaks of Agua and Fugo both volcanic are 13,400 and 12,000 feet in height, and tower above the plateau, and render the scenery very fine and grand.

COFFEE DISTRICTS.—There are two—Costa Cuca in the south, and Coban in the north, the former was visited by my friend and is evidently the best of the two.

THE COFFEE is magnificent, is allowed to grow native fashion, and is picked from portable ladders: 8 cwt. an acre, is considered a fair crop, but most often is largely exceeded. When a property gets down to 5 cwt. an acre it is abandoned and fresh land is opened, of which there still appears to be any extent, it is marvelously rich in soil, and lies on a very gradual slope. Cultivation except in one or two instances does not appear to be kept up, as in Ceylon.

LABOUR.—The grants of land obtainable from Government are generally found to contain settlers

resident upon them. On purchase of the land, these settlers are by law or custom bound to work for the owner; other labour is also procurable by application to Government, who requisitions it from the heads of the districts. The labourers are mainly the native Indians of the Red Indian type, in some instances more or less mixed with Spanish blood.

TRANSPORT is at present the greatest difficulty to the country. There is one railway, 76 miles in length, from Guatemala to San José, on the Pacific coast, and it is to be extended to Coban and no doubt eventually to the coast on the eastern or Caribbean side of the Republic. When the latter is completed it will be an immense saving and obviate the Cape Horn route by which much of the produce of the country has still to be transmitted. At present the cost of sending the coffee from Coban to Livingston exceeds the freight to Europe. The distance is 200 miles, and is traversed partly by road, by lake and river; first for about 90 punzos, by carts and mules; then down the river Polochis to Yzabal, where it is transferred to large stern-wheel boats, and taken to Livingston; it has thus to be shipped three times. The coffee is packed in bags lined with waterproof paper. Some coffee is now being sent to London in parchment to be there finally cured. Most of the Nicaragua coffee goes to Bremen, via New York. Some is also sent to London, and the coffee from the southern districts finds its way to Europe round Cape Horn, San José being the port of shipment.

ROADS are bad, especially on the eastern slope; they are not macadamized.

PROPRIETORS are mostly Germans; there are some other foreigners and Americans but very few English in the country. The two largest plantations are owned by German companies, are each from 1,500 to 2,000 acres in extent, one is named "Los Mercedes" the other "El Provenir." The machinery is chiefly of German manufacture, the pulpers are on the disc principle.

POLITICALLY the country has of late years been disturbed, and there was war with Salvador: the late President was killed in battle, and was succeeded by the Vice-President, General Barraundia who attempted to seize the Government, but having been defeated was exiled the country.

There are wild animals, but not so bad as farther south.

The natives are nominally Roman Catholics, but are still very superstitious. The food of the country is by no means tempting, it consists chiefly of tortillas and frijoles, corn cakes and small black beans. The accommodation for travellers is very bad, and one has to carry a hammock, as there are generally no beds in the resthouses, and one must also take tinned provisions, as the native food is very coarse; bread cannot be got away from the towns.

As to Central America generally, when the railways and canals are completed to the west coast it must become even more a rival than it is at present to the Brazils and the West Indies as a coffee-producing country. Much however, must depend upon a sufficient supply of labour at a moderate cost.

W. S.

COCONUT BUTTER.—Veyangoda, March 11th.—Everybody interested in coconut cultivation cannot but be glad that new uses are being found for the nuts. I hear that a butter manufactory is being started in Colombo by a Syndicote. The supply of nuts on this side of the country is by no means equal to the demand, and as a consequence we have very fair prices.—*Cor.*, local "Examiner."

AGRICULTURE &c., IN THE SOUTH-EASTERN DIVISION OF CEYLON.

HIS EXCELLENCY AMONG THE VEDDAS—CAMP NEAR FRIAR'S HOOD—DRIVING THROUGH THE MOORISH VILLAGES—JUNGLE LAND UNDER CULTIVATION—IRRIGATION—VISITING THE FOUR GREAT ANICUTS—FAILURE OF THE N. E. MONSOON—VISITING "VISARAI"—DEMONSTRATIONS OF WELCOME—AT TIRUKKOVIL—ARUGAM BAY TIMBER—MAGULMALA VIHARAI—VISIT TO THE "CHIMNEY HILL"—WANT OF IMPROVED COMMUNICATION—JOURNEY SOUTH.

As already announced in our columns, His Excellency entered the Eastern Province travelling from Badulla via Nilgala, which is now one of the few localities where genuine Veddas are to be found. Thence His Excellency proceeded by the old Badulla Road to Mandur, as far as Kandikkaddu where the camp was pitched near the bund of that great tank and under the picturesque heights of Kampudimalai and not far from where the "Friar's Hood" rears its "turbaned head" (Tpparan Kaddimalai—Turban-tied hill—is the Tamil name for this mountain). Here the route went across country via Wiragoda tank, completed last year, to Chadaiyantalawa tank, where it joined the recently made gravelled road which both the Agents of this and the adjoining Province desire to see extended via Nilgala to Bibile (on the Badulla-Batticaloa road), thus giving the populous and highly cultivated South Batticaloa district direct and easy access to the Uva markets for their produce.

The doings at Kalmunai have also been fully recorded in our columns, and we need only add that on the morning of the 24th His Excellency and party started for Irakkamam, driving through Kalmunai, Kudiyruppu and Sanchamarutu, large Moorish villages which were all en fete, the roads lined with gaily dressed crowds and His Excellency graciously stayed a few minutes at each of the pandals where he was freely sprinkled with rosewater and presented with innumerable limes (the usual mark of respect in this country and a reminiscence of the old custom which forbade appearance before a superior emptyhanded). Proceeding via Arasadi, His Excellency had every opportunity of appreciating the industry and energy of the population which has brought over 25,000 acres of jungle land in this part of the district under the cultivation of paddy within the last third of a century and who are still clamorous for further extensions if only corresponding facilities for irrigation are provided. These facts surely justify the foresight of the late Mr. Woodford Birch, whose efforts it may be remembered were opposed at the time by an influential section of the community, even as those of others have been since decried both here and elsewhere; but let us hope that the grand success at Batticaloa may teach those impatient of success and discouraged by the want of immediate returns, the necessity of allowing sufficient time for "irrigation to pay."

At Senkappadai, His Excellency visited the four great anicuts on the branches of the Pattippalai Ar which admit of its water being diverted in numerous directions as the exigencies of cultivation require. Above these anicuts are situated the great tanks of Ambarai and Irakkamam with a spread of 3,000 acres which are filled from the river when in flood and the impounded waters stored for distribution during the long dry season which prevails on this side of the island from February to October. Unfortunately the failure of the N. E. monsoon this year has prevented the tanks being filled as usual, so that when the Governor arrived at Irakkamam His Excellency found that tank had only about $\frac{1}{4}$ of its usual contents at this season of the year. Ambarai too is in a similar

plight and unless heavy and unusual floods come down the rivers from the Uva hills, there must inevitably be a very limited cultivation for the kalavellamai crop and consequently it is feared much distress from the "famine of work" amongst the large population, which is almost entirely dependent on paddy cultivation. Such an abnormal season is extremely rare and has certainly not occurred since 158.

Near Irakkamam His Excellency visited the old Buddhistical ruins locally known as "Vihara," where a very fine brick dagoba covered with heavy jungle still exists, but most of the stonework described in former accounts was found to have been utilized in the construction of the anicuts in the neighbourhood. In the afternoon of the same day His Excellency and party rode through picturesque and park-like country for some seven miles to the Tillai Ar. This river was too deep to ride through, so the Vanniva had provided boats to cross it and on the eastern bank His Excellency was welcomed to the populous village of Karunkodditivu by several thousands of Moormen of the Akkarai Pattu with firing of guns, presentation of limes, native music and other demonstrations of welcome: and when passing through the village was saluted by bodies of Moormen standing inside their fences with the "kuravai," a vibrating sound made by placing one finger within the lips and agitating it so as to act on a low and rather monotonous vocal chord which proceeds from the performers' mouths. This is considered a very high compliment and reserved for special occasions like the present.

Next day His Excellency proceeded to Tirukkivil, where there is a resthouse pleasantly situated on the seaside and a very celebrated Hindu temple, to which there is a large annual pilgrimage in the autumn of each year. Sagamam was the next halting place where there is a large tank to which it is intended to make additions and extensions at an early date for the benefit of the 2,000 acres dependent there. At Tirukkivil the limit of the populous part of the district was left behind and South of this the villages are few and far between. At one of these Kumariya 10 miles south of Tirukkivil, His Excellency was met by the Ratemahatmaya of the Sinhalese Pattu of Panawa, where stay was made for a night. Next day the route lay by Rotte-wewa (a tank restored during His Excellency's administration and which provides for the regular cultivation of nearly 1,000 acres) to Potuvil, which is a large village with a population of over 1,000 persons, a large portion of whom are Moors, enterprising cultivators and traders. Close by is Arugam Bay, a very safe anchorage nearly the whole year round, where a considerable quantity of timber chiefly halmililla is shipped some to Colombo and some to Southern India as well as some paddy of which more is produced than can be locally consumed. It is proposed to continue the Monaragala Road already completed from Wellawaya to Munane, so as to reach the sea at Potuvil where the Badulla timber can be shipped to a market at Arugam Bay. After this His Excellency made a diversion from the Coast Road for the purpose of visiting other recently restored tanks at Lahugalla and Naula, in the course of which His Excellency visited Magulmaha Vihara, a little known but interesting Buddhistical remains where was seen a small dagoba with standing in a platform bounded by a worked stone wall in a capital state of preservation. There are also other numerous remains of stone work in the jungle all round. Mr. Nevill is said to have visited the locality, but it is not known if he has published any account of the ruins. After breakfasting at the small village of Panawa,

His Excellency reached Okanda, 85 miles south of Batticaloa, on Saturday evening, where Sunday was spent. A visit was paid to "Chimney Hill," a well-known landmark on this coast, from the top of which a beautiful panoramic view was obtained of the country for many miles round—extending from Namunakula to the Kataragama hills and the Basses Lighthouse. Okanda is the site of a celebrated Hindu temple, which is visited annually by a considerable number of pilgrims on their way to and from Kataragama. The "temple" is a poor building and its attractions are restricted to the odour of sanctity which tradition has attached to it: the only resident is the kurukkal of the temple and the ordinary accommodation for the travellers was a wretched shed. A suitable camp had been provided for the accommodation of His Excellency and party under the shade of some fine trees which stand close to the celebrated rock in the fissures of which an ample supply of good drinking water is available all the year round, sufficient for the "resident population," as well as visitors in the season. Timber is also shipped here for Colombo and Madras, and there is almost an inexhaustible supply in the "back country" in the Badulla district which only requires improved communications to be made readily accessible for export at this point. Possibly a wooden tramway such as has been used in the Malay Peninsula would be as cheap a way of securing this as any.

On Monday, the 3rd, Kumariya was reached, where there is a small village of some 50 persons, all told, and which is really the only inhabited spot between Panawa and Kirinda, a distance of over 60 miles. Here His Excellency met by Mr. Short and next day left for Pattanai en route to Kirinda, Mr. Elliott taking his leave at the Kumbukkanar, the boundary of his Province, 98 miles south of his head-quarters at Batticaloa.

At Tirukkivil the gravel road ends for the present, but funds have been provided for extension southward of the coast road, and it is hoped that during the course of next two years it will be possible to drive to Potuvil. His Excellency's route was consequently south of this along a jungle track lying for the most part along the margin of the numerous "mukattuvarams," twenty-one of which are studded along the coast between Karunkodditivu and Kumbukkanar. These are referred to by Tennent as the "Gobbs" which are the special feature of the east coast of Ceylon and which add to the difficulties of roadmaking in this part of the island. They usually form the haunts of innumerable aquatic birds of which however there are this year comparatively few, owing it is believed to the failure of the monsoon, in consequence of which these lakes now contain only salt water instead of fresh as usual at this season. The sporting members of the party, however, under the genial guidance of the Uva Agent obtained a fair share of amusement and opportunities of seeing the larger game in their own homes, though not equally successful in obtaining tangible trophies of their reminiscences.

A HOME IN THE NILGIRIS: COFFEE.

"D" writes from Coonoor to the *Englishman*:—
The *on dit* is that at last we are to have the railway from Mettappoliam to Coonoor. This will no doubt be a great boon to the inhabitants, as all supplies, in the shape of grain, oilman's stores, etc., will be brought up at a less cost than it now is, and invalids, delicate ladies, and children, will avoid the jolting and discomfort of the

tonga. The poor long-suffering horses too will undergo a change of life. Let us hope for the better. In my last I spoke of the tea industry of these hills. I will now say something about coffee. Coffee planting has been carried on for the last 50 years, I am told, but was commenced only on a small scale by Messrs. Lascelles and Cockburn, and the late Mr. James Stanes. During the last 30 years, however, it has become a most important and profitable industry. Outlying districts which at one time were inaccessible, have been opened up by European enterprise.

The first estate I visited was the Hill Grove, one of the finest in the neighbourhood of Coonoor, comprising about 300 acres, and I was most cordially received by the veteran proprietor, who informed me that he expected this year (1890) to pick between 60 and 70 tons, which, at the present price of coffee in the London market, viz., £1'0, ought to give him a good return on what he values the estate at, three lacs of rupees, representing, at the rate of exchange, in English money about £21 000. Mr. R. who owns Hill Grove was one of the pioneers of planting up here. He came to the Nilgiris a poor man, but by his industry, perseverance and honesty is now the owner of several large estates and houses. I have heard him spoken of as always being willing to help the poor and needy. Although considerably advanced in age, Mr. R. walked about with me explaining everything connected with the establishments as if he were in the full vigour of manhood. I had not time to visit the whole property, as there were some steep descents, and I was just afraid my pony would not be able to climb back, but I came away impressed with the idea that Hill Grove was a nice little bank where one could draw cheques for decent sums when required.

My next excursion was with Mr. Thos. Stanes, whom I spoke of in my last as the proprietor of the Glendale tea estate. He writes me to ride out and visit his two outlying estates, some 12 to 13 miles off.

We leave Coonoor in the morning and drive to Glendale, where we have sent our ponies on, and after taking luncheon with the manager we mount our nags and ride through a most lovely country. The first property we visit is the Colacambay coffee estate, and I do not think I have seen any place in the world that could come up to it in scenery. Sometimes we are going through the tracks of rich and wooded land held in reserve by Government, and at other times through private estates chiefly planted out with coffee, tea, and cinchona (the latter now a neglected industry, only fetching a few pence per pound in the London market, a few years back it brought as many shillings.) We ride past fine undulating land, which, if planted out with some good Australian grass, would no doubt make excellent grazing ground for a breeding stud. We arrive at the Colacambay estate towards evening, where we are most cordially received by Mr. Beaver, the manager, and we are offered hospitality for the night by the lady of the house—a most roomy and pretty bungalow built on a hill some distance from the cool lines. Below the hill the surrounding grounds put one in mind of a gentleman's park in England with its enclosed fields for grazing cattle, and having a couple of well-finished tennis courts. The hill commands a fine view of the property, with the Bavania river and plains below. To the north-east may be seen the fine waterfalls from which the estate takes its name. The Shevaroy and Annamulle Hills are also visible on a clear day. There is a good cart road *via* Kartairy which connects Cola-

cambay with the Coonoor Ghaut, and there is a bridle path across the mountains to the latter town. I had no idea a coffee estate could be so picturesque. Colacambay consists of three or four ravines with a good cart road running round at the top, the pulping house and store are at the bottom. The assistant's bungalow and cooly lines are erected at the head of the estate. I may now mention that a Government Post Office and Savings Bank are also established on the estate's land, so that the neighbouring planters enjoy the comfort of a daily paper and one delivery of letters per diem. One finds it hard to describe properly such a place, but the reader can imagine well cut paths winding through luxuriant fields of coffee, the former leading to the buildings. Coffee planting at an elevation like that of Colacambay must be essentially a healthy and pleasant life. There are 200 acres under coffee, and the remaining land is kept for grazing; and in connection with this I saw a magnificent cattle shed 150 feet long where some 250 heads are penned every night. Manure of course is the chief item in coffee planting; but I am told it is one of the most difficult things to get in quantities sufficient to manure a third of an estate yearly, so that planters have to fall back on patent manures, such as bone and poonac, etc.

A few words as to how the coffee bean is cured may interest. Large gangs are sent out to pick the ripe fruit. In the evening the quantity picked is measured, after which it is passed through a machine called a pulper. This separates the pulp and skin from the bean; the latter passes into vats, where it remains till sufficiently fermented. It is then thoroughly washed, dried for some days, and despatched to the low country, where it is further treated by what is known as garbling, *i.e.*, the parchment and skin on the bean is knocked off, and the beans are sorted into their different classes, put into casks and shipped Home.

Having passed a most pleasant evening with Mr. and Mrs. Beaver, we are each accommodated with a nice cozy bedroom warmed by a gum wood fire. We go to sleep under a couple of blankets, and sleep as only one can sleep in this lovely climate. The next morning we are up with the lark, and, taking leave of our kindly host and hostess for a time we mount our ponies and shape our course for Terromiu, (Mr. Stanes' other estate). This is quite as grand in its way as Colacambay, but not quite so extensive. Here Mr. Stanes mingles the two industries, tea and coffee, and from what we could see they seemed to blend very nicely. From Terromiu we return to Colacambay, and have a late breakfast with Mr. Beaver. Mr. Stanes rides part of the way back with me, and for a time I lose his agreeable company. I now wend my way to Tiger Lodge. This is the estate of an old retired Civil officer from Bengal, Mr. N., one of the first acquaintances I make on my arrival from Calcutta. Mr. N. combines the two industries of coffee and tea; he also has a nice little orchard. His estates are about five miles from Coonoor, and I always receive a warm welcome from him when I elect to pay him a visit. On this occasion I am asked to dine and stay the night, which kindly offer I accept. After dinner we light a blazing fire and talk about old times as far back as the Indian Mutiny. The next morning Mr. N. and I ride round, passing in sight of Pellom, another fine coffee estate belonging to Mr. A. We meet Mr. M., the managing proprietor of the Droog Coffee estate who insists on our coming on to breakfast, and on arrival we are kindly received by our charming hostess and enjoy the meal with a mountain appetite. After breakfast we go on to Mr. G. at "Non

such," and after a friendly chat we ride back to Coonoor, having considerably enjoyed my little outing. I myself cultivate fruit, and in my next will give some idea as to what can be done at this elevation, and I shall have something to say about the terrible insect pests, the enemies all over the world to cultivation.—*M. Mail.*

THE EXPLOITATION OF ASSAM.

Oranges and limes figured prominently in our recent note on the concession made to the future Assam-Chittagong Railway. We might have made mention of a commodity less fragrant, indeed, and less suggestive of the golden gardens of the Hesperides, but considerably more profitable. For it is said that the famous oranges of Cherrapoonji, as sweet and luscious as, but much larger than, the Tangerine oranges of European fruiterers) owe their qualities to the lime-impregnated soil in which they grow. All along the steep bluff which forms the southern face of the Cossyah Hills runs a line of lime quarries, the stone from which is brought down in quaint, shallow, flat-bottomed boats (boats which are proving very useful for conveying stores to the Cachar-Lushai force) and is landed on the river bank at and near the sub-divisional station of Sunamgunj. Some say, and the etymology does not seem too forced, that Sunamgunj is truly Chunamgunj—the lime market. Here the stone is burned into lime of excellent quality, the fuel used being the *khag* or reeds which grow abundantly in the surrounding marshes, famous as the resort of innumerable wildfowl, and perhaps the best duck-shooting ground in India. Time was when the lime trade of Sylhet was extremely profitable, when the city of stucco palaces was being built round the broad green maidan of Fort William, and Robert Lindsay ruled Sylhet under Warren Hastings, and made a handsome fortune by trading in lime and oranges. Those times have departed never to return; but the new railway will doubtless use much lime in the construction of its buildings, and will in time afford new markets for Sunamgunj.

The railway will bear not only lime, however, as its wagons rumble along the base of the Tipperah Hills. Tea will doubtless be diverted from the steamers, and the fragrant brown chests stamped with odd superscriptions, the names of remote gardens, will find rapid carriage to the sea. Cherrapoonji boasts not lime and oranges alone, but potatoes and honey, the latter holding imprisoned in its sweets the cloying fragrance of the orange blossom. Coal, too, will come from Upper Assam, and possibly also from the more limited pockets of the Cossyah Hills. The so-called "Dacca cheeses" of Sylhet will find a place on the tables of others than local epicures, and the wonderfully fine *sital-patis*, the "cool mats" of the same district, will reach remoter markets. Possibly the youth of Calcutta will find the rough strong silks of Assam more suitable material for hot weather raiments than the *gharan* suits which have erewhile been their delight. It is not easy to stop when the informed imagination runs riot among the possible prizes that may be seized by a railway running through a region so fertile and hitherto so remote. One important consequence it can hardly fail to effect. It is well doubtless to remember that railways in Burma have not brought immigrants swarming into the waste places of a country at least as fertile as Assam. But in the case of Burma the sea has to be traversed,

and the qualmish billows have to be faced before the Indian emigrant can buy his ticket at a Burmese railway station. Towards Assam the tide of migration has already begun to flow. If any one thing has been established by the debates which have raged over the Assam Labour Laws, it is that migration into the province is rapidly increasing, and that it shows a tendency to emancipate itself from Government control and assistance. In truth the best assistance to the labour seeking planter which Government can possibly furnish, is the provision of a cheap and rapid journey from Behar and Sonthalia. When once a return home is easy, and a yearly visit to the coolie's country becomes practicable, the present difficulties of the labour traffic will in all probability vanish. The planter will find it as easy to obtain labourers as the owner of jute mills at Naraingunj or Serajgunj, and Act I. of 1882 will probably die a natural death. What effect the railway will have on the prosperity of the tea gardens in other respects, it is not easy to guess. At present the tea gardens of Assam enjoy very varying degrees of success, according to difference of soil and climate. The rich new gardens of Upper Assam, with their unexhausted undulating soil, stand on a very different footing from old gardens planted on barren rod slopes in less happy districts. Many of these gardens must be on the verge of extinction, and it is quite possible that coolies free to come and go by the railway may be able to demand better wages, and may thus furnish the last straw of expense. Tea garden coolies are at present paid a wage which in their native hovels in Behar or Ganjam would probably have been deemed a small fortune, and many individuals earn as good wages as an ordinary *kerani*. But the average wage is hardly so high as the average earnings of the indigenous population about them, and it is possible that the railway, by introducing an era of free competition, and rendering it possible for Government to do away with the long term agreements of the present labour law, may, for a time at least, have the effect of raising wages. But this drawback will be attended by many obvious compensations, and though the mind of the well-regulated planter cannot view without regret the closing of any "billets" for for good fellows like himself, it is possible that the industry as a whole would flourish more vigorously were some of the more ill-chosen gardens to be closed.

To the individual planter the railway will be an incalculable blessing. When fever blows hot and cold upon his aching limbs, what a blessing to be trundled comfortably to sea-breezes, and a complete change of air and scene. How surprising and delightful for the Sylhet planter to be able to accept a challenge to play polo next next week in far Lakhimpur. How much more social, more cosmopolitan should Assam grow, and how soon will the present tendency of men to see good only in their own district and its planting ways and traditions be broken down. One more daring glimpse into an agreeable futurity. Some day or another the railway will send its trains, puffing and shrieking, among the quiet glades of the Jatinga valley, and the sinuous line will run from Cachar to Nowgong at the base of great hills the summits of which are clothed with oaks and rhododendrons, growing in cool sweet air. Here may arise, on the site of some abandoned Kooki *jhoom*, the trim bungalows, the church and the club of a hill station, and the last new waltz may yet cause the groves to resound which now hear only the wild ululations of the *hooloole*, or the shrill crow of the jungle cock.—*Pioneer.*

MARKET RATE FOR OLD AND NEW PRODUCTS.
(From Lewis & Peal's London Price Current, 13th March 1890.)

FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.		QUALITY.	QUOTATIONS.	FROM BOMBAY AND ZANZIBAR.	QUALITY.	QUOTATIONS.

The following pages include the contents of the *Magazine of the School of Agriculture* for April :—

INDIGENOUS FOOD PRODUCTS—CULTIVATED AND WILD. IV.

BY W. A. DE SILVA.

Tiliaceæ.

10. *Grewia tiliofolia*, Vhl.—This is a tree known in Sinhalese as Damaniya, and is commonly found in the warmer parts of the island. It has large simple leaves and the bark of the tree is fibrous and thick. The fruit is small and three-sided, having three seeds. The trees bear fruit abundantly in one season of the year. When unripe, they are of a green colour and rather soft and astringent. But when ripe they put on an appearance of a purplish red colour, and the whole fruit, excepting of course the seeds which are rounded and three in number and attached to one another, becomes of a pulpy nature. The berries, when ripe, have a pleasant sweetish-acid taste and could be eaten. The young and tender portions of the tree contain mucilage. As a food product this tree occupies no place of importance. It is said that in the North-Western provinces of India a kind of sherbet is made from the small fruits of another variety of *Grewia*. The wood of this tree is light and loose grained but tough with fibrous matter, and the timber is very elastic; and hence it is generally used in cart building, &c.

11. *Eleocharpus serratus*. L. Sinhalese *Weralu*—is a tree found growing in the warmer parts of the island up to an elevation of 2,000 ft. The tree attains somewhat large dimensions, but takes a long time to do so. The stem is generally not very straight, and the branches come out in large numbers from the terminus assuming as it were an arboraceous form. The leaves are small, having serrate margins and are of a green colour when fresh, but assuming a purplish colour when fading. The flowers contain a large number of stamens and the petals are white and fringed, falling

off early. The fruit is a drupe, and is oblong in shape; it is of a dark green colour, both when immature and ripe. But when it is immature the pericarp is rather hard and astringent; when ripe it is very soft. The seed is covered with a hard covering and the endosperm inside the seed is of a white colour. The pericarp surrounding the seed is used in eating; when ripe it is soft and is of a pleasantly sour taste, but when immature it is astringent and sour. The unripe drupes are sometimes boiled, salted and eaten, whilst the ripe fruits are eaten in various ways with sweets, &c. This fruit is also used for pickles and jellies.

The endosperm found inside the seed is also eaten and resembles the almond in some respects.

Geraniaceæ.

12. *Oxalis corniculata*. Sin. Heen Embulembilya.—Found abundantly in rich moist fertile grounds up to very high elevations. It is seldom found growing in barren places. It is a succulent herb with small green ternate leaves: the three leaflets go to form a circle and each leaflet is composed of two curves. The whole thing appearing to be eight curves in a circular form. The petioles of the leaves are thin and round and rather long. The flowers are small, consisting of a polysepalous distinct calyx of a green colour and a corolla of a yellow colour; the stamens are distinct and the ovary consists of 5 carpels.

The fruit is a small elongated pointed capsule of a green colour and having five sides of angular shape, somewhat in resemblance of a miniature Bandakkai (*Hibiscus esculentis*) fruit. The seeds are arranged in rows. There is a peculiar characteristic in the fruit of this herb. That is, when the mature fruits are touched they begin to spirt out the seeds in different ways. The leaves as well as the whole plant have a mildly acid taste, and the herb when procurable in quantity is used as a salad, and also is cooked into a

curry. The salad of green leaves is said to promote appetite, and the curry and the salad are both considered good eating. The fresh juice of the leaves is used by native medical practitioners in cases of bleeding piles. And the green leaf is also considered a good antidote for *Datura* poisoning.

Aurantiaceæ.

13. *Feronia elephantum*, Cor.—is a tree known in Sinbalese as Divul and in Tamil as Meladikurundu. It attains large dimensions and is found growing abundantly in the hot, drier regions of the island. The stem is straight and large, the leaves are compound pinnate and dark green, and contain glandular patches in them. The leaflets are small and have a peculiar aroma. The trees fruit freely, and the fruits when fully mature are round and large. The fruit is whitish in appearance and is covered with a hard shell. When this shell which is about an eighth of an inch in diameter is removed a mass of pulp and seed is found inside, which when ripe is soft and farinaceous, and of a strong acid-sweet taste. This pulp may be eaten alone or with sugar or jaggery. It is also taken in a liquid form and is very palatable, mixed with sugar and coconut milk. It may be used alone or with rice. A delicious and palatable jelly is made from his fruit, which when properly made is equal to any other fruit jelly. The colour of the jelly is of a bright ruby. The unripe fruit is rather astringent and very acid. Pickles and chutneys are made of it.

The stem of this tree exudes a very clear gummy substance which is equal to the best gum Arabic. The timber is hardly of any use except for the purpose of fuel.

The unripe fruit used in a decoction acts as an astringent, and the ripe fruit is antiscorbutic. The native medical practitioners use the leaves as a successful remedy for headache in infants. The juice of the buds is used in injuries of the eye. The ripe fruit is believed to drive away a hiccup, and cure sore throats, and also is reputed as a good remedy for checking excessive discharge of urine.

COTTON. VI.

By ABA.

After gathering the crop from those varieties of cotton which are treated as annuals in cultivation the plants should be pulled up and buried in the soil or burnt, and their ashes distributed over the land. In the case of perennial cottons the plants should be pruned just after getting the produce and the land should be hoed about three times a year.

Other crops may be grown along with cotton. On the Saidapet Farm, Madras, cotton and Indian corn are grown in alternate rows. There is much advantage to be gained by this. The Indian corn to a great extent helps the cotton plants by shading the land and by keeping down the weeds.

Plucking should be done as soon as the pods (bolls) burst open and expose the cotton. It is better to pick

the cotton off leaving the coverings of the pods on the tree, as by this means a cleaner staple free from a good deal of refuse is obtained.

The cotton after being gathered should be exposed to the sun and preserved in a dry place till it is ginned and prepared for the market. The ordinary Indian cotton gin or churca is composed of a frame of wood in which two rollers are made to turn by means of an endless screw. When the unseeded cotton is held close to the rollers the seeds are quickly got rid of, but the staple comes out matted or napped as it is called. There are improved gins made in America both for hand power and cattle, and I may specially mention the Eagle cotton gin which is being advertised for sale by a Colombo house.*

The cotton or lint is the chief product of the cotton plant, but the seeds are also of value both as a cattle food and an effective fertilizer. Cotton seed intended for planting purposes, after being carefully selected, should be kept dry all throughout. The seed must not be allowed to get wet or damp. To ascertain if the cotton seed is sound, a seed should be cut across with a sharp knife. If sound the kernel will be of a cream colour with dark spots, otherwise the seed is unsound and not fit for planting.

LIFE-HISTORIES OF INSECTS INJURIOUS TO VEGETATION IN CEYLON. V.

By ABA.

The Bean Beetle. *Bruchus*?

1. The beetle magnified. 2. Infested bean split open showing cell.

The Bean Beetle is another Coliopterous insect which, like the rice weevil described in my last article, attacks stored grain. While the attacks of the weevil are confined to cereal grains, the bean beetle attacks beans and other legumes only. There is no distinctive name in Sinbalese for this insect, but it is known to the natives by the generic name of *gulla*.

Beans, peas, gram, &c., infested by the beetle may be at once made out by certain white spots which appear on the grains. The maggots feed inside the seed generally leaving the embryo or growing germ uninjured. When full grown the larva turns to the

* A good gin should neither cut nor nap the cotton but send out the staple straight and smooth, so that the lint may have the appearance of having been carded.

pupa inside the seed, but before doing so cuts a circular lid in the husk of the seed for the escape of the beetle.

In her valuable book "Manual of Injurious Insects," Miss Ormerod describes a beetle (*Bruchus granarius*) as infesting beans and peas in England. She says that the insect lays her eggs whilst the seed is still soft in the pods. With regard to the Ceylon insect I am led to believe that the eggs are laid after the seed is stored, as the preventive methods adopted by the natives simply seek to exclude the insect from the places where the seed is stored.

This beetle is only about the eighth of an inch. Its colour is black, with brown hairs and various white markings; the tip of the tail is prolonged beyond the wings. The head is drooping and the wings are dotted with rows of small pits.

Prevention, &c.—When the crop (as green gram &c.) is brought in, it should be well dried in the sun, and before being put away should be mixed with ashes, lime, chillies, &c. to exclude the beetle. The same thing should be done at intervals of about a month or oftener. Granaries, &c. should be thoroughly cleaned before the new crop is put in, and every means taken to save the seed from the consequences of the vast numbers of the insect sometimes to be found in such places.

(To be continued.)

PADDY CULTIVATION AND TRANSPLANTING.

VI.

BY W. ARTHUR DE SILVA.

Weeding.—In the previous instalments of my paper. I dwelt on the various processes attending the cultivation of paddy by transplanting, and the one on which I am now dwelling, though appearing after an interval of a few months, is not of less importance.

The advantages of weeding and the harm caused by weeds were understood by cultivators from times far remote. Perhaps the recognition of the importance of weeding dates as far back as the cultivation of crops. Cato says:—"Take care to have your corn weeded twice with the hoe and also by hand." In connection with the cultivation of paddy, weeding is of the first importance (though generally neglected in some parts of this country) as the paddy is not a very vigorous plant and able to fight its way with the hardy weeds.

Weeding should be done just a month after transplanting. Then the process becomes easy and also advantageous to the growing crop. The advantages of weeding are great, and the growing crop is allowed to get its full share of nourishment from the soil. Weeds are generally hardy and they grow vigorously taking up the plant food in the soil and thus depriving the crop of a part of its food.

Weeds also, when growing, tend to weaken plants by crowding. The hardy weed asserts its supremacy and throws back the growing plant.

The harbouring of insects noxious to plant life is another bad effect of weeds. By their timely destruction a great deal of damages from insects could be averted. In weeding three things should be taken into account. First the weeds should be pulled out before they begin to flower, because, when they are pulled after seed is produced, a second crop of weeds heavier than the first takes its place.

It should also be borne in mind that weeds should be completely rooted up, and in no case should the rootstock be allowed to remain in the ground. The rootstock or the stem just next to the root, when left in the soil, gives out fresh buds, and the weeds commence growing again. Another point to be considered in weeding is to remove the weeds off the field when they cannot be buried. It is always better and advantageous to bury the weeds in the field itself when it could be done; but where this is impracticable the weeds should always be removed. If they are left lying on the field itself in their original places along with the crop, not only is there danger of their harbouring injurious insects, but they are likely to establish themselves again if rain sets in, or the weather gets favourable in any way for their growth.

Thus the gathering of a good crop depends also on the timely weeding of the fields. In some instances where the fields have an abundance of water, no necessity arises for weeding, as the weeds are kept down by the water, but such instances are very rare.

The weeding of paddy-fields cannot be done by a hoe or any other implement, so the work has to be done by hand. It is done to some extent in the upcountry fields, and then the crop always turns out to be better than in unweeded fields. The want of weeding is greatly felt as stated previously in places where the supply of water is limited. It is not an uncommon sight in the lowcountry to see whole fields covered up with weeds and the paddy plants succumbing. This generally happens where there is a want of water.

In transplanted paddy, weeds have more opportunities of establishing themselves and retarding the growth of a paddy crop. The good yield obtainable in transplanting is owing to the large number of shoots given out by such plants, but if weeds establish themselves, the plants get weakened and only a few shoots are given out.

The work of weeding being a light one could always be entrusted to women and children.

THE ADVANTAGES OF LIMING.

For improving certain kinds of soils, lime is esteemed one of the best means we possess. It is required for the growth of all kinds of cultivated plants, especially those belonging to the natural order *Leguminosæ*. Therefore it is absolutely necessary that lime should be present to some degree in all cultivated soils. While lime is always present in soils

that admit of cultivation, the quantity contained in them is very often insufficient for the healthy growth of certain crops. Therefore if lime be applied to such soils it naturally increases their fertility. On soils of this kind the striking effects of lime is best seen when the soil contains in abundance all the other essential elements of fertility with the exception of lime. Lime not only acts directly as a manure, but increases the other materials necessary for the growth of crops. In most cases the beneficial influence of lime is due to its chemical action in the soil. Lime preserves clay in an "open" condition, thus making heavy soils friable and pervious to water. It also promotes the decomposition of vegetable matter and the formation of nitrates. A soil whose fertility has been impaired by an excess of organic matter can be rendered fertile by a large dose of quicklime. In some soils that are infested with insects an application of lime destroys them entirely at little expense. When applied in large quantities to clay land, it opens and loosens the clay and gives it a certain amount of porosity, and as a consequence it brings about further improvement by exposing a larger extent of surface to the action of the atmosphere. The quantity of lime applied to the soil varies with the purpose it is intended to serve. If lime is applied to destroy an excess of organic matter a large dose will be necessary, but when a soil is naturally deficient a far smaller dose will be sufficient. For obtaining the fullest effects of lime, small doses at short intervals are very effective. Where the opposite course is adopted there is considerable waste and a gradually diminishing effect, as the natural tendency of lime is to sink down into the subsoil. A certain quantity of lime is dissolved and removed by drainage water, and the remainder in a few years sinks below the cultivated depth, or chemical changes take place which render it effete. On arable land, the plough for a season or two brings it back to the surface, but after a time it gets beyond the depth of the plough and is lost. This strong tendency of lime to sink into the subsoil shows us that when liming we should not plough the lime in, but keep it as near the surface as possible. The land should be ploughed first, then the lime spread and simply harrowed in. Burnt lime is much more powerful in its action on vegetable matter than chalk or marl, it should be used with discrimination lest the humus of the soil be unduly diminished. Heavy clays or soils rich in humus are those most benefited by burnt lime. In reclaiming peat-bogs lime is of the highest value. The acid humic matter of the peat is neutralised by the lime, and the conditions are made suitable for the oxidation of the nitrogenous organic matter and the formation of ammonia and nitrates. The general effect of lime is to render available the plant food already in the soil without itself supplying any significant amount. Vegetable remains under peculiar circumstances refuse to decay, and accumulate to an injurious

extent. This kind of vegetable matter is generally found in undrained or badly drained land. To remove this sour humus, lime is generally employed, which by acting upon the insoluble vegetable matter hastens its decay, and "sweetens the land" for by decay these materials furnish carbonic acid and other useful food-materials for plants. The lime thus converts a noxious ingredient into a source of fertility. Lime economises the use of potash; for certain crops, where potash is not abundant in the soil, have to some extent the power of utilizing lime in its place. Lime also improves the quality of grain, grasses, and other crops, the finer grasses on certain lands refusing to grow until the land has been limed. It hastens the maturity of crops and checks the growth of moss and weeds in the soil. The effect of lime on the mechanical texture of many soils is also great. It pulverizes and lightens strong soils, at once improving their drainage and rendering them more easily tilled. It also improves the texture of light soils—provided an overdose be not applied—even when they contain but little organic matter. The avidity of lime for moisture added to the chemical changes brought about by it, have the effect of increasing the absorptive and retentive power of soils to a considerable degree. A deep soil requires a heavier dressing of lime than a shallow one, and deep tillage will call for larger applications than where the cultivation is shallower. A sandy soil requires less than a heavy clay, and soils poor in vegetable matter require less than soils which are rich in organic matter. A small quantity of lime will have greater effect on drained land than a larger dose on wet or undrained land. Lime slakes best and quickest when laid down in small heaps and slightly covered with fine soil. This saves refilling and recarting. The heaps should be put down at equal distances apart so that when the lime is slaked, it could be spread out easily. There should not be too much magnesium carbonate present in a limestone, as it is considered less valuable for agricultural purposes. As I have said before, it is best to apply lime in small doses at short intervals rather than large doses at long periods, as Darwin has shown us that the action of earthworms tends to bury it. The weight of lime per bushel varies from 75 lb. to nearly 1 cwt. according to the particular kind. The better it is burnt the lighter it is comparatively. Pure varieties of limestone yield a little over 11 cwt. of burnt lime per ton. Lime should be applied as a rule to soils containing much clay or humus; not in close contact with nitrogenous manures such as dung or guano, as it sets free the ammonia, which is liable to escape into the air. But lime, since it sets free plant food, tends to exhaust the soil, and "lime without manure, will make both farm and farmer poor."

The following are the chemical changes which lime passes in its application to land:—

1st CaCO_3 . Pure limestone rock, calcium carbonate before burning,

2nd CaO. Lime, calcium oxide, quicklime, caustic lime, lime shells, as it comes from the kiln after burning.

3rd CaH_2O_2 . Slaked lime, calcium hydrate, fallen shells, after water has been put on it, or it has absorbed water from the atmosphere; still somewhat caustic, and usually spread on the land in this state.

4th CaCO_3 . Mild lime, the state to which it eventually returns on long exposure; has yielded up its water and] absorbed carbon dioxide (CO_2 .) On this condition it is equivalent to finely powdered limestone or chalk, as it is identical in chemical composition with them.

Effect of Lime on Soils.

1. Acts with felspar or clay, setting free potash or other alkalies.
2. Acts on vegetable matter, setting free ammonia, water, nitric acid, and carbon dioxide (which it unites with) tending to destroy excess of humus in the soil.
3. Neutralizes organic acids—humic, ulmic, geic, &c.—thus sweetening the soil.
4. Takes up nitric acid as formed by the nitrifying bacteria.
5. Is a plant-food in itself.
6. Renders harmless injurious salts of copper, iron, &c.
7. Opens up clay soil from the "curdling" effect it has on the molecules of that substance.

Soils which contain more than 4 per cent of lime, (carbonate) should not have any applied as a rule.

Loamy and clay soils contain 1 to 3 per cent of calcium carbonate, and defective soils less than 1 per cent.

ALFRED DRIEBERG.

ANIMAL PARASITES.

In these papers I propose to deal with the commoner animal parasites which attack man and beasts, and especially those which find a host in our domesticated animals. Nearly all these come under the class *Scolecida* of the sub-kingdom *Annuloida*. Some of the *Scolecida* are worm-like but others are not, many being microscopic organisms. The animal parasites are collectively spoken of as *Entozoa*—organisms which live within an animal. Most of the parasitic forms are of very low structure, living without any exertion on their own part, and simply imbibing the nutritive juices of the host through their delicate integument.

The first and most important of the seven groups into which the *Scolecida* are divided, is *Teniada* or the Tapeworm family. The body of the adult is jointed, the joints being flattened, and the head is furnished with hooklets or suckers, or both. It has no

mouth or alimentary canal. The suckers and hooklet of flint are for attachment to the alimentary canal or other regions of the host. The head contains such nervous organs as exist—the *Ganglia*, as they are called, which are little masses or knots of nervous matter, containing nerve-cells, and giving origin to nerve-fibres. The head is truly the animal, all the jointed tape-like body which follows it being really reproduced from the head by budding. The head, however, contains no reproductive organs, and the eggs are produced solely by the flattened joints, the adult animal being hermaphrodite. The egg when introduced by some means into the stomach of man or animals develops into the pro-scolex, a little embryo which bores its way through the muscular tissue till it gets to the region where it fixes itself, by means of its flinty hooklets. It then develops from its hinder end a kind of bladder or cyst filled with fluid, and thus constitutes what was formerly called a "cystic worm" under the belief that it was a distinct worm, but is now termed the *scolex*. If now a portion of flesh containing a scolex be eaten by man or animal, the bladder worm fixes itself in the mucous membrane of the alimentary canal, throws off its cyst and becomes at once the head of the full-grown tape-worm or *strobila*, which grows in length by developing segments or *proglotides*. Now again the adult worm produces eggs which pass through the various stages of pro-scolex, scolex, and strobila when introduced into the alimentary canal of the host. It will thus be seen that two hosts are necessary for the development of the *Teniada*, and nearly always these are of different species, some tape-worms passing one part of their existence in the dog and another in man, others living in man and the pig, others again in man and the ox, and still others in the dog and sheep, and so on. But I shall, as proposed, take up the more common of the animal parasites in due course, and firstly those which belong to the family of tape-worms.

(To be continued.)

A SIGNIFICANT EXPERIMENT.

A villager in a communication to a native paper has reported the results of an experiment in paddy cultivation by means of transplanting. The purport of this communication is reproduced here since it is valuable as being one independent of official recognition and corroborating the results of the experiments of Agricultural Instructors in various parts of the Island.

The influence of such experiments as the one I am noticing will no doubt tend to stimulate the goiyas to adopt the means employed, while they are unable to impute, in this case, any interested motives which some are even ready to conjure up, as governing the carrying out, and estimating the cost, of experiments in paddy cultivation, and the goiyas will no doubt readily admit that what one of their own people could do is within their own power.

The experimental cultivation under review shows for one thing that the influence of agricultural education in the island is being felt, and we may hope to see other village cultivators carrying out similar experiments on their own account ere long.

The experiment is reported to have been made in Imbulgoda in the Medapattu of Siyane Korle, and the area of cultivation is given as two *beras* sowing extent (a little less than an acre). The field was first well prepared by digging up earlier than usual, (in the absence of an improved plough which would have done the work more cheaply), and the seed was put in a nursery. When the plants were up, they were pulled and transplanted out in the field. The yield in spite of the damage done by the paddy-bug was 60 *beras* equal to 52½ bushels. The trash or spoilt grain was measured and found to be nearly 8½ bushels, the total cost of cultivation including reaping was R9 02½. (There ought to have been a saving in seed paddy also, as only plants from 12 *seers* of paddy are required for planting an acre.)

It would be well to mention here that for transplanting an acre we require in Ceylon the labour of 12 women for planting, and 2 men for pulling up plants from the nursery, which amounts to a cost of nearly R2 10, at the rate of 12½ cents per woman, and 30 cents per man, per day. But with practice half the number will be able to do the work. Such is the case in India, and the following quotation from Prof. Wallace's "India in 1887" shows the despatch with which the natives do their work there:—

"Forty days after sowing, when the plants are about one foot long, they are pulled by men who using both hands uproot with each hand alternately two or three plants at a time. The plants are retained until the hands are full, and all the while during the intervals between the moments of pulling, the roots are well shaken in the water which is allowed to stand on the seed bed to make the work easier. Each handful or bunch is then freed of all the mud and moisture that will shake off by striking against a stick of perhaps an inch thick, kept standing in the ground within easy reach of the puller. The two handfulls are thereafter tied into one bundle by twisting a few tops of the paddy seedlings in a loose temporary rope, and passing this round the bundle, a few more plants being taken in to add to the length of the band, when it has passed fully half way round. The end is fastened by being tucked underneath the band, and the bundles are ready to be carted or otherwise conveyed to be planted, to be set out the same day if possible. * * * Six women plant an acre per day, when the bundles of seedlings are brought to them by a man."

W. A. D. S.

THE NUTRITION OF PLANTS.

BY C. DRIEBERG, B.A., F.H.A.S.

We saw that as a rule plants got their food constituents from the soil, through the roots, and from the atmosphere through the leaves, and that these constituents had to be elaborated, into organic matt

before they were fit for the nutrition of plants. There are, however, some exceptions to this rule, and these are the parasites, the saprophytes the insectivorous plants, and epiphytes. Now parasites are of two kinds, partial parasites and true parasites. Both these get their food from a living host, but while the former appropriates the crude sap, the latter absorbs the elaborated sap. We saw that the crude sap or the ascending sap consists of water with mineral matter in solution, and that this sap is carried to the leaf or laboratory of the plants (to be manufactured into organic matter) by means of the wood tissue. Thus the partial parasite would have to fix its roots in the wood tissue of the host, and by doing so gets at the water and mineral matter which should have been supplied by the soil. The crude sap which it thus gets will have to be manufactured into organic matter as in the case of ordinary plants, and hence the partial parasites will require the presence of chlorophyl, for we saw that the presence of chlorophyl was necessary for the process of elaboration. Thus the partial parasites are green plants, such as the mistletoe, and the *Loranthus* so common on mango trees in Ceylon. On the other hand the true parasites appropriate the elaborated sap or descending sap which is carried down by the sieve vessels of the bast tissue, and will thus have to fix their roots in the bast tissue. Now such plants need not elaborate food, for they get their food ready made from the host—they rob the food after it is "cooked" and ready for eating—and hence they do not require the presence of chlorophyl, and they are not green. Such are the various parasitic fungi, examples of which are the well-known *Hemelia Vastatrix* of Ceylon and the clover—dodder or *cuscuta* of Great Britain. It is the parasitic fungi that are such dangerous enemies to cultivated plants, sucking their very life-blood. Their presence in vegetable food is sometimes a source of danger to animals, for instance *Claviceps purpurea*, commonly known as Ergot, which occurs on rye and some other graminæ, causes abortion in in-calf cows. In Hungary where rye-bread is much used its presence has caused a large number of deaths resulting from gangrene. The saprophytes or saprophytic fungi, on the other hand, live on decayed or decaying organic matters and are not hurtful to vegetation, as they attack the tissues only after they have begun to decay. The commonest of this class are the mushrooms; a homely instance being the mould on cheese. Another example is the common brown saprophyte (*Mucor Mucedo*), which occurs very commonly in Ceylon, and may be seen on coconut leaves.

The life histories of many of the parasitic and saprobitic fungi are peculiar and interesting, but I must reserve a consideration of this subject for another occasion.

The insectivorous plants are such as are able to capture and digest insects. They are more or less green in order that they may manufacture their own

food when occasion requires. Examples of these are the *Nepenthes* or Pitcher plant and the *Drosera* or Sundew, both of which are pretty common in the marshy parts of the lowcountry of Ceylon. Many of these plants present most ingenious contrivances for capturing insects. Darwin has written a very interesting volume on the insectivorous plants dealing fully with their peculiarities of structure, and habits, and noting various experiments carried out on them.

Lastly come the epiphytes, or air plants, among which are the orchids, which are able to get water and mineral matter from the atmosphere by means of the velamen which imbibes the vapour from the atmosphere, the mineral food being deposited as dust on the aerial roots. Such are the peculiarities in the nutrition of some plants. The parasites and insectivorous plants are among those which are most peculiar in their habits: but the former, as including the parasitic fungi, are perhaps most worthy of study, and indeed they call for far more attention than has been paid to them hitherto.

NOTES FROM EXPERIMENTAL STATIONS.

Kendangamuwa.

The experimental gardens in connection with the schools at Kendangamuwa and Ellawala are laid down with crops of arrowroot and collu (horsegram). The latter crop is however rather sickly, owing evidently to a deficiency of lime in the soil. The arrowroot is growing luxuriantly as the soil is favourable to its growth. I have seen arrowroot growing in abundance in several gardens, the owners of which know very little of its uses, and take no proper care of it. I am at present getting two bits of land cleared for cotton and other products. A portion of the garden is planted with vegetables.

J. A. P. SAMERASEKERE,
Agricultural Instructor.

School of Industry, Haputale.

During the last holidays, Mr. Wijeyasinghe, who is a schoolmaster here, and myself visited a village a few miles off with the object of showing the inhabitants how to use the improved plough. The Howard's Cingalee plough belonging to the school was accordingly sent to a paddy-field owned by our intelligent and respectable cultivator in the village. At the appointed time we went to the field and began the work having yoked a pretty tame pair of buffaloes to the plough. We had not made the matter very public, as we were not quite confident of getting a tame pair of animals which were so necessary for a successful exhibition. The few, however, who were present received a very favourable impression of the good work done by the plough. By way of supplementing what we had done, we spoke to them a little about the merits of the improved implement. The owner of the field now intends to purchase a plough for use in the land, and Mr. Wijeyasinghe also wishes to buy one for his paddy lands at Welipanne in the Kalutara District.

I must not omit to mention that there is not so great scope for the improved plough in paddy cultivation up here as there is in the lowcountry. For we often find that the valleys are too wet and muddy all the year round, and where the land is terraced the terraces are generally too narrow to admit of ploughing.

EDWIN T. HOOLE.

OCCASIONAL NOTES.

"Penguin" writes of the pedigree of poultry:—It has been generally presumed that our present races of poultry, from the clumsy Cochin to the gallant game, are lineal descendants of the common Indian jungle fowl, the *Gallus Bankira*, or, as it is now termed by naturalists, the *Gallus Ferrugineus*. Not long since Mr. W. B. Tegetmeier, who is at the same time an able naturalist and expert poultry-fancier, and whose opinions on such matters carries perhaps more weight than that of any individual writer now living, challenged this popular belief. In the first place, there does not appear to be any sufficient grounds for excluding other species of the *Gallus* besides the *Gallus Ferrugineus* from the ancestry of the present poultry of commerce and "fancy." There are at least three other distinct and well-marked species, viz., the *Gallus Sonnerati*, or Sounerat jungle cock, the *Gallus Stanbyi*, or jungle cock of Ceylon, and the *Gallus Fureatus*, or forktailed cock of Java. Mr. Tegetmeier writes:—"I have no doubt in my own mind that the wild *Galli* have intermixed in not a few instances, and perhaps in not a few centuries in producing our domesticated breeds." Nor does there appear any reason to believe that this view is other than plausible and practical. No doubt there was from the earliest times communication between the Continent of Asia and the Islands of Java and Ceylon, and as, since our knowledge of them, it has proved that four species will and do interbreed and produce fertile offspring, there is no reason to suppose that we are indebted to nothing but the pure and adulterated *Bankira* species for our present races of poultry. The *Bankira* fowl is described as "closely resembling a small black-breasted red game-cock with a tail carried more horizontally than usual." The wide divergences from this type, even in the "Game races," are certainly more explicable if the possibility be granted that the other species have had some share, even if it be but a comparatively small one, in producing them.

* * * * *

Nature thus refers to the peculiarity of trees growing in inverted position: It is sometimes said about old trees (e.g. an old lime in the new gardens at Potsdam) that the present branches are properly roots; and it has been reported that trees may be planted, and will grow, in an inverted position. A scientific enquiry into this matter has been made by Herr Kay, in Germany, taking a number of plants of wild vine (*ampelopsis*) and ivy, about 35 metres high. In 1884 he planted these with both ends in the ground,

and in the spring of 1885, after the tops had rooted, he cut the arch at its highest point. In the first year two of the plants died, but the others (twelve vine and fourteen ivy) grew vigorously, and were still alive this last spring. To test the extent of the inversion, he cut slips from the inverted plants, and planted them in a green-house, some with their natural and some with their artificial upper end uppermost. It appeared that the callus, from which the roots spring, was formed at both ends, but more readily at the naturally lower end, whether this was above or below in the experiment. Herr Kay considers that, notwithstanding several years' successful culture, the inversion was not thoroughly completed. He proposes to continue his investigation, and invites people who have gardens to make like experiments with other plants, recommending willows, poplars, and roses.

* * * * *

Says the *Veterinary Journal*:—Recent investigations have shown that gaseous substances, such as sulphurous acid gas and chlorine gas, which have been often used for the purpose of disinfecting buildings cannot be relied on, and that the only disinfectant that can be depended upon to kill micro-organism, particularly those capable of producing the infectious diseases, is a free application of a solution of perchloride of mercury. It is well to have this solution slightly acid, coloured also in such a way that it shall not readily be confused with drinks and medicines; and proper precautions should be taken to prevent accidents in its use, it being a poison. The solution is made by dissolving half an ounce of corrosive sublimate (mercuric chloride) and one fluid-ounce of hydrochloric acid in three gallons of water, with five grains of commercial writing blue or ordinary violet ink, to give the fluid a conspicuously distinguishing character. The solution is easily made, keeps well, is inexpensive, and easily applied. It should not be further diluted. The use of non-metallic vessels (wooden or earthen ware house-tubs or buckets) should be enquired on those who use it. It can be applied with a whitewasher's brush, and a syringe should be used to squirt it into any nooks that the brush cannot reach. Wherever used the solution should be liberally applied, and should be allowed to remain over night on parts which animals are likely to touch as mangers and racks, and which should be afterwards washed with warm water, in order to remove the mercury.

* * * * *

The stringency of the laws relating to the sale of un-sound meat in Germany is instanced in a late decision in Silesia, where a man named Beier and his wife were sentenced to 15 years' hard labour for having knowingly sold trichinous pork, and thus caused the death of six persons.

GENERAL ITEMS.

Ooconut milk is now being used in Germany in dyeing silk, cotton, and woollen stuffs. It is said to give a brilliancy to the colours used.

It is suggested that plantain stems should be more generally utilized in the feeding of milch cows. It is so used cut up and mixed with other foods in America, where it is greedily devoured, and improves the quality and increases the quantity of milk.

In England it is held that Sir Walter Raleigh first brought the potato over from America: the credit of having done so is given in Germany, or at least in parts of it to Sir Francis Drake. The French again regard their own Parmentier as entitled to most credit in this matter. In England the potato has been known since 1586. In Spain it had been introduced even earlier. It was not till 1772 that Parmentier made his first experiments in potato growing.

Mr. Samuel Williamson Wallace who was farming "Twiglees," Dumfriesshire—a farm of over 4,000 acres—in 1886, and since then was assistant to his brother the Professor of agriculture in the Edinburgh University, as well as lecturer on Agriculture at Herriot-Watt College, is about to leave Scotland and go abroad. Mr. Wallace, who is well-known as one of the most successful practical agriculturists in the South of Scotland, for some years gave the Agricultural Students at the University a practical training on his farm, and by his kindness and good-nature won the esteem and regard of those who spent the summer with him at "Twiglees" and carried away so many pleasant recollections of their stay. We now read of Mr. Wallace having accepted an appointment in Egypt, for 2 years at £,1000 a year. He is to establish a system of agricultural education in Egypt, and advise the government in the agricultural affairs of the country.

The principal industry of Brazil is cotton. The soil is admirably adapted for the production of the raw material, and there are about a hundred cotton-mills already established.

Sir Dinshaw Manochjee Petit the second native of India and a Parsee who has been created a Baronet is one of the pioneers of the cotton-milling industry in the Bombay presidency—the Lancashire of India. Sir Dinshaw is principal proprietor of some eight cotton-mills. He is said to have expended £200,000 for the benefit of the natives of India—his latest acts of liberality being the gift of a site for the Victoria Jubilee Technical Institute, and the founding of a Leper Hospital.

We have to acknowledge with thanks the receipt of the "St. Thomas' College Magazine" for March, and hope that the "old boys" of the College will come to the rescue and help to prevent the financial crisis which the Editor is apprehending now, when the magazine is in its 16th year.

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. IX.]

COLOMBO, MAY 1ST, 1890.

NO. 11.

GEM MINING PROSPECTS IN BURMA: SIR LEPEL GRIFFIN'S VISIT.

THE BURMA RUBY COMPANY—SIR LEPEL GRIFFIN
ON *festina lente*—THE PROGRESS MADE—SIR LEPEL
GRIFFIN'S VISIT TO THE MINES—THE CLIMATE, &C.

(Communicated.)

OW that the formation of Gemming Companies for working the rich deposits of precious stones in Ceylon has excited such interest in the subject amongst your readers, some further information respecting the operations of the Ruby Mines Company in Burma may prove acceptable. There can be little doubt that the series of articles in the *Observer* referring to Streeter's Company and the arguments so plainly put forward through them, along with the persistent campaign kept up in your columns ever since "All about Gems" was published, drew attention to the facilities which were offered by Ceylon for the prosecution of profitable endeavours in such enterprise. It is curiously enough in Rangoon that one of the employees of the Burma Company, casually mentioned to the writer that one of his relatives had been induced to take a share in a Ceylon Gemming Company principally, from having perused the letters in a Ceylon paper under heading of "A Ruby Mining Company for Burma: Why not a London Gemming Company for Ceylon?"

It is now something more than a twelvemonth since Mr. Streeter managed to float the Burma Ruby Mining Company with a considerable amount of éclat in London. There was a perfect rush for the shares not only by capitalists in England, but all over the Continent as well. Engineers were engaged and sent up post-haste to the site of the concession in Upper Burma. Machinery had been already purchased and forwarded to the nearest point on the river Irrawaddy, and matters were to be rushed through with all possible speed. There was an abundance of money at their command as well as the services of experienced and competent men. The Indian Government were eager to push the matter on, and

there was no lack of encouragement by the local authorities. Expectation had been worked up to such an extreme pitch that at the first meeting of the shareholders—6 months after the formation of the Company—the Chairman, Sir Lepel Griffin, felt it absolutely necessary to tell them in a straightforward way that they were in too great a hurry. They must consider that the country was not yet pacificated, the climate was by no means favorable for either Europeans or natives, that the lines of communication had still to be completed,—in fact there was but little chance of anything tangible being done for some considerable period in the future. Another six months have now elapsed and still no apparent results have accrued. More machinery has been purchased and sent forward, more men engaged and sent out, large sums of money expended, medical men provided, and finally a body of about one hundred Goorkha police enrolled and despatched to the scene of operations, but so far as could be seen no progress had been made towards the realization of profits and declaration of a dividend. It was absolutely necessary that inquiry at the approaching meeting of the shareholders should be met with some other reply than the stereotyped "Have patience, wait a little, don't be a hurry, it will all be right by-and-by." The directors no doubt fully realized that those whose money was invested in this venture mainly on account of the liberal promises of large profits so confidently advanced by the promoters would not rest content any longer with appeals to their confidence that everything was in order and they might feel assured their interests were being attended to in the most advantageous way. It was then determined that the Chairman himself, Sir Lepel Griffin, should go out to Burma and report on the progress that had been made, and the prospects of the future. It appears that at the same time he was fully empowered to make arrangements as he might judge to be advisable in the interests of the Company, and he has made use of his authority with no sparing hand as will be seen farther on. Sir Lepel Griffin landed in Rangoon on the 15th February accompanied by Lady Griffin and Mr. Kirby, one of the directors of the Company—an engineer of some note—in connection with the construction of Docks at Bombay. The party remained a few days in the chief port of Burma and proceeded by rail to Mandalay, from whence they were to proceed by one of the boats of the Irrawaddy Flotilla Company to Thabeityu, where the road to Mogok commenced. The consent of the Chief Commissioner had been obtained, as also the permission of Sir Lepel Griffin, to a representative of the *Rangoon Times* accompanying the party to the ruby mines. It seems, however, that every difficulty was placed in his way

by an executive engineer of the Company, who represented that not only were Sir Lepel and Lady Griffin as well as Mr. Kirby going to the mines, but also the Chief Commissioner Sir Charles Crosthwaite and the Financial Commissioner, Mr. Fryer. Under these circumstances there was no means of transport available, and no accommodation at Mogok—nor *en route*; in fact it was impossible for him to go. Having got to Mandalay 383 miles on his journey, his progress was barred, and after eliciting all the information he could he returned to Rangoon. This is what the local press said of this episode:—

“In regard to the return of our representative from Mandalay, we now learn that Sir Lepel Griffin, as well as Mr. Kirby, seemed anxious that he should accompany the party to the ruby mines, but was eventually overruled by the representations of Lockhart, the Ruby Mines Executive Engineer, who from the first exhibited an unwillingness that publicity should be afforded as to the working of the mines. When the want of a pony or other means of transport was put forward as a pretext for our representative remaining behind, he undertook to do the journey on foot at the rate of twenty miles a day, but Mr. Lockhart was so evidently determined not to have him under any conditions that he had eventually to return to Rangoon, his mission unfulfilled, having done all in his power to get to the mines on his own account. One statement of the Executive Engineer, we have reason to believe, was a distinct misrepresentation; he stated there was no accommodation on the road for travellers in which to rest and sleep; but we are now informed there are small ‘*dak bungalows*’ at stated distances of twelve or fifteen miles apart along the whole road. Altogether it would have been much more satisfactory had our own representative been able to proceed with the party and give a plain unvarnished account of what—deny it as they may—the public will be inclined to say the servants of the Ruby Mines Company evidently wish to keep a profound secret.” Your readers will see that the editor of the paper was not far wrong in his deductions, Mr. Lockhart having distinctly stated that he did not care to have newspaper correspondents knocking about the mines, and that the employees of the Company were strictly forbidden to make any communications to the press.

“The district in which the ruby mines lie is about 75 miles in a direct line north of Mandalay. It is a tract of mountainous country about twelve miles east and west by six or seven miles from north to south, with an elevation above the sea varying from 4,000 to 5,000 feet. It includes the larger vallies of Mogok, Kapein, and Kathé containing the villages of the same name more or less inhabited. The whole district is grouped round the southern and eastern side of a considerable mountain ‘*Toung Mai*’ some 8,000 feet high. The elevation being nowhere less than 4,000 feet the climate is comparatively temperate and should prove healthy to Europeans residing at the mines. [Experience so far has proved it otherwise.—*Cor.*] Apple, pear, plum and raspberry grow freely in and around the villages. There is a well defined rainy season from May to October and a yearly rainfall of from seventy to eighty inches; a little rain falling also in the dry season. In December and January the thermometer often falls below freezing-point at nights. In March and April it rises as high as 80° in the shade during the day.” The above quotation is taken from the report made some two years ago by a gentleman of great local experience and eminently fitted for the task which he had undertaken. For some reason not altogether explicable, the climate has not proved

by any means so healthy as was anticipated. The natives of the valley suffer very considerably from fever,—and the immigrant police and coolies have died off in great numbers. The Europeans apparently have been but little better off in this respect than the Indians and Burmans; a number of the younger and inexperienced men having suffered most deplorably. The opinion of Sir Lepel Griffin is worth recording, coinciding as it does in great measure with that of Stanley and Dr. John Kirk in regard to travellers and residents in Africa:—“I fancy the fever is very much due to the rice cultivation, which is in a narrow confined valley and causes a certain amount of malaria; But certainly when we were there the climate was most delicious and invigorating. The inhabitants of Mogok, which is a rather large town of some four thousand people, suffer a good deal. Certainly there was a good deal of sickness amongst the English employees which I think is very much due to their want of knowledge of the country, and unnecessary exposure. They have not hitherto had good food. It has been very difficult to get good provisions there, but I hope that is arranged for now. I shall not believe in the unhealthiness of Mogok when the conditions are favorable, that is to say when there are good houses to live in and good food to eat. I do not consider fever should be worse there than in any other part of India. Of course the jungle parts of India you do almost all over the country find malarious fever in certain months of the year, but Mogok is tolerably cleared now and I do not see why it should be at all unhealthy.”

(To be continued.)

PLANTING IN DUMBARA:

CACAO, COFFEE, COTTON AND RUBBER.

The weather for the past ten days has been showery in the afternoons with very hot sun during the mornings; the showers have been more or less partial however Cocoa on the whole is looking healthy and well, making a good show of strong young shoots. Young coffee looks well for the coming season with a fair amount of crop already set and prospects of more to follow. Several natives have already commenced to grow cotton and where care has been bestowed in the planting it looks promising for a remunerative crop. The natives are being encouraged to grow this product by free distribution of seed from Klarandagalla, from which estate a very fine crop of cotton is being secured. Helopetis, which for a time was playing sad havoc with both cotton and cocoa, appears to be on the wane, but whether permanently or temporarily, it would be very risky to offer an opinion.

You no doubt saw the article in the *Observer* of March 7th on Rubber Cultivation in Ceylon, and I would endorse the last three lines of the article: “It is a pity he (Mr. Betts) should not see some of the old trees in Dumbara and Matale.” The Superintendent of an estate in this district told me the other day he was getting over 1 lb of rubber per cooly per day. From 10 years old trees he took $\frac{3}{4}$ lb. and from 3 years old trees 2 and 3 oz. this rubber last year netted 3s. 9d. per lb. in England, so that though rubber is not generally liked as a shade tree for cocoa, it is worth while considering if the above figures should not deter the wholesale destruction of rubber trees as shade.—*Cor.*, local “Independent.”

COUNTRY-MADE QUININE.

It was recently arranged in the Revenue Department that the manufacture of Cinchona febrifuge on the Government estates be discontinued. Expensive apparatus has been provided for the preparation of quinine, and it is anticipated that with the new appliances the bleached alkaloid can now be supplied at quite as cheap a rate, considering its comparative

efficacy, as any cruder preparation hitherto in use. Dr. Bidie approves of the proposal to substitute quinine for febrifuge in all cases, as the people generally are well acquainted with the efficacy and appearance of the sulphate of quinine, and no other preparation hitherto in use has been able to win the same degree of popular confidence as a febrifuge. The cost of the English-made article has hitherto been the chief obstacle to its general use, and if cheap supplies of the local-made quinine were available all over the country. Dr. Bidie thinks that the consumption would be very large. As the manufacture on the Government estates will, in future, be restricted to the production of quinine and this can be supplied at as cheap a rate as febrifuge, he thinks it unnecessary to consider further the proposal of the Government of India with reference to the use of "Cinchona Febrifuge" in hospitals and dispensaries in lieu of quinine. The factory at Naduvattam will in future be prepared to supply all the quinine required for the Medical Store Department, the price being the same as that of Howard's Sulphate of Quinine landed in Madras. But as regards Native Civil hospitals, the rule that cinchona febrifuge should be substituted for three-fourths of the quinine issued to them, has not been adopted in this Presidency because the medicines for mofussil hospitals and dispensaries have always been paid for by the local bodies concerned. In consideration of these circumstances the Government is of opinion that the manufacture of the solid febrifuge should be limited so as only to meet the demand. It is optional for local bodies to obtain quinine and cinchona febrifuge in such proportion as they think fit.—*Madras Times*, Feb. 26th.

PADDY CULTIVATION PAYING WELL.

Nawalapitiya, March 13th.

Weather fair and likely to remain so for a while now. Tea flushing well, and crops so far very much in advance of last year.

The best information I have been able to get regarding paddy cultivation shows that manuring and careful work pay, as in a piece of paddy land divided by the road into two portions of about seven acres and two acres respectively, the results of the first crop are as follows:—

7 acres, 24 bushels seed paddy, 700 bushels crop, cattle manure used, one crop in 12 months.

2 acres, under 50 bushels crop, no manure, one crop in 12 months, other particulars not to be had.

Another field in Rattota I am told gives a return of 100 bushels on 2½ acres, 5 bushels seed paddy being required, and this for one crop only. In all cases the tax being commuted was very moderate in its incidence.

THE PROPOSED GEMMING ORDINANCE.

REPORT of the COMMITTEE of the CEYLON CHAMBER of COMMERCE in connection with the PROPOSED GEMMING ORDINANCE pursuant to a resolution passed at the general meeting held on 20th Feb. 1890.

The Crown grants issued in respect of lands alienated by the Crown purport to save and reserve to us (the Crown) our heirs and successors all rights and titles to the mines, minerals, gold, silver, copper, iron, tin, lead and other metals and the ores thereof in or upon the said lands, together with full power of entry for the same respectively.

The Committee are not satisfied that the pre-existing rights claimed to be reserved by the Crown at the time of selling the land, had any real existence under their tenure, but at all events it does not appear that at any time these reserved rights have been asserted otherwise than in a perfunctory and nominal way.

The Committee believe that from the time of the English occupation and until the framing of Ordinance No. 7 of 1882, Gemming has been suffered without let or hindrance not only upon lands alienated by the Crown but there has also been no

effectual attempt made to check the operations of Gemmers upon Crown lands. Ordinance No. 7 of 1882 is the only enactment in force at the present time and that Ordinance provides as follows:—

CLAUSE 3.

"From and after the passing of this Ordinance it shall not be lawful for any person to gem upon any Crown land or upon any land in which the rights of the Crown to gems and precious stones have been reserved, for gems or precious stones; unless such person shall have obtained a license therefor in the manner hereinafter provided."

CLAUSE 4.

"The Government Agent of the Province and any Assistant Government Agent within his own district may grant to the party applying for the same a license to be called a 'gemmer's license'; such license shall be in the form (A) given in the schedule hereto, and shall be stamped with a stamp of R1 to be furnished by the licensee."

Hitherto gemming has been carried on almost exclusively by natives, some of the native mines are of considerable magnitude. Pits estimated at from 80 to 100 feet in depth being in existence. These pits are in some instances carefully lined and shored, but many of them are not lined and are of a dangerous character.

English Companies having lately been formed or projected for the purpose of gemming on approved scientific methods by the aid of English and foreign capital, the Government of Ceylon now seeks by fresh legislation to impose upon the new undertaking restrictions and imposts of a very onerous character: in the opinion of this Committee so onerous, that if the proposed ordinance be carried into effect, the new industry which it is the avowed object of Government to foster and encourage, will be checked and all in probability stifled at its inception.

The Committee object to the ordinance now under consideration for the reason that it seeks by ex-post-facto legislation to alter conditions of tenure that have practically obtained for a long series of years and on the faith of which lands alienated by the Crown have been bought and sold.

As regards the character of the imposts the Committee regards the Ordinance as one that in its incidence will almost certainly tax only the gems raised by Companies, the publication of whose accounts is compulsory. They consider that it will be possible for individuals whether European or native to evade the tax altogether, it being practically impossible to recover the Government share by a loyalty at the pits or on gems obtained by surface gemming, a method largely carried on by the natives, and they believe it will be equally impossible to levy a duty at the Custom House. In the case of plumbago, an export duty was substituted for a royalty at the pits, owing to the difficulty experienced in recovering the latter, but the alternative export duty that was possible in the case of a bulky mineral like plumbago, cannot be effectually levied upon gems that may be passed through the Custom House or Post Office without detection.

The Committee strongly deprecate the investment of so much power in the Government Agent of the Province where the land may be situated. Without desiring to question the confidence expressed by the Hon. the Attorney-General in the judgment and impartiality of the Crown Officers, they cannot share to the full, the opinion expressed by him, that it is difficult to conceive that any Government Agent would act arbitrarily or unfairly and they do not regard the possibility of an appeal to the Governor in Executive Council within 7 days as a sufficient protection.

Notwithstanding the arguments urged against such a settlement by the Hon. the Attorney-General, this Committee is strongly of opinion that if Government are resolved to alter the existing law as regards lands alienated by the Crown, the most practicable and at the same time least objectionable method of realising the right, title and interest reserved by the Crown is by the absolute sale of those rights to the owners of the land.

They consider that supplementary grants conveying the rights hitherto reserved by the Crown should be

obtainable by the owner in respect of each block of land for which a Crown grant has been issued (or for a portion of such block when it exceeds 500 acres), and that the purchase money should be in each case R100 plus a sum compiled on a scale similar in principle to or corresponding with the scale of fees recoverable for Surveys authorised by the Governor's Minute dated August 1st, 1861 on this basis a block of 5 acres would pay R112 50, 500 acres would pay R750. It is obvious that small blocks should be taxed more heavily in proportion to the acreage than large ones, the gem bearing area in large blocks forming as a rule but a small proportion of the whole acreage.

The Committee see no objection to the passing of an Ordinance for the Regulation and Inspection of Mines though it is not apparent to them why a legislative enactment should be considered necessary to regulate the scientific mining that it is now proposed to carry on with a due regard to safety, when it has not been thought of importance to regulate the indiscriminate mining in plumbago as well as gems that has hitherto obtained and that has in many cases resulted in loss of life to those engaged in it.

Chamber of Commerce, Colombo, 12th March 1890.

THE MINES AND GEMMING ORDINANCE.

The following is the memorandum on the Draft Ordinance relating to mines of gold, silver and precious stones, adopted by the Sub-Committee nominated by the National Association, and forwarded for consideration to the Sub-Committee of the Legislative Council, who have been entrusted to report on the said Ordinance.

1. The Draft Ordinance involves the questions of (1) the prerogative rights claimed for the Crown, in respect of all gold, silver, or gems found in private lands, (2) the policy of exacting a Royalty on such natural products, and (3) the prudence and justice of the natural provisions of the ordinance.

2. The Draft Ordinance having been already read a second time in the Legislative Council, there is no practical object to be gained in now discussing the alleged right of the Crown to gems and precious metal found in private property. While not conceding the existence of such a legal right, this Association considers that the proposed exaction of a tenth of the produce, is highly objectionable as a matter of policy and justice. It is in the first place, calculated to hamper, if not altogether to destroy an enterprise which has been carried on by the natives of the country for a long series of years, and which always involves a great pecuniary risk and consequent disappointment. It will further have the effect of scaring away, to the prejudice of the best interests of the people, the European capital, which has just been attracted by this enterprise. The uncertainty casually attending mining operations, is too well-known to require special mention; but this Association may direct attention to the fact, that at present the usual ground share of the owners of gem lands is only one-tenth, the remaining nine-tenths going to the operator for the expenses and trouble he incurs—a proportion which indicates the extent of the risk and uncertainty alluded to. It is feared that the additional exaction of a tenth for the Crown, will either put a stop to legitimate gem digging in private lands or (since the operator's risk remain the same) so reduce the ground share, that the owners of land in gem districts will be very injuriously affected.

It must be remembered in this connection, that private lands have been bought and sold, and otherwise dealt with, on the footing of the existing law, and on the faith of the Crown, never exercising or claiming any supposed right as to gems. The exaction of a tenth now by the Crown, will not only injuriously disturb variety of transactions already entered into; but will permanently diminish the value of property. The faith that the Crown would never claim any such right as is now sought to be enforced, was not merely one founded upon the fact of non-user; but was corrobored by the express declaration of the Government, on the alleged neglect of gemming in Crown lands, or lands alienated

by the Crown with a reservation as to gems. For the first Penal Rule in the Rules for the regulation of gemming and mining, promulgated by the Government in 1881 declared, that "the Government will claim no Royalty on or share of gems, or gold found upon land in respect of which a license has been taken out." These Rules were cancelled, since the passing of the Ordinance No. 7 of 1882, but that Ordinance also tacitly not less distinctly, abandons all right to gems, and only requires certain licenses to be taken out for the purpose of gemming.

The Ordinance No. 7 of 1882 of course affects only Crown waste lands, and lands alienated by the Crown with a reservation as to gems—Section 4 of that Ordinance provides, for the granting of a Gemmers' License for a fee of R1, to be collected by means of a stamp duty, and Rule 4 of the Rules framed under the Ordinance and published on the 25th March 1884 enacts, that the License shall be in force for one month only, so that the whole exaction under the Ordinance No. 7 of 1882, amounts to R12 per year. A comparison of this Ordinance with the proposed Ordinance, accordingly presents this anomaly and manifest injustice: viz. that while for gemming in Crown lands, all that a party need pay is R12 a year, the owner of private property will not only have to take out a License for digging in his own land; but have to yield to the Crown and tenth of the fruits of his industry and enterprise; and that too not a tenth after deducting the costs and expenses of the operations; but the tenth of the gross value of gems found. The hardship and injustice of the proposed Ordinance are so obvious and so great, that this Association, desire strongly to press the same upon the attention of the Government.

So far from thus discouraging and throwing additional obstacles in the way of the mining enterprise, the Government should, in the view of this Association, stimulate and foster such pursuits, and actively help in the development of the natural resources of the country. They should afford facilities for the prosecution of enterprises which will circulate capital, give employment to numerous people, induce trade, and give to land owners and those engaged in such pursuits, the full benefit of their property and labour. On the other hand it is to be feared, that the restrictions now proposed to be imposed, will not only obstruct legitimate efforts in this direction, but will to some extent, create illicit gemming, and will tend to produce much demoralization and consequent crime among the people.

Further, this Association strongly objects to the larger powers that are proposed to be placed in the hands of the Government Agent. Without questioning the honour and sense of right of the Government Agent, this Association wishes to point out, that he as the Revenue Officer must be considered in the light of an interested party, whose judgment and action, must often necessarily be affected by considerations of Revenue. To entrust an officer in such a position, with the arbitrary power of granting, refusing, and revoking licenses, is highly undesirable. It will be observed that there is nothing in this Ordinance to control the Government Agent in the exercise of this power. With regard to the power of refusing a license, it is not easy to conceive, what circumstances would justify the Legislature, in vesting in any official the right to deprive a private person of the full use of his own property, subject to Government import. It is true that section 6 of the Ordinance gives to the Governor in Executive Council the power of reviewing the decision of the Government Agent; but this Association cannot view this remedy, if it is a remedy at all, as any thing more than merely illusory.

It is submitted that section 12 of this Ordinance is objectionable both in principle and practice. It enacts that "if any question arises whether a mine is a mine to which this Ordinance applies, such questions shall be referred to the Governor in Executive Council, whose decision thereon shall be final." Thus the Jurisdiction of the Courts of Law is altogether ousted. Apart from the general principle, that the interpretation of law is the speci-

and exclusive function of Civil Tribunals, the question referred to in the above section, is eminently one for judicial determination. A "mine" as defined by the ordinance, is of a very complicated and extraordinary character, and the application of them to any particular case, should be left not to the Government, but to the proper legal tribunals, especially remembering that such decision will involve not only civil rights, but questions of criminal liability and punishment.

This Association ventures to think that much evil is likely to be produced in the practical working of the ordinance. In deciding as to granting, refusing, and revoking a license, or as to the violation of any conditions, in inspecting and examining pits and works, in receiving and collecting the share of the Crown, and in applying the various other details of the ordinance, the Government would necessarily have to make use of the services of minor officials and headmen, and to a large extent depend on their reports and opinions. It will be seen, what a large door this would open to oppression, corruption, and abuse of authority; and to what extent natives in remote villages would be at the mercy of petty officials. The Ordinance seems even directly to contribute to such a result; for section 14 gives to the informer, a moiety of the fines imposed for a breach of its provisions. The practical working of the Ordinance, would leave to a species of tyranny and illegality, to which the Government should not legally expose the native population. As to the provisions of the Ordinance, which relate to examining into the state and ventilation of mines, and regulating matters connected with the safety of persons employed therein, this association is not aware, that mining operations in Ceylon have caused extraordinary accidents and disasters, or are so conducted as to necessitate legislative interference. If such necessity is at any time proved to exist, then such provisions as would meet the case, may be hereafter enacted. At present this association considers, in view of the probable abuses and oppression above referred to, that the contemplated regulations in this respect are undesirable.

(Signed) T. SAMPAYO, WALTER PERERA, S. R. DE FONSEKA, JACOB DE MELL, Members of the Subcommittee of the National Association.
Colombo, 24th March 1890.

COFFEE AND CINCHONA PLANTING IN THE NILGIRIS AND WYNAAD.

Mr. Peter Moir has just returned from a visit to North Wynaad, the Nilgiris and Ouchterlony Valley districts. In the last mentioned, once so famous for some of the richest coffee in India, he fears the fate of Ceylon coffee is rapidly overtaking the fields. For the past season 1,200 tons of crop was originally estimated—then 600—and eventually 320 tons were gathered. Just now the coffee tree branches are covered with blossom, but perhaps two or three leaves at the end alone are left to nourish the tree to bear the crop. This is a picture very common in Ceylon in our declining coffee days. Still the owners of "Ouchterlony" are not touching their coffee, but they have planted up 1,000 acres with tea and are now erecting a first-class tea factory with turbine and all requisite machinery complete, Mr. Holland Porter of Messrs. John Walker & Co., Colombo Ironworks, being on the spot superintending the work.

Mr. Moir saw very vigorous coffee however under the auspices of Mr. Thomas Stanes of Coonoor, one of whose estates he describes as bearing half a-ton an acre with the trees looking quite equal to carrying and ripening it. In North Wynaad, the best days of coffee are over, and although Mr. Moir saw a good deal of cinchona in fields in different parts, not much is being harvested, pending a better market. All are waiting for "the good time coming" for bark. Mr. Moir did not visit the Coorg coffee district on this occasion.—He leaves Ceylon for England about a month hence.

CEYLON TEA AT NEW ZEALAND EXHIBITION.

Dunedin, Feb. 25th.

A. Philip, Secretary, Planters' Association, Kandy.
Dear Sir,—My last letter to you was dated 3rd inst. (press copy enclosed), and I have now again the pleasure of sending you a satisfactory report. The "Ceylon Kiosk" is undoubtedly the most favourite resort in the Exhibition, and Ceylon tea is everywhere well spoken of. The following are the gross receipts at the Kiosk since I last wrote:—Gross takings from 26th November to 1st February inclusive £195 16s 6d, gross takings on February 3rd £2 12s, 4th £3 14s, 5th £3 9s 6d, 6th £5 3s, 7th £2 13 9d, 8th £4 6s, 10th £2 14s, 11th £2 19s, 12th £4 1s, 13th £3 5s 3d, 14th £3 2s 9d, 15th £3 16s, 17th £2 19s, 18th £3 11s, 19th £6 8s, 20th £3 17s, 21st £3 4s, 22nd £4 18s, and on 24th £3 4s: total £265 13s 9d.

Judging has taken place in Teas, Coffees, Spices, Oils, and Photographs, with the following results to Ceylon Exhibits:—

Teas.	Samples.	
Ammunamulle estate	... 3	1st class award
Blair Athol estate	... 3	do
Buchanan, Frazer & Co.	... 3	do
Court Lodge estate	... 6	1st class award
Dunedin estate	... 5	1st class award
Galbodde estate	... 4	1st class award
Keensgaha Ella estate	... 5	do
L H Kelly, Castlereagh estate	4	1st class award
Kintyre estate	... 4	1st class award
Wm. Law & Co.	... 3	do
Scottish Ceylon Tea Co., Ltd.	7	do
Brunswick estate	... 3	2nd class award
Eastland estate	... 3	do
Emelina estate	... 3	do
Hethersett estate	... 3	do
Holmwood estate	... 3	do
Kirkoswald estate	... 5	do
Lec, Hedges & Co.	... 3	do
Mooloya estate	... 3	do
New Peradeniya estate	... 6	do
Rookwood estate	... 3	do
Theberton estate	... 3	do
Torwood estate	... 3	do
Vellaioya estate	... 3	do
Labukelle estate	... 3	3rd class award
Sembawattie estate	... 3	do
Tillyrie estate	... 3	do
Tommagong estate	... 3	do
Wallaha estate	... 3	do

The Tea Jurors were Messrs. J. M. Jones and T. H. Kearns, Merchants, Mr. J. H. Bathgate, Tea Merchant, and Mr. J. Gillanders, Tea Planter, lato of Cachar.

They reported that "the general excellence of the Exhibits required their long and careful consideration, many of the high class teas evidently being show teas, and not being obtainable in mercantile quantities."

Mr. Begg considers it to be somewhat unfair to the exhibitors of purely commercial teas that their produce should be judged against "Fancy or Show" teas, but the jurors were unable to draw a line between the two, and it is, therefore, probable that those who received awards other than first-class may produce for ordinary purposes teas just as good as those who received first-class awards.

But with the recipients of first-class awards will remain the satisfaction of knowing that (whether their exhibits were "Fancy or Mercantile") they have been proved to understand the production of the highest class teas.

COFFEES.		
Parchment Coffee—North Matale Estate	...	First award.
D. Edward's & Co.	...	do
W. Law & Co.	...	Second award
Lec, Hedges & Co.	...	Third award
North Matale Estate	...	Commended
Clean Coffee—Buchanan, Frazer & Co.	...	First award
Do	...	Third award
North Matale Estate	...	Commended

Whole Black Pepper—North Matale Estate	Second award
A. G. K. Borron	Third award
Whole White Pepper—A. G. K. Borron...	Second award
Long Pepper—A. G. K. Borron	First award
Whole Cayenne Pepper—A. G. K. Borron	First award
Cinnamon Bark—C. H. De Soysa	First award
Coconut Oil—Stevenson & Son	First-class award
C. H. De Soysa	Second-class award
Photographs—Scowen & Co., Kandy	Special First-class award and flower studies

Mr. Scowen should be grateful to the Tea Fund Committee for this award, as the photographs were, I understand, purchased by you and sent to adorn the Court.

I regret that all efforts made to recover Messrs. Skeen & Co.'s photographs, forwarded from Melbourne, have proved unavailing.

The certificates of awards will probably not be distributed until nearly the close of the Exhibition, but I shall forward them to you as soon as received.

By this mail I send to you and to Mr. Kelly copies of the *Otago Daily Times* of 21st and 25th Feb. containing a list of all the awards for teas, and a satisfactory article on the Ceylon Tea Exhibits. The list shows that Ceylon teas were better represented and took more awards than all other teas put together.

The Ceylon and Indian Teas Association, Limited, have desired me to request that you will be kind enough to send them as many copies as you can spare of the circular headed "Tea in Ceylon," and having the picture of the Tamil girl plucking tea. They also request that at the close of the Exhibition they may be appointed agents at Dunedin for the Planters' Association, and, to combat the unfriendly remarks and advertisements of certain dealers in China teas, I think this would be advisable.—I remain, &c., (Signed) W. WATSON, Inspector, Colonial Bank of New Zealand.

PLANTING IN UVA.

A CHAPTER OF PLANTING GRIEVANCES—UNPRECEDENTEDLY BAD WEATHER IN UVA—FLUSHING OF TEA RETARDED—AN OMISSION IN GOW, WILSON & STANTON'S WEEKLY TEA REPORT: AVERAGE PRICES FOR INDIAN TEAS—WHAT TO DO WITH THE STRAY DOGS: A SUGGESTION TO THE MUNICIPAL MAGISTRATES—JUBILEE STATUE VERSUS PROVIDENT FUND—SURPRISE AND DELIGHT IN STRANGE COUNTRIES—CHANGE OF THE WRITER'S NAME—WEATHER PROSPECTS.

There is said to be a reason for everything—a balm for every wound—a billet for every bullet, and a whole lot of things for a whole lot of other things. Such being the case (and I am sure we ought all to be exceedingly thankful that such is the case) we in this part of the country will esteem it a favour if anyone will kindly give us the reason for the abominable and unseasonable weather that has characterized nearly every day of the past four months. It has been truly heart-breaking—and the English language in this district has been reduced to a few monosyllabic words, mostly beginning with a capital D. During November, December and January, when we wanted to plant, we couldn't. And when we did have a rainy day or two, and rushed out as many plants as we could, out came the sun again for a fortnight or so and killed 'em all off. This sort of hide-and-seek game kept on till we were well into February, and then—then, if you please—splendid planting weather set in when nobody wanted it and nobody had any plants to plant—and this beautiful planting weather is not over yet. Holy Moses! In the meantime, our tea, which is bursting with impatience to flush the moment it gets the chance, is doing hardly anything, and we have the unspeakable bliss of knowing that a considerable slice of our very best flushing season has already gone with hardly such a thing as a single big plucking to show for itself. Why cannot the sun shine when he is so badly wanted and when he would do incalculable good—and as he has hitherto never failed to do at this time of the year? Who ever heard of a February and March in Uva without lots of sunshine and heat?

This sort of thing upsets all our calculations and will put a petor on all our hopes if it does not stop shortly. I am sure it is enough to make a swine swear and to draw tears from a ham. This wet-blanket weather has put a stopper on lots of things besides tea-flush. For instance, "Mountain Echoes" have been completely smothered and could not make themselves heard through the fog.

There is only one thing wanting in Messrs. Gow, Wilson & Stanton's Weekly Report, which is admittedly the most complete and accurate tea report received there, to make it quite perfect. They do not, as in the case of Ceylon and Java, give us the average price realized by Indian teas. If this want were supplied we could see at a glance, week by week, if our teas were holding their own against India or *vice versa*. And as there is not a reader of their report in Ceylon (and in India too I presume) to whom this information would not be of the greatest interest and value, I trust our good friends, Messrs. Gow, Wilson & Stanton, will take this suggestion into consideration.

The home papers tell us that several tons of quite a new kind of manure have recently been imported into England from Egypt in the shape of embalmed cats presumably dead. Now that is something worth knowing. The local papers inform us that the Colombo Municipal Council finds itself rather puzzled as to the best way to dispose of the (apparently) numberless stray dogs with which the Metropolis is infested. Put these two facts together and further comment is unnecessary. There is any number of estates upcountry wanting manure, and everybody knows that a dead dog is about the highest and most perfect kind of a stimulant that can be applied to the root of a tree. A nod is as good as a wink to a blind horse. So keep your weather eyes open, my worthy municipal magnates (I have a sneaking regard for you, a renowned ancestor of my own having occupied the proud position of a Bailie in a certain western city), and do not let such a glorious opportunity of increasing you country's exports slip from your grasp.

TEA NOTES.—Darjeeling, March 8th.—Ground dried up. No immediate signs of plucking before 1st April or one week later than last year. High winds daily in the afternoon with heavy clouds but unusually clear mornings for the time of year.—Selang, March 10th.—A sharp storm with hail, and not much rain passed over here on Thursday, but did not do much damage. Rain is threatening daily, and is badly wanted. *Fogua* passed off quietly. Tipping begins next week on most gardens. Sun very hot in middle of day.—*Indian Planters' Gazette*.

COOLIES IN ASSAM.—Sir J. Gorst, replying to questions by Mr. S. Smith and Sir G. Campbell, as to alleged ill-treatment of Coolies employed in the Assam Tea Gardens, said that he was asked by the Secretary of State to say that the Rev. Isaac Rowe, of the Anglo-Indian Evangelisation Society, who had laboured for some two years among the Assam Coolies, and who was in no way connected with the Government, had borne his testimony to the generally kind treatment of the Coolies by their employers, and stated that he was certain, from his knowledge of the East-end of London, that hundreds of starving poor in England to-day, would be most thankful if they could be as well fed and housed as the great bulk of the people employed in the tea gardens. The misrepresentations so persistently made on this subject were a great wrong, not only to the planters but the Coolies themselves of whom there were tens of thousands half-starved in the overcrowded districts of Bengal and elsewhere who might but for these statements seek lucrative employment in Assam.—*London Standard*, March 4th.

A NEW TEA FIRM IN COLOMBO.

A well-known and enterprising Foochow Tea firm—Messrs. Bathgate, Pim & Co.—have opened a branch under Mr. F. F. Street's management in Colombo. Messrs. Bathgate, Pim & Co. were one of the first China houses to open a branch in Calcutta and now they do us this honour in Colombo—one among many signs that Ceylon with Indian tea is about to supersede the China article in Western trade.

A TRIP TO THE INDIAN TEA DISTRICTS.

Mr. Maitland Kirwan had a pleasant and no doubt, profitable visit to India. His travels through the Terai, Darjeeling &c., were productive of much useful information. There is no doubt, he says, that "the Dooras" is the coming tea district of India: climate, soil and lay of land all most favorable to tea cultivation. His attention was drawn "to the grave damage caused by the ravages of mosquito blight, which appears to have played havoc in the most distressing manner on various tea estates and for which no cure has as yet been found. This pest is I believe known in Ceylon, but so far has done little or no harm. Forewarned however is forearmed, and planters ought not to treat this pest however slight at present, with indifference."—Mr. J. Maitland Kirwan purposes returning home by the "Bengal" on 26th inst.

PLANTING IN TRAVANCORE.

MR. H. DRUMMOND DEANE'S TRIP TO TRAVANCORE—FROM ALLEPPY TO THE ESTATES—TEA—COFFEE (UNDER SHADE)—CINCHONA—LABOUR—MANURE—ROADS—NUTMEGS AND SPICE, CLOVES AND CACAO CULTIVATION.

Having during a short but most interesting visit to Peermaad district in Travancore been enabled to see a little of the tea and coffee industry of the place, it may interest some of your readers to have a short account of what I saw.

The journey from Alleppy to Kotium is done by boat very comfortably taking about six hours, and the country on either side of the canal is most fertile. "Kotium" is a pretty place but very hot and apparently inhabited by a perfect colony of missionaries of all denominations. From Kotium to Mondakayam, the resthouse at foot of the ghaut, is 32 miles over a road with little if any trace, but straight up or down hill as the case may be, chena cultivation prevailing on either side of the road. The journey is far from a pleasant one, being done in the small bullock carts of the country, at an average speed of 2½ miles per hour. The rest-houses at Alleppy, Kotium, Walrua and Mondakayam being all mere shells of buildings with a few chairs, and wooden bedsteads, but no mattresses, nor pillows &c. nor baths are provided nor even lights, and of food nothing except curry and eggs is procurable, and no drink except water. From Mondakayam I had the loan of a pony and rode up the ghaut 13 miles to the Pass of Peermaad and then about four miles on to Bon Ami estate—where I was most hospitably entertained by Mr. and Mrs. Parker. I had every opportunity given me for seeing the tea and coffee industry of the country, and must premise by saying how extremely pleased I was with the fine soil and splendid growth to be met with on most of the estates in this district. Among others Bon Ami estate with 400 acres of

fine tea and Peshurst adjoining it with some 200 acres of tea would be hard to beat in the Central province, one of the clearings on the latter place of "indigenous" being a perfect picture of jat and growth. On Twyford estate I passed through fine coffee but did not see the tea clearings.

Mai Malle has splendid soil and a capital growth of tea, though not quite as good a jat as that on Bon Ami or Peshurst.

On Glen Mary, the growth of the tea is splendid, though the bushes seem allowed to grow as they please; the cinchona *succirubra* is magnificent.

Woolberaine has a little fine coffee left, but I saw no signs of tea. The rainfall on these places is I am told from 200 to 220 inches and elevation from 3,500 to 4,000, feet but it seemed to me much hotter than it would be at the same elevation in Ceylon and the jungle much heavier and more tropical in appearance; the average yields quoted me were from 350 to 550 lb. an acre for young to old tea and I should think most of these estates will easily average 500 lb. an acre when in full bearing. I next visited The Mount estate, 16 miles further on, and stayed there with Mr. Dighton some days, the elevation being from 3,200 to about 2,500 feet, the soil simply magnificent, deep loam; rainfall about 120 inches, here there is still fine coffee and another 100 acres of magnificent jungle are about to be opened with it. The tea is very fine indeed, a good medium hybrid jat; and cinchona grows splendidly.

Pakanam lower down still, I did not see, but everyone sings its praises as a coffee estate; the proprietor, Mr. Goldie, is an ex-Ceylon planter, and the coffee is grown under shade, the crop this last season being 6 cwt. an acre—the rainfall here being only some 70 inches. Tea does not do as well for want of rain, and Mr. Goldie has abandoned an experimental clearing of 50 acres and is going on opening up coffee under shade.

Manure is obtainable to any extent, there being thousands of acres of good grass land and thousands of head of cattle are driven up yearly from the lowcountry and for a nominal sum any planter can get any number of cattle into his sheds for some six weeks or so in the year, many planters keep large herds of their own as they can graze their cattle free anywhere, and the cost to purchase per head is trifling, some 15s on an average, and in nearly every case all the coffee is cattle-manured yearly as a matter of course. Labor is plentiful and cheap and admirably suited for coffee cultivation, the average being some 27c to 28c. all round including head money to kanganyes &c., but it has this drawback that when the rice crops ripen the bulk of the coolies go off to their villages and cannot be induced to stay against their will; however good the flush on the tea may be. The country round Peermaad is an enormous tract of mountainous but rich grass land, the forest being in small belts called sholas, and I saw very few large tracts of tea or coffee; as a rule the clearings are from 10 to 50 or 100 acres, then grass land, then a bit of jungle and so on, and almost all the forest is in hollows nicely sheltered and not at all steep, the grass land on the other hand being very steep indeed generally culminating in rocky cliffs. Roads—of these sufficiently good for transport purposes, there are ample, but very rough, none of them being metalled, Rs150 per mile being allowed for upkeep and about Rs1,500 per mile for construction I was told. The carts used are very light with very large wheels and take about 5 cwt. for a load each. I was unable to go to the Quilon side, but was told that the growth and jat of tea on the property of the Nagamally Co. was all that could be

desired and that it will probably soon rival Mariawatte. The principal shareholder in this Company is Mr. W. Taylor of Darrawella.

Of *Nutmeg* and *Spice* cultivation there is also a little and, a property of Mr. Anderson, an ex-Ceylon planter and brother to Messrs. Wm. and John Anderson deserves mention. It is situated on the river Kallady, 100 feet above sea level and 24 miles from Quilon; the trees are about 30 years old and much too closely planted being about 20' by 20' instead of 40' by 40', and the consequence is that only those on the outside of the clearing bear fully. Yet the result of $1\frac{1}{2}$ to $2\frac{1}{2}$ cwt. an acre netting (including the mace) about 2s sterling per pound is very satisfactory to the owner the expenditure being trifling. Mr. Anderson assured me some trees are 70 feet high, having been measured. A certain amount of artificial shade is necessary at that elevation and jak and mango are recommended for the purpose. *Cloves* also do well, and *Cacao* grows luxuriantly but is not profitable on account of the difficulty of keeping the crop from ravages of squirrels and other beasts of the forest. As regards manufacture of tea I have little to say having seen but few factories and these of a very primitive description, but the quality of the teas turned out seemed to me excellent, and I have not the slightest doubt that with larger factories and consequently cheapened manufacture, the hill districts of Travancore will be able to put teas into London as cheap if not cheaper than we can do in Ceylon, not excepting even the Kelani Valley, and Kalutara districts, the transport charges from the hill districts being only about 3c per lb. f. o. b. and this with a 52 miles rough road and some 18 to 20 mile river transport. In the south the average cost of labor is only 25c. being I take it as cheap as any in the world. Rice is also cheap, being issued to the coolies at R3 a bushel in the Peermaad district and still showing a very large profit to the estate.

It goes without saying that the proverbial hospitality of the planter is as much to the front in Travancore as in Ceylon, and I left with regret only that I had not more time left me to enable me to visit the other principal planting districts.

THE ATTAR OF ROSES.—Rose water is extensively made in India. At Ghazipore, in Bengal, there are hundreds of acres laid out for the purpose. The harvest is in March and April, and the result of the distillation is to supply about one quart of Rose-water from each thousand of the blooms; but adulteration is very much resorted to, oil of Sandal wood being the medium, and the people of India do not seem to mind much whether they get the odour of the Rose or the Sandal for their money. It is comparatively cheap where it is made, costing 2s or 3s a quart even when unadulterated. Otto or attar of Roses is much more important and expensive. The origin of this condensed perfume is told in one of the romantic stories of the East. It is said that Moorjehan Begum, the favourite wife of Jehan-Geer, was walking in her garden, through which ran a stream of Rose-water, when she noticed some oily particles floating on the surface. She had them skimmed off, and their aroma was found to be so delicious, that means were devised to produce the precious essence in a more regular way. The method is an extension of that which is used to produce Rose-water, but it takes 1,000 bushes to supply about 2 oz. of attar, and its value is seldom less than £20. At that price, and unadulterated, it is sold mainly to Europeans, while in a less pure form it is vended in the native bazaars. It is bought by the Westerns, however, for manufacturing purposes and not to be used in its pure condition.—*Gardeners' Chronicle*, Feb. 8th.

PEARL AND CHANK FISHERIES.—We have received from the Madras Government a copy of "Notes on the Pearl and Chank Fisheries and Marine Fauna of the Gulf of Mannar," by Mr. Edgar Thurston, Superintendent of the Madras Government Central Museum, in connection with which institution the book is published. We shall notice the work more fully in a future issue.

STATISTICS OF JAVA CINCHONA BARK. The Soekaboemi Agricultural Association have sent us their table of Java cinchona bark statistics for 1889 and 1890, the main points of which are as follows. The number of private estates given in the table is 103, but from 25 of these no reply was received. The remark opposite to one estate is "Entirely uprooted; the estate was sold for one guildler"! With respect to another estate also, we are told that the crop of 1890 is to be obtained by uprooting. Several did not crop last year, and a large proportion have the remark "1889 and 1890 no crop." The manager of one estate says: "Shall crop in 1890, if the unit rises appreciably"; while another states: "Shall crop only the half in 1890, if the cinchona syndicate is formed." The totals under the different headings, for which details are given in the table under notice, are as follows:—

	1889 Crop.					
	Estimated Crops in Kilogrammes.	Content of Sulphate of Quinine.	Sulphate of Quinine in Kilogrammes.	Actual Crop in Kilogrammes.	Content of Sulphate of Quinine.	Sulphate of Quinine in Kilogrammes.
Total ...	1,605,900	4.20 per cent	67,509	1,936,935	4.06 per cent	78,733
Government Cinchona Enterprise	450,000	4 per cent	18,000	450,000	4 per cent	18,000
Grand Total ...	2,055,900	4.16 per cent	85,509	2,386,935	4.05 per cent	96,733

	1890 Crop.				Area Planted with Cinchona.	
	Estimated Crop in Kilogrammes.	Content of Sulphate of Quinine.	Sulphate of Quinine in Kilogrammes.	Bouws.	Hectares.	Number of Cinchona trees in the open
Total ...	2,325,250	4.08 per cent	94,899	14,105	10,009.59	32,058,612
Government Cinchona Enterprise	390,000	4 per cent	12,000	1,200	851.58	2,400,000
Grand Total ...	2,625,250	4.07 per cent	106,899	15,305	10,861.17	34,458,612

The compilers of the table append the following remarks:—"The total area of the 103 estates amounts to about 160,000 bouws or about 813,500 hectares [1 hectare = nearly $2\frac{1}{2}$ acres], which are partly planted with other growths beside cinchona, partly uncultivated. From 25 estates, as well as from the Director of the Government Cinchona Enterprise, no reply was received to two applications for returns. The total number of bouws planted with cinchona in Java, inclusive of the Government enterprise, may be estimated at 18,000. The total number of cinchona trees in Java in the open, inclusive of the Government enterprise, may be estimated at 40,000,000." It will be seen that the total Java crop for 1890 is estimated at 5,775,550 lb. against 4,523,000 lb. in 1889.

THE FALL IN CINCHONA BARK

reported by Reuter yesterday is inexplicable unless it be that unsuspected stocks of quinine in Europe are coming to light. Java is the only country now liberal in its supply of bark and there has been nothing as yet to justify a fall to 1½d per unit. Our latest market information from the United States is favourable as may be judged by the following article in the *Drug Reporter* of New York (February 19th):—

THE POSITION OF QUININE.—There are more elements of strength in the quinine situation now than there has been, possibly, at any time during the past three or four years. The influenza epidemic, which has now about run its course, proved to be a factor of the greatest importance in the revivification of the market, as but for its seasonable advent, the demoralization which for so long a time has been a feature of the trade, might have been indefinitely prolonged. The improvement in the bark situation, or at least in the position of Ceylon cinchona should have exerted a powerful influence to remove the depression in the market value of the principal salt of that bark, but the surplus, and in many instances high-priced stock of quinine that has so long hung a dead weight on the market, nullified to a great extent the beneficial effects of the advance in the cost of the crude material. It may be considered surprising that in view of the rapidity with which the offerings of the quinine were absorbed during the height of the excitement that prices did not advance to much higher limits than have been attained; but the necessarily evanescent nature of this extraordinary activity and the natural fear that it would be followed by a corresponding depression, may have operated to prevent such a rise in values. The fact that the movement was accompanied by little or no speculative buying, or what is ordinarily considered as such, bears out this argument as it also emphasizes the lack of confidence in the future of quinine heretofore pointed out. Whatever may have been the causes contributing to the result the fact remains that quinine today rests upon a firmer basis than it did even so late as two months ago. The large surplus stock, so long the *bête noire* of operators in quinine, is gone, or nearly gone, and the wholesale market must in future draw its supplies from the extra stocks held in other markets, notably in London, or from the manufacturers. The latter for the present, at least, are not in the position of free sellers either for prompt or future delivery, and if we have been truly informed they have joined the ranks of buyers, finding it is cheaper to buy back the stock they have sold than to convert new bark into quinine. Some of the operators in this market, according to report, anticipating all this have recently been heavy buyers in London, and their purchases are now beginning to arrive here.

This may develop a weak phase of the situation. It is not certain that all of the stock bought during the last month by distributors has actually passed into consumption, though the continuance of the distributing demand on an active scale to the present time might indicate that it has. If a large proportion of the stock bought by dealers, as some believe, remains on their shelves, it would indicate that the activity of the demand is about at the end, with little prospect that it will be renewed until the fall season sets in, if then. In that case the purchases made in London, which according to some reports are as large, if not larger than the stock taken out of this market, would on its appearance here be likely to exert a depressing effect, and cause the reaction which it has been expected would follow the subsidence of the present activity.

Such a result, if the market is to be governed in the future by the bark situation, must be temporary, and whatever its course may be during the coming two or three months, there is now a probability, heretofore lacking, that in the near future much better prices will be obtained than have been realized in this market for several years.

JAPANESE TEA FOR RUSSIA.

The Ceylon Tea Fund will note the following:—
The Central Tea Association at its recent meeting passed a resolution of an important character. It decided that a determined effort should be made to develop the export of tea to Russia, and with that object it voted a grant in aid to the amount of six thousand yen for five years. In order to raise this money the meeting agreed that the tax of 2 *sen* per box, now levied upon tea intended for transport, should be increased to 4 *sen*. This resolution has not been universally endorsed by the members of the Association. It was evidently taken after due consideration, and the debate that marked its passage by the meeting not only showed that the subject had been fully thought out, but also acquired an aspect of importance from the fact that it was attended by several high officials, among them being the Minister of State for Agriculture and Commerce, and the Minister of State for Education, the latter doubtless taking special interest in the proceedings and being also in a position to afford valuable information owing to his long residence as Japanese Representative in St. Petersburg and Peking. Nevertheless the extra impost of 2 *sen* per box upon tea exported to other countries is obviously regarded with uneasiness. All Japanese engaged in the culture of tea are sensible of the precarious nature of their present foreign market, of the constantly increasing competition to which they are subjected from the direction of India and Ceylon, and of the vital necessity of finding a new outlet for their product. But they are also influenced by the sound idea that a bird in the hand is worth two in the bush, and they feel some uncertainty about the wisdom of imposing burdens on the trade which they already possess for the sake of developing a trade which may or may not be successful. They have accordingly had recourse to the old-fashioned alternative, a petition for official aid. What the result is, we have not yet heard. We doubt, however, that the Authorities will consent to undertake any fresh responsibilities in the nature of trade bounties or grants in aid.
—*Japan Weekly Mail*, March 8th.

THE SHADOW OF THE PEAK OF TENERIFFE [AND OF ADAM'S PEAK, CEYLON].

[We are indebted to a correspondent for drawing our attention to the following letter in the *London Times* with the interesting reference to Adam's Peak.
—Ed. T. A.]

Sir,—I have read with interest the picturesque and vivid letter of your correspondent, the English chaplain at Orotava, in *The Times* of Monday, upon the shadow of the Park of Teneriffe. He ascended the peak at night in order to witness the phenomenon of the shadow thrown across the sea by the beams of the rising sun. The same phenomenon is visible in many parts of the globe, where high solitary peaks, with cone-like summits, rise in proud isolation from the surrounding country. I have myself climbed Mount Etna in Sicily, and Adam's Peak in Ceylon, at night, in order to observe this exquisite, but purely natural, effect at sunrise. It is also visible from the summit of Fujiyama, the peerless volcano of Japan, and I doubt not, has been seen by travellers in other parts of the world's surface.

I write to point out that this phenomenon, though a beautiful and a remarkable, is in no sense an extraordinary or inexplicable, occurrence. Long treatises, exhibiting the most profound scientific erudition, along with a hopeless obtuseness of mental vision, have been written to demonstrate the singularity of the shadow of Adam's Peak in Ceylon, and to discuss the peculiar atmospheric conditions responsible for its production. These do not, in reality, differ from the experience described by your correspondent at Teneriffe, and illustrate no more abnormal incident than the projection of the shadow of an opaque object by a bright light thrown from behind. It will readily be

understood how a solitary pyramid, rising from the sea, or from much lower surrounding levels, lends itself to this situation: and how the rising sun, flaming above the horizon, will throw the shape of such a peak in a perfect isosceles triangle forward upon the opposite space. According as the atmosphere is there charged with mist and vapour, and as the sun itself climbs the firmament behind, so will the shadow contract and appear to stand upon end, until sometimes the spectator upon the mountain top is confronted by a shadowy facsimile of the cone, reared up before him, and appearing to face him with entire uplifted bulk.

This was precisely what I saw in one December from the crest of Adem's Peak in Ceylon. When the sun first arose the triangular shadow was projected, faint and flat, for miles and miles over land and ocean, its head dipping in the distant waves. Great fleecy masses of vapour then rolled up from the valleys, and formed a sort of wall between earth and sky. Simultaneously the sun raced upwards, and the ever-contracting shadow drew nearer and nearer, until it stood upright upon the piled background of vapour, while a prismatic nimbus radiated from its clearly-defined apex. As the glittering disc continued to mount, the mists crumbled, and the shadow itself shrunk and was self-devoured, until it finally disappeared from view.

From the summit of Etna, in the month of April, I witnessed the same phenomenon of the recumbent shadow; but, owing to the transparency of the air and to the less marked outline of the cone, the vertical shadow was not visible.

There are many beautiful sights in creation, and but few more beautiful than these. That, however, is no reason why we should describe as a physical portent what is merely the natural effect of an easily-ascertained causation, or claim it as an evidence that there are more things in heaven and earth than are dreamt of in our philosophy.—I am, sir, yours obediently,

GEORGE N. CURZON.

House of Commons, March 4th.

TOBACCO EXPERIMENTS.

The report of Messrs. Spencer and Co. and Messrs. Oakes and Co., of Madras, on the samples of tobacco grown and cured by Mr. Caine, in the Madura district, is not very encouraging. The appearance of the cigars made from the tobacco is much better and finer, and the color is superior to cigars made from ordinary Dindigul tobacco, but the cigars made entirely from the tobacco do not smoke well, as they burn with a dark ash, and the aroma is faint and slightly acrid, but the cigars made with ordinary Dindigul tobacco with Mr. Caine's tobacco used as wrappers is better, but the outer leaf burns unevenly with a wide black margin. Mr. Jous, the Superintendent of Messrs. Spencer and Co.'s Cigar Department, who has had great experience in the cultivation and the manufacture of tobacco both in this country and the Dutch Colonies, is of opinion that the tobacco has been topped too late, and that too many leaves were left on the plant. He suggests that the curing system to be adopted should be the Sumatra and not the American, which latter is unsuited to the leaves grown in this country; and if it be given strong fermentation, instead of being simply dried and assorted, it would very probably not only be saleable in the Indian market, but could also be exported to Europe. An analysis made of the samples exhibited a very large proportion of nicotine, the chief fault, we believe, of all Indian tobaccos. It is hoped that better results will be obtained with the tobacco now being experimented upon by Mr. Caine, who, from the experience he has gained as regards the quality of the soil, climatic conditions, etc., is hopeful of success.—*Madras Mail*, Feb. 28th.

BARK AND DRUG REPORT.

CINCHONA.—Tuesday's auctions were very heavy, the assortment offered including:—

	Packages	Packages.
Ceylon bark ...	1,414	of which 1,198 were sold
East Indian bark...	1,652	" 1,438 "
Java bark ...	36	" 36 "
South American bark	732	" 237 "

Total... 3,834 " 2,904 "

The standard of the barks offered was considerably above the average, and the auctions were especially notable for the large consignments of East Indian barks, mostly of recent import from Madras, Bombay Calicut and Beyport, which they comprised. There were numerous valuable parcels of officialis bark and also of renewed succirubra. Druggists' varieties, which have been somewhat scarce lately, were in, unusually large supply. At the commencement of the auctions the tone was rather undecided, and buyers appeared to hold off; subsequently the bidding became somewhat brisker, and, considering the magnitude of the sale, the result cannot be called unsatisfactory, although occasionally the level of the previous sales was scarcely maintained. We think that the unit may be fairly placed at 1½d per lb., occasionally reaching 2d, for fine parcels, but more often dropping to 1¼d per lb. The following are the approximate quantities purchased by the principal buyers:—

	lb.
Agents for the Mannheim and Amsterdam works	169,783
" the American, French and Italian works	159,328
" the Frankfort o/M. and Stuttgart works...	75,243
" the Auerbach factory ...	69,580
" the Burnswick factory ...	59,411
Messrs. Howards & Sons ...	57,389
Sundry druggists, speculators, &c. ...	118,526
Total quantity sold...	703,260
Bought in or withdrawn ...	147,914

Total amount of bark catalogued ... 851,174

CUBEBS.—Small sales are made from time to time at current prices, but the principal buyers keep off the market, and prices seem to tend slowly downwards. The threatened extermination of the cubeb plants in the Dutch Indies has lately been forming a theme of discussion among interested parties there. The cubeb vine grows wild in abundance in the Preanger districts of south-western Java, on the volcanic eastern slopes of the Garoet mountain, and the gathering of its fruits is a considerable source of revenue to the natives. The entire commerce of the article is in the hands of the Chinese, who ship the bulk of the berries by way of the port of Cheribon to Singapore, while on small proportion goes by way of Batavia. The natives collect the berries by the simple process of pulling the vine down entire from the forest trees against which it clings. The Dutch Indian Government have not paid any attention to the extermination which is going on, but they are now urged to put pressure upon the natives to cultivate the vine. In certain parts of Java, however, it has already been cultivated by European planters during the last few years.—*Chemist and Druggist*, March 1st.

TEA-TABLE TROUBLES.

There is probably no household article of daily consumption which has been the object of such supreme gush, such audacity of unmitigated puffery, as that of the simple article of tea. At the same time, it is equally certain that there is no article which in its time has passed through such a scathing ordeal of fierce denunciation at the hands of professional and unprofessional opponents as this same commodity. In its days of earlier infancy, when as yet it was unknown as an important article of commerce, it was denounced and anathematised as a social pest, an enemy of mankind. Eminent physicians and learned divines wrote against its use, and published pamphlets in which were enumerated a fearful list of maladies declared to be the result of

indulgence in this "devils' drink!" Even in the time of the first George its use had not gone beyond a few of the wealthy citizens and nobles. Malt liquor continued to be, even to a later date, the ordinary beverage, and the Queen's Maids of Honour were at the time limited to an allowance of one quart of beer each for breakfast and another at dinner. Despite this public denunciation of the leaf from the flowery land, and notwithstanding its fabulous price, it grew in public favour until it became a fashionable beverage. In the first quarter of the present century, it was sold by chemists at a guinea a pound, and when in 1834 the China trade, until then in the hands of the East India Company, was thrown open to private enterprise, the price fell to 10s. a pound. Thirty years ago it was sold for half that figure, whilst today ordinary Congou realises about 4d. or 5d. the pound in bond, the duty being 6d. This great cheapening of the article was brought about to some extent by a reduction of the import duty, but in a larger degree by the action and skilful competition of growers of Indian and Ceylon teas. These new caterers for public favour have, by an excellence of flavour, taken the British tea-table by storm, and whereas 30 years ago British-grown leaf formed but a twentieth part of the total imports of tea, today it constitutes the larger portion of the quantity consumed in this country. This result is the outcome of the British quality of thoroughness.

The Britisher does nothing by halves, and thus it was that, in order to produce a really pure tea, uncontaminated by contact with unclean Asiatic hands, the tea planters of India and Ceylon expended enormous sums in the purchase of the most elaborate machinery. This costly outlay has been crowned with success; but despite all this, the troubles of the British tea-table are not at an end, partly as the result of its success. In this age of infinite quackery, the army of retail traders are ever on the war-path to work out some new device by which rivals may be outwitted and the confiding public victimised, and the planter who has devoted the best years of his life to battling with climate, finds his favourite product tampered with and placed before an unsuspecting public under the most discouraging conditions—a degraded and debased article, to enable the vendors to swell their profits. These remarks apply to the "packet" system of trades under which the larger portion of the retail tea business of this country is now conducted. We are glad to know, and we frankly concede the fact, that there are a few honourable exceptions to this discreditable state of things. The present tea-table trouble of the growers of good, well-flavoured leaf is that, in order to undersell the fair dealer in pure article, the unfair dealer resorts to the unworthy device of making up packets of cheap China or Java rubbish, with, perhaps, just a sprinkling of the genuine article, for "conscience" sake, which, adorned with picturesque and strongly worded wrappers, are palmed off on the unsuspecting as the produce of some favoured garden in the beautiful island famed for its cinnamon and its pearls. Could the unhappy planter whose produce is thus tampered with taste the poor, washed-out, insipid liquor which figures on the tea-table of the unwary purchaser, he would metaphorically tear his hair and rend his clothes. The packets containing this fraudulent article are elaborately designed, and, as a rule, the poorer the contents the more pretentious the wrapper and its label, deceptive in its false gorgeousness as a Dead Sea apple. There are various modes by which a false description of the real contents of these packets are placed on their wrappers: usually it is by printing on them the name of some imaginary tea plantation having no existence in the island whence they are declared to have been "imported direct." These practices, we regret to say, are not resorted to by small, ignorant East-end or suburban dealers, but by wholesale houses of long standing, and otherwise of good repute.

We are fain to hope that this system of "unfair" trade is adopted by the firm without the knowledge of the principals, and, under these circumstances, the attention of a former Chief Magistrate might be called to it. We have before us as we write a choice collection of the unsavoury offspring of latter-day tea

trade, varying in the nature of thin, misleading devices, but all framed with one common aim and object. One of these, the least pretentious in outward garb, but most sinning in the audacity of its romance was ornamented by a figure of a Chinese junk on one side, and on two others by Chinese letters, whilst it bore an imprint in large bold letters of the words "GUADAMA, CEYLON TEA"—Guadama being the name by which the founder of the Buddhist faith was known. At the head of the parcel were printed the sellers' names, their principal being, we understand the mayor of the town in which it was bought—a small place in the valley of the Thames. When it was brought to the notice of this rural mayor that his "Ceylon" packet contained nothing better than a poor cheap China tea, he at once admitted the fact, adding, apologetically, that his shopboy had "inadvertently filled the packet from the wrong bin" There is yet one other case of unfair trading by means of counterfeiting names, in the instance of packets bearing the title of "TAPROBUNDA" in bold prominent letters, beneath which figured the words, nearly as large, "Ceylon Tea," and below all the lettering was the figure of a native of Ceylon. There was no question that this packet was offered for sale as veritable Ceylon tea; yet when tested by a Mincing-lane expert it was found to be a low description of Assam leaf. The address of the vendors was on the packet as the "Importers." When the parties to this method of tea dealing were spoken to on the subject, they coolly declared that it contained twenty per cent of Ceylon tea, and promised that in future the word "blended" should be printed on each packet, which was eventually done, but in such a way and in such small type as to be distinguished with difficulty. Truly, our tea-table has had a bad time, first with slanders, then with a crushing duty, and now with all the unfair dealing which the ingenuity of greedy traders is able to devise. We wish it to be understood that our objection to the almost universal system of unfair trade in this direction has a still stronger warrant than the fact of its adoption under fictitious conditions. We go further. We say that the poor, flavourless imitations of properly-prepared fully-grown tea possess none of the essentials which render it of value to tea-drinkers, being deficient in *thème*, the active principle which sustains and restores the waste of the human body.—*Citizen*, Feb. 22nd.

THE BENGAL RICE TRADE,

On more than one occasion in the last two years we have drawn attention to the injury inflicted on the Bengal rice trade by the excessive penalties awarded against shippers by London Arbitrators. It would appear from a review of the rice business for 1889, which is published in a leading home trade journal, that the effects of the evil complained of are being manifested in an alteration of the conditions under which shipments have hitherto been made, if not also in a serious decline in their volume. According to this review, "shipments fell considerably short of the previous year, amounting to 53,400 tons against 100,000 tons in 1888. Contrary to the custom of late years, shippers brought forward a considerable portion of this year's supplies unsold and realised after arrival, thus avoiding the ordeal of arbitrations to which most of the sales to arrive were submitted." It may be necessary to mention that sales of Bengal rice were, as a rule, made on small samples drawn by London rice brokers from the shipments of the previous season. With these small samples the bulk shipped was supposed to agree exactly in colour, size of grain, etc., and in default, heavy penalties were exacted from the shippers. The arbitrators did not take into account the smallness of the samples on which the sales were made, nor the repeated "handling" to which they had been subjected before the arbitrations took place, though in other branches of the produce business due account is taken of these considerations. The complaint of the Indian shipper is that when he is unable accurately to match the small sample on which he has sold, the award given against him does not represent the difference

in value between his "sale" sample and his shipment, but takes the form of a heavy penalty inflicted for his failure to ship the rice which he found it impossible to procure.

By these unwise severities the development of the trade has been checked; some shippers have ceased to deal in white Bengal rice, and others have preferred the risk of selling "after arrival" at home to that of selling "according to sample." It may be a slight consolation to Indian shippers to know that hardly as they have been used, their neighbours in Japan have been suffering even more severely from a similar cause. Japan shipped fully three times as much rice to Europe during 1889 as was exported from Bengal to the same destination. The greater part of these shipments appear to have gone to the European Continent, where, it is said, "as much as two shillings per cent. (equal to 25 per cent. of the shipping value) were awarded for inferior quality." It is not surprising to learn that "these decisions have been the subject of much criticism among the shippers, and they have decided, almost as a body, not to enter upon further engagements unless on the basis of London arbitration." We fear that our friends in Japan will find that in referring these disputes to London for settlement, they have not greatly bettered their position though it may be that they have chosen the less of two evils. It will have been seen from the foregoing remarks that the rice trade of Bengal is in an unsatisfactory state, and that if its development is to be encouraged transactions must take place on a more equitable basis. The Secretary of State has of late given much attention to the improvement of the quality of Indian wheat, with a view to the extension of the trade in this article. We have little faith in the reforms which, mainly by his influence, the corn trade associations at home have been induced to adopt, but the officials of the India Office might, with advantage to all concerned, read homilies on equity and moderation at a "conference" of London rice brokers.—*Englishman*.

TROUT ON THE NILGIRIS.

Some of our readers may be interested to learn, that the last lot of trout ova imported from England, and which arrived in Madras last December, under the care of Mr. W. L. Edmiston, has proved a success. Guided by previous experience, the hatching arrangements, which were carried out on the Dodabetta Estate, under the supervision of Dr. Ross, were all that could be desired, and resulted in 2,094 healthy trout fry which have been distributed in the following streams and reservoirs:—Pykara river 988, Emerald Valley river 340, Ooty Lake 180, Marlumund reservoir 90, Dodabetta reservoir 80, and Dodabetta estate breeding pond 416. Both the Pykara and Emerald Valley rivers are as promising trout streams as can be desired, and appear to have all the requisite conditions of food supply and good water. It may therefore be concluded that trout have at last, and after several failures, been successfully introduced to the Nilgiris, and if they increase and multiply, as it is hoped they will, the much-abused Game Association will not have lived in vain. In addition to these fry, which were procured at the expense of the Association, Mr. Wapshare has put 10,900 ova direct into the upper waters of the Pykara River, which he imported at his own expense. It is confidently hoped that a good percentage of these will have hatched, and will materially assist in the stocking of the river.—*M. Mail*, March 11th.

NOTES AND PRODUCE. TEA—CAFFEINE—CINNAMON.

The Lane is on the tip-toe of expectation in regard to the tea duty, and various doubts and anticipations are expressed to what is to happen. The question asked is: In the event of reduction or abolition, will the alteration take instant effect, or will it be prospective?

In view of anticipations about the tea duty and its possible abolition, the following particulars given in a Mincing Lane circular, showing the effect of a high

or low duty upon consumption, will be interesting:— "In 1852, the last year when the duty was 2s 2½d per lb., the quantity of all kinds of tea entered for home consumption in the United Kingdom was 55,000,000lb. In 1854, the duty being reduced to 1s 6d, it was 61,000,000lb. In 1856, when the duty should have been 1s according to law, but still remained at 1s 9d, to which it had been raised by Mr. Gladstone in the previous year, instead of 1s 3d, the total quantity entered was only 63,000,000lb. In 1857 it rose to 69,000,000lb, the duty being 1s 5d. In 1863 the duty was reduced to 1s, and the quantity entered for consumption rose to 85,000,000 lb., the average price of sound common congou being then 1s 0½d per lb. in bond. In 1865, when the duty was reduced to 6d, the average price of sound common congou in bond being 11d, the consumption rose to 100,000,000 lb. Ten years afterwards (1875), the average price being still 11d and the duty 6d, the quantity increased to 145,000,000lb. In 1885 the average price of sound common congou had fallen to 8½d, the duty being still 6d, and the quantity entered for home use reached 182,000,000 lb. Last year the quantity entered was 185,622,000 lb., the duty being still 6d, and the average price of sound common congou in bond only 4½d. It will be seen that when the duty was reduced to 6d per lb., twenty-five years ago, the tax represented a little over 50 per cent of the bonded price of common congou, but now it is the equivalent of 150 per cent!"

What is Caffeine? asks the *Grocer*. Although coffee and tea are usually regarded as containing nothing in common beyond their power to furnish agreeable beverages, it is a remarkable fact that the active principle in each is identical. This has been proved "up to the hilt" by many chemists, who, recognising the economic importance of these commodities, have carefully investigated their properties. Caffeine, or methyl-theobromine, as it is more correctly termed, is the bitter ingredient of coffee, and was isolated in a pure condition as long ago as 1821. It is curious to notice that no less than four different chemists—Caventon, Pelletier, Runge, and Robiquet—succeeded in preparing this substance almost simultaneously, although they were working quite independently. Caffeine occurs not only in the berries of the coffee plant, but also in the leaves.

In 1828 Berzelius discovered that tea contained a certain bitter principle other than tannin, and to this he gave the name of theine (French, *thé* = tea), and although at the time he rather suspected that this substance was identical with caffeine, this was not proved until later by Jobst and Mulder. Tea contains from 2 to 4 per cent of caffeine. Professor Johnston, remarking upon the greater proportion of caffeine in tea than in coffee, says "that as we generally use a greater weight of coffee than we do of tea in preparing our beverages, a cup of coffee of ordinary strength will probably contain as much theine (*i.e.*, caffeine) as a cup of tea.

Green tea contains more caffeine than ordinary black tea, and Pereira in his "*Materia Medica*" specially speaks of it as "diminishing the tendency to sleep." Professor Johnston says that tea "excites the brain to activity and produces wakefulness." It is evident, then, that the physiological action of caffeine (the important constituent both of tea and coffee) is to diminish the waste of tissue, and as a matter of course, therefore, to diminish the necessity for food to repair that waste. It is also evident that the best tea or coffee must contain the highest percentage of caffeine, for it is to this constituent that they owe the properties which have given them their important position in the social habits and trade of this country.

The imports of Ceylon cinnamon into London this year to date have been nearly double those in 1889, and the deliveries having fallen off somewhat; the quantity remaining on hand on the 22nd inst. was about 1,600 packages larger than that in the former year. At the first series of quarterly sales for 1890, held last week, 2,490 bales Ceylon, besides ten parcels and twenty-eight boxes, were offered. Instead of any-

thing like buoyancy, there was flatness, and the biddings for the fine qualities were so slack that they ruled 1d to 2d per lb. below the Novem'ler rates, the proportion sold at the decline being rather small; but the very finest growths fetched the former value. The other and commoner sorts also found a dull market, but holders were desirous of affecting a clearance, and at a reduction of about a halfpenny per pound the rest of the supply was taken off with a pretty fair competition towards the finish. Ordinary to good first quality was realised at 6½d to 10½d, fine at 1s to 1s 3d, and superior garden plantation at 1s 4d to 1s 6d; also seconds at from 6d to 1s 1d, with extra at 1s 4d; thirds at 5½d to 11d, and best at 1s to 1s 2d; fourths at 5½d to 9d; parcels "unworked" at 5½d to 8d; and broken (in boxes) at 5½d to 6½d per lb.—*H. & C. Mail.*

A PRODUCERS' UNION—THE NEED OF THE DAY.

Tigris agit rabida cum tigride pacem Perpetuam, sœvis inter se convent ursoris.—Juvenal.

Tiger with tiger, bear with bear, you'll find In leagues offensive and defensive joined.—*Tate.*

To the Editor of the *Home and Colonial Mail.*

SIR,—The readers who have read No. 9 of the *Spectator*, issued on March 10th, 1710, will recognise the quotation from the Roman satirist, which served as the text for the impishable essay on "Clubs," commencing as follows:—"Man is said to be a sociable animal. ... When a set of men find themselves agree in any particular, though never so trivial, they establish themselves into a kind of fraternity."

The purpose of this letter being to impress upon those whose cause you support and represent so well the need and the advantage of combination, I have ventured to borrow the text, without personal reference to the tiger and barring the bear.

The absence of solidarity among producers has long been a source of wonderment to those who see the benefit of organised action for common purposes, and who note how its utility is recognised in almost every department of social, political, and commercial life.

We have learned many things from those who are termed Socialists, some of them bad and some good. In the latter category I would place the lesson that there is an alternative to Individualism, and that "free and unrestricted competition" is not a divine revelation, but a superstition begotten by man's inherent selfishness. But superstitions die hard; and the Individualism which has marked the history of our industry more than that of any other survives. What is the result?

Producers having to face strong organisations seeking their own ends—and legitimately so—are beaten in detail, each one fighting for his own hand; and their interests go to the wall.

Does the history of the past twenty years show any instance of a great question affecting them being settled in their favour? They have protested and schemed and struggled in vain. Why? Because they have no machinery for combined action, nor the spirit to create it. It matters not whether the dispute is with the dealers about conditions of sale, or with the warehousekeepers about their charges, or with the ship-owners—down goes the producer before every fresh demand.

What is the remedy? Just to learn the lesson which John Burns, Broadhurst, and Company have taught their clients and to put it into practice.

But how can so many separate and conflicting interests be reconciled the critic will ask? My point is that the interests are *identical*, and are only separate by reason of an old-fashioned exclusiveness which still holds sway in high places. Events and necessity are rapidly tending to concentration of interests and the wise policy of amalgamation; in witness whereof I cite some instructive figures before me. During 1889 ninety-five million pounds of tea were shipped from Calcutta, of which sixty-three millions went to the credit of just ten firms, and twenty millions to ten other firms; that is to say, eighty-five per cent. of all the tea produced is controlled in Calcutta by twenty

firms, representing, let us say, thirty independent interests in London. If, with the assistance of the six or eight leading firms of brokers here, who negotiate the sale of four-fifths of the production, means cannot be found for acting in concert for the common good, then, indeed, the case is past curing.

The mention of brokers may lead another critic to ask, What is the use of brokers and their association if they cannot safeguard the interest of their employers? That is a straight question, and shall have a plain answer. The Brokers' Association exists for the purpose of collecting statistics and—subscriptions. Its members are engaged in keen competition and rivalry among themselves, and but too faithfully reflect therein the spirit which has hitherto governed the action of those whom they serve. Moreover, the fear of "the boycott" effectually deters them from taking up an independent attitude on any question likely to be unpopular with their customers even when it would be just and reasonable to do so.

But the practical reader will ask, For what ends should producers especially combine? I will indicate a few that occur to me. A reduction of the marine and fire insurance premiums, now quite out of proportion to the average risk, owing to the great care bestowed upon tea. A reduction of the three months prompt to a much shorter period. Restriction of the days on which auctions are held; sales three times a week being, in the opinion of many, prejudicial to the stability of the market. Making warehousekeepers responsible for loss on contracts cancelled, when work for which they are paid is badly done. Making brokers responsible for the completion of contracts, subject to the arbitration of a duly constituted Committee of Arbitrators, in place of the present system under which certain buyers decline to take delivery on too slight pretences. Agreement to abandon the present pressure to sell before teas are ready for delivery. The abolition of the 1A draft allowance—a tax of £1 per cent upon the value of the crop. Reduction of the exorbitant rate of freight—now 45s net per ton from Calcutta.

Necessity is the parent of invention; the need of a Producers' Union is evident. Is there no genius forthcoming to call it into being?—Yours &c.,
—*H. and C. Mail.* SIGMA.

TEA PLANTING DOWN SOUTH.

(By an Old Hand.)

Udugama has the exact climate for tea; but we must import the necessary fertility of soil, unless we choose to wait till the tea roots reach the stiff iron soil far below. Grumbings are again heard about the road even when the Government has given us a very popular road officer all to ourselves. His genial presence in our midst is a boon, but we want that road finished. The Sinhalese holiday is causing all things to hang fire. That word "the Sinhalese holiday" used to be a terrible bogie, but we are making ourselves independent of it. We can't get a fowl for love or money from the villages. A Buddhist crusade or revival is said to be the cause—"Thou shalt not kill" a koli, but any number of men. There are lot of murders, but precious few kolies for a change.

PREPARED PAPER FOR LINING TEA BOXES V/S. TEA LEAD.

We have received from Mr. Maitland-Kirwan, a sample of prepared paper which is intended to supersede the use of tea lead in lining chests of tea for local and export purposes. The paper is very firm in texture, waterproof and of course much lighter than the thinnest of lead. In sending you the samples (which we circulated in the Fort) Mr. Maitland-Kirwan writes to us as follows:—

"Elkaduwa, March 18th.—Referring to our con-

versation some weeks ago when I mentioned I was experimenting on a certain prepared paper to take the place of tea lead, I have now to inform you that these experiments have proved entirely satisfactory. I had 50 lb. of Elkaduwa tea packed in this paper in London and sent out here: on opening it the tea was found to be in perfect condition. I am now having a consignment sent home packed in this paper instead of lead for sale in the London market.

"I enclose a sample of the paper in question. It is perfectly air, and water-proof and more pliable than lead, and not so easily torn. The price is infinitesimal as compared with this latter, besides which, considerable saving will be effected in freight and railway carriage here and at home and waste in cutting this last item, a considerable one in tea lead. I have delayed introducing this matter prominently until I had thoroughly tested it. The point now to be solved is how will the home trade receive it? and this appears to me to be a matter for the Planters' Association to take up, for if Ceylon generally adopt this paper in place of the lead the trade will be unable to help themselves. I have already had numerous applications from India for this paper, but until it was thoroughly tested I declined giving it prominence there. I am now going to send samples of it to the Bengal and Madras Presidencies."

The testing of this substitute for tea lead is certainly a matter of very great practical importance to our tea planters who will be much interested in learning the result of Mr. Maitland-Kirwan's further experiment. If it prove successful and the home trade do not object, we may be sure that the demand for Ceylon will be very large. Our correspondent should send samples to the Chairman of the Planters' Association and also of the Chamber of Commerce. One objection suggested to us has reference to the cutting of the paper for the sampling of teas: would gumming over be sufficient? We have no doubt, that further criticism will be offered on the samples being seen; but it is possible that requirements could be met by paper still further adapted and improved.

GREEN TEAS; KINTYRE PREPARATION.

We are enabled to publish the following Report and letter:—

Report No. 155. Report on Kintyre Green Teas. Samples received from John T. Rae, Esq., 4th January 1890.

UNGLAZED B. P. GRADE NOT MARKED.—*Leaf*: Blackish, yellowish, well twisted, wiry O. P. leaf, with fine silvery tip, very pretty desirable leaf.

Liquor: Fine pure, pungent China Moyune green tea. Value 1s 3d.

Infused leaf: Perfect color for green teas, being of uniform yellow greenish and quite free from oxidization.

PEKOE GRADE NOT MARKED.—*Leaf*: Rather well twisted, wiry blackish yellowish, Pekoe sort white tip.

Liquor.—Similar in color and character to Broken Pekoe. Value 1s.

PEKOE SOUCHONG NOT MARKED BOX 449.—*Leaf* Blackish, little mixed yellowish, useful Pekoe Souchong sort.

GLAZED B. P. GRADE NOT MARKED (240s.) *Liquor* similar to Pekoe. Value 10d.

Leaf.—Small, even, nicely glazed, bright black and yellowish, very well twisted wiry, leafy B. P. sort some tip.

Liquor.—Similar in color and character to unglazed B. P. but more pungent and preferable. Value 1s 2d. The tip in this grade has been lost in the glazing process for which reason it is worth less money. The liquor, however, is slightly preferable, being more pungent.

GLAZED B. P. GRADE NOT MARKED (BOX 281).—*Leaf* of very similar appearance to the foregoing broken pekoe. *Liquor*: Much as. Value 1s 2d.

The quality of these teas as green teas is highly satisfactory—in fact they are far and away, I may even say the only really fine green teas I have tasted in Ceylon, with the exception of some samples lately received from Mr. H. D. Deane of Kintyre. As specimens of what green teas should be in cup and infused leaf, they are about as desirable as it is possible to make them, the only fault with the leaf is a slight irregularity in the *sorting* which can easily be corrected by a little attention being paid to the sifting.

I may mention that these teas closely resemble in cup character the finer lines of the best district China and Japanese greens. The most popular classes of tea in use in North America, as shown by the fact that out of total export of 51 million lb. of China tea this season to the United States to the middle of November nearly 82 million lb. were of this unfermented class, 14 million being Oolongs (*partially fermented*), whereas the black (fermented) tea corresponding to the ordinary Ceylon made black leaf, was only a little over 1 million.

I have already expressed an opinion in the local newspapers that if Ceylon planters resort to shipping any quantity of their teas to the States they *must* make teas to suit the American taste, *i.e.* greens and Oolongs and *not* their ordinary make of black fermented tea, for which there is only a very limited consumption.

I am very strongly of opinion that there is a great future in the States for teas of similar character to the above and that they will soon become become quite as, if not more, popular than Japans did shortly after their introduction from 15 to 20 years ago.

The export of greens from Japan alone last season 1888 to 1889 reaching nearly 23 million lb. to which China added a further 15 million lb. The fact that these Ceylon teas are entirely free from foreign facing and coloring matter and therefore less injurious is, I consider, a strong point in their favour, now that all China teas entering the States are subjected to a strict Customs examination and in cases of suspected adulteration to analysis.

The consumption of green tea in England is of course comparatively small, some 7 millions lb. annually only, but I think there is not the least doubt that Ceylon greens, if they can be made as fine as the teas under notice, will drive the colored China article out of the market, as soon as they are shipped in sufficient quantity to supply the requirements of the trade, in the same way that Indian and Ceylon black teas have and are still doing.

In conclusion I may mention that my brokers, Messrs. H. A. Hertz & Co., sold in London a short time back some Ceylon so-called Oolongs of much inferior quality to the teas under report at 1s 4½d for broken pekoe, 1s 5d for pekoe, and 10½d for pekoe Suchong.

Colombo, 7th January 1890.

(Signed) FRANCIS F. STREET.

(Copy) Kintyre, Maskeliya, March 28th.

My Dear Street,—Yours of 21st to hand and thanks for congratulations. You are now at perfect liberty to publish any of your reports made either to me or to Mr. Rae on the Kintyre green teas. I consider it only fair to you that the public should know that it is almost entirely due to encouragement I received from you, that I was induced to make a break for the London market, which of course entailed some outlay on requisite temporary trial machinery. I am sure that those who are now turning their attention to green teas will do well to consult you on the subject before making large breaks.—Yours very truly,

(Signed) H. D. DEANE.

P.S.—I shall be glad to either teach people by letter or on the spot for a consideration. The machine, I understand, will cost about R500.

CINCHONA-GROWING IN JAVA.

The first shipment of Java cinchona bark in commercial quantities was made on September 28th, 1869, when fourteen packages, weighing altogether 900 lb left the island for Holland. The consignment was in the hands of the Netherlands Trading Company, and that organization called in two professors to give an opinion on the trial shipment. Their report was very favorable, and the bulk of the shipment was sold privately to manufacturers and dealers. Five of the purchasers afterwards also gave their opinions of the bark, but all agreed that, owing to its immaturity and insufficient alkaloid contents, the cinchona was unfit for manufacturing purposes, although it would answer admirably for druggists' use. In 1870 the Java exports amounted to 41 bales and 28 cases, and on October 20 of that year the first public auction of 876 kilos. took place in Amsterdam. Up to 1883 one or two public sales were held every year; last year there were ten, and for 1890 the same number is announced again. The first private planter to commence cinchona-growing in Java was Mr. K. F. Holle, in 1866; but not until about eight years later, when the first consignments of the rich Ledger barks had been shipped to Europe and realised enormously high prices, did private planters commence to pay special attention to the article. At first the intention of the shippers appears to have been to send all the Java bark for sale to London, where a market already existed for the article; but the Netherlands Trading Company determined to create a center in Amsterdam, and the importance which that market has now acquired demonstrates the wisdom of their decision. In 1878, when it had been shown beyond doubt that the most valuable cinchona alkaloids were found principally in the outer bark layers, the then director of the Java Government plantations, Mr. Moens, decided to adopt the system of scraping the order Ledger trees; but after some seasons the scraping was found to be injurious to the trees, and since 1886 this method of harvesting has been abandoned in the Government plantations, though it is still followed by a few private planters. At first all barks were cut to the uniform size of 20 centimetres (about 8 inches), and brought to market in quills, all bark which could not be harvested in this manner being crushed to a coarse powder. The trade in the beginning offered considerable opposition to the sale of this powdered bark, as it was believed to facilitate sophistication, and also on the alleged ground that the powdered bark lost some of its alkaloidal richness by keeping. At present, however, the system of crushing bark has become universal in Java and at the Amsterdam auctions nearly all the manufacturing barks are now offered in that condition, and the pharmaceutical barks in quills. Since 1874 it has been customary to sort the Java quill bark in two classes, according to length.—*Indische Mercur.*

PLANTING IN FIJI.

Suva, Jan. 26th.—Of late climatic possibilities and probabilities have furnished the chief topic of conversation. Throughout the closing month of last year we had a continuous downpour of rain, unseasonable as it was unwelcome to our cane-growers, thoroughly saturating and soddening the soil and all else capable of absorbing moisture. During the past month we have had hot northerly winds, with a blazing sun right overhead—a combination resulting in an oppressive heat exceeding anything before experienced within the memory of the traditional oldest inhabitant. A change for the better has, however, taken place within the last day or two, during which a deliciously cool S. E. wind has been blowing. Early in the month the Union S. S. Company steamer "Waiui" cleared for Auckland, via Tonga, having shipped at Laucala Bay 400 tons of sugar produce of the O. S. R. Company's Nausori mill. The "Omapere," leaving for the same port on the 15th inst., carried away close on 370 tons, shipped from the Narres and Rewa mills. The "Pukaki" on arrival will load up all sugars offering, probably going round to the Bs for the balance of Rarawai mill produce, there

after taking departure for Auckland on or about 1st proximo. The "Taupo" will take up the Pukaki's trade, and getting despatch on the 30th inst. will carry some good parcels from Mango and Penang mills. The Rarawai mill will be at work for another fortnight or three weeks, but on the other side of the island all the mills have closed for the season. The Penang, Erlington, and Tavini Estates will, I understand, continue crushing operations into March, unless stopped by unfavourable weather. Our local papers contain a notice that the Rewa Sugar Company's estates, known as Koronivia and Ului Calia, together with mill machinery and all plant thereto belonging, are to be sold in your city on the 5th prox. Messrs J. C. Smith and Co. are the successful tenderers for the purchase of copra tax produce during the current year. The contract price for deliveries in Levuka is reported to be £7 7s. 6d. per ton. The Government are now calling for special tenders for the purchase of copra made on Rotumua Island. During the past month the firms seeking cargo for the Juno gave up to £8 per ton for approved copra, but the ruling price in open market can now be quoted at £7 5s., as with the departure of loading vessels keen competition to purchase ceased. During the month close on 100 tons copra has been shipped per steamers to Auckland and Sydney. Owing to unfavourable weather when the "Tenderden" was loading fruit at Suva on the 15th inst. a large number of the Musquito fleet, carrying from the adjacent districts, Rewa and Navua, failed to reach prior to the steamer's departure, thus leaving something over 5,000 bunches of bananas on the exporters' hands. As it was she carried away 16,700 bunches a boat owned and sailed by some Santo Islanders was spozed and sunk, one of the unfortunates on board.ailing to reach the shore by swimming.—*Australasian.*

A PROFESSIONAL GOLD MINER who has visited the Waragoda pits and washings, declares that he could make them "pay"; but enterprise here and elsewhere will be stopped now until it is seen how the Government legislation is shaped.

"BLENDED" CEYLON TEA.—In the list of trade marks applied for, as given in the *Grocer* of 22nd Feb., is one by Messrs. Game, Harrison & Lerner, tea and coffee merchants, London, containing the words "The Westwood Blend, composed principally of Finest Ceylon Tea as imported direct from gardens." The words which we have italicized are in very small letters, and are over-printed with a floral design, so as to be almost entirely obliterated. We are certainly surprised at a wellknown firm like the one mentioned allowing such a label to go forth with its name attached to it.

GREEN TEAS.—"S. T." writes to the local "Times" in correction of the "expert" who gave us certain information, as follows:—

The "limited consumption" of Shanghai greens he talks about, amounted last season to over 22 million lb. of which the U. K. took 7½ millions and the U. S. of A. 14½ million lb. "Japan" greens are called "uncolored" in America, but they are not really entirely pure tea, though the coloring matter is in such small proportions that it is, hardly noticeable either in the dry leaf or by sediment in the cup. Shanghai greens, especially Ping Sueys, on the other hand, are much more highly colored and faced, and clearly show an expert by the color of the dry leaf and sediment in cup that they are so. The coarser the leaf the greater amount of coloring and facing. As Ceylon has not taken to coloring her teas yet and I hope she never may, I do not see where the danger lies of planters producing too much Green Tea "resembling Shanghai Greens." It will be a good number of years before Ceylon can produce 64 million lb. of Green Tea and Oolong, which was about the total quantity of these classes shipped from China and Japan to the U. S. and U. K. during the season just closed.

BASEL MISSION CANNANORE CLOTH IN PERAK is thus noticed in the report on Kinta in the *Perak Government Gazette* :—"Some striped Cannanore cloth I ordered from the Basel Mission, for the convicts, has been made up. I consider it a great success; the colours are yellow and dark grey—almost black. It is cheap, and very strong, and will wear much longer than the drill hitherto used. It being so different to any material worn by natives will render the escape of convicts more difficult."

TEA IN THE UNITED STATES does not seem to be gaining in favour as coffee does. The figures for 11 months of 1889 show that the value of coffee imported had increased from \$42,252,000 in 1884 to \$72,189,000 in 1889. The value of tea imported in the same period had gone down from \$13,000,000 in 1884 and \$14,179,000 in 1886 to \$10,658,000 last year. Let us hope that the operations of the Ceylon Company may lead to a better appreciation of tea in the States.

COFFEE AT THE STRAITS.—A correspondent sends word that Mr. C. H. de R. Hensler, a pioneer Liberian coffee planter in the Straits, is now on tour in the Malay Peninsula looking out for land likely to suit the cultivation of staple produce articles. He finds it is said several parts of Perak to rank as high as the famous coffee districts in Ceylon, and is negotiating with the Government of that protected State for a concession of ten thousand acres to be worked by a company with a capital of one hundred thousand pounds sterling.—*Straits Times* March 11th.

MAHOUSA TEA CO., LD.—On the 26th February there was registered a further company connected with Ceylon, the Mahousa Tea Company Limited. It hardly seemed likely to me from the name, which sounded strange to my ears, that this undertaking had reference to your island, but Mr. A. Bryans, of Messrs. Buchanan & Co., of 9 Fenchurch Avenue, one of the directors, has told me that Mahousa is the native name for the Mousakelle estate situate in the Kelebokka Valley, which estate it is by the articles of association proposed to work. Mr. Bryans, on my asking him to give me a prospectus of this new company, told me that he could not do so for the very good and sufficient reason that one had not been prepared or printed :—"Indeed," he said to me, "we do not care that the Company should have any more publicity than was given to it by the necessary act of registration. It is quite a private affair. The Company consists exclusively of the present proprietors of the estate, whose sole object is to protect their interests by availing themselves of the law to limit their liability. I can therefore give you no particulars, nor, could I do so, would they be possessed of the least public interest." The following are the names of the parties to the deed of registration &c. &c. as annexed in the financial papers :—

MAHOUSA TEA COMPANY, LIMITED.

This Company was registered on the 26th ultimo, with a capital of £18,000, in 45 shares, to purchase the Mousakelle estate, situate in Kelebokka Valley, Dumbura District, Ceylon, and to cultivate tea, coffee, cinchona, and other produce. The subscribers are :—

	Shares.
J. H. Wilson, 14, Lexham-gardens, merchant	1
*A. Bryans, 9, Fenchurch-avenue, merchant	1
P. Robertson Ross 11, Sloane-gardens, S. W. ...	1
*W. L. Watson, 7, Wetherley-gardens, S.W.	1
W. T. D. Blackhall, 35, Nicholas-lane, bank manager ...	1
*S. Boulnois, Army and Navy Club	1
A.Y. Buchanan, 4, Taunton-place, Regent's-park, wharfinger ...	1

The number of directors is not to be less than 3, nor more than 5; qualification, 100 shares; the first are the subscribers denoted by an asterisk; remuneration, £2 2s each per meeting. Solicitors, Messrs. Oehme, Summersays and Co., Gresham-house.

—London Cor.

A DUTY ON EXPORTS OF COFFEE.—The Congress assembled at San Salvador has issued a decree that from the 26th ultimo a duty of \$1 per quintal be imposed on all coffee exported during one year, the proceeds to be used in the reconstruction of the national palace.—*American Grocer*.

SENEGAL CAOUTCHOUC.—In a French report on the products of Senegal it is stated that the average annual production of caoutchouc in Cazamance is 50,000 kilogs, but in 1889 its collection was neglected. The southern rivers produce annually (including the Bissagos) about 400,000 kilogs. to 500,000 kilogs., according to the years. The price of ordinary caoutchouc is in Cazamance 3 francs for best quality, and in France 3 francs 75. Superior caoutchouc, best quality, fetches 4 francs 25 in Cazamance, and 5 francs in France. Inferior caoutchouc is sold according to its purity. Business is done in the presence of the article, because it is of an irregular quality mixed with sand and foreign substances. Liverpool, Bordeaux, and Marseilles are the principal markets. The export duty levied in Senegal on this article is about 18 centimes per kilog., whilst the rate of freight to France is given at 60 francs per 1000 kilogs.—*Electrical Trades Journal*.

THE INDIAN CINCHONA COMPANIES.—When gold mining was abandoned by some of the Wynaad Companies, they directed their attention to agricultural pursuits, and the cultivation of the cinchona bark was largely pursued. Devala Moyer (which is still continuing to mine with fair prospects of success) has about 130,000 trees, and should be able to deliver some 40,000 lb. per annum, but the quantity is too small to greatly affect the receipts. The Tambrachery and Wentworth Companies are both large producers, and the rise present and anticipated is of great importance to them. The cultivation of bark has not always been attended with success. Glenrock has done something in this way, and Indian Consolidated has cinchona as one of the strings to its bow, which must not be omitted in any fair estimate of its assets. It has about 120,000 trees on its Wynaad estate, averaging from 5 to 14 feet in height, some of which are eight or nine years old. We do not wish to lay too much stress on the improvement that has taken place in the price of cinchona bark but we think it right to keep our readers informed of the fact, and also that it constitutes one of the assets of the various Companies we have named.—*Madras Mail*.

SALE OF WEDMORE QUININE WORKS.—On Monday, at the Bromley County Court, an action was brought against Mr. Martin J. Dickens by Mr. William Tar for the recovery of £21 5s., being half the commission on the sale of the Wedmore Quinine Works. The plaintiff stated that the vendors of the quinine works, Wedmore, instructed him in July last to endeavour to find a purchaser for the works, and a commission note was given to him by Mr. Cooke, one of the vendors. When he was away one day Mr. Henry Podger came to see him, and he was informed of the visit. Mr. Dickens came to see witnesses last September, and asked the name of the vendor. Witness informed Mr. Dickens that if he gave him any assistance in the matter he should expect to share the commission, and this the defendant promised. Witness then gave Mr. Dickens a note of introduction to the vendors, and under a commission note received Mr. Dickens sold the works to Mr. Henry Podger on October 16th, the price realised being £1,650. The commission on this amount was £42 10s., and on plaintiff applying to defendant for his half he denied having promised him anything. Cross-examined: Witness had received £25 from each of the vendors, Mr. Robertson and Mr. Cooke. Mr. Cooke said Mr. Dickens was introduced to him by plaintiff. For the defence it was contended there was no promise, the defendant's sole object in seeing the plaintiff being in respect to the mortgage. Judgment was given for the defendant with costs.—*Chemist and Druggist, March 8th.*

STAPLE EXPORTS OF CEYLON FOR TEN YEARS.

In reality the table compiled by the Chamber of Commerce is only for the two ports of Colombo and Galle; but as a matter of fact from these alone are our principal products sent beyond the seas. At the same time there will always be a difference between the Customs' and the Chamber's returns for the calendar years, for this reason. The Customs enters in its export return every shipment as it passes on board vessels in the Harbour and on 31st December has in its total a good deal of produce that has not left our harbour; while the Chamber of Commerce makes no entry in its export return until the vessel has cleared and left our shores.

In analysing the present Export return there is not much which has not been the subject of remark in connection with the old season's returns: coffee has gone down from 601,253 cwt. 'plantation' kind in 1880 to 83,300 cwt. last year or not one-seventh; while native coffee has gone down in the same time, from 47,554 cwt. to about one-tenth in 4,782 cwt. Cinchona Bark on the other hand at the opening of the decade gave only 1,151,102 lb. for export, but rose to 14,838,402 lb. in 1886, and went down last year to 9,283,729 lb. Tea is wonderful in its steady rise in ten years from 114,845 lb. to 34,048,085 lb. Cocoa too in a smaller way shews a wonderfully steady rate of increase, the only check being in 1888. If counted in lb. like tea the export of cocoa would look quite respectable at over 2 million lb. Cardamoms in its progressive rise from 10,484 lb. to 361,224 lb. is very satisfactory. Cinnamon we all hope—in "chips" at least—will begin to show a falling-off, although hitherto, in both bales and chips, the figures have been shewing steady development. Coconut oil has seen many vicissitudes between the exports—347,208 cwt. in 1880, 387,817 cwt. in 1884, and 356,576 cwt. in 1889. But the other products of the Coco Palm have come to the front in Copra which rose in exports from 24,711 cwt. in 1880 to a maximum of 189,306 cwt. in 1884 only to fall to 138,578 cwt. in 1888 and to the very poor return of 38,384 cwt. last year. Its place has however to some extent been taken by "Coconut Poonac," the shipments of which have gone on progressively from 26,456 cwt. in 1884 to 136,237 cwt. last year. A new heading in the statement of recent years is "Coco-nuts" of which nearly 10½ millions were sent away in 1887, last year the export being a little over 5 millions. Plumbago has developed wonderfully of recent years, the export having been 208,643 cwt. in 1880 and keeping steadily at between that and 270,000 cwt. until last year when suddenly, the enormous export of 475,516 cwt. took place. The utmost activity in this branch of industry still continues and the present year also promises well in respect of Coconut Products. Next in the list comes some of these under the heading Coir (Rope, Yarn and Fibre) in which it will be seen the trade for the ten years has been, on the whole, a steadily progressive one:—70,000 cwt. of all three shipped in 1880 contrasting with over 120,000 cwt. last year. Ebony on the other hand has woefully fallen off from an export of 50,000 cwt. to less than 4,000. Other minor products do not show much that is noteworthy, save for the enormous development of the trade in Essential Oils (Citronella and Cinnamon) from 250,000 ounces in 1880 to about 10½ million ounces last year.

We recur to the Return compiled and published by the Chamber of Commerce and to enable our criticism and comparisons to be clearly understood, we reprint the table once more here:—

EXPORTS OF CEYLON PRODUCE from COLOMBO AND GALLE Annually during the past TEN YEARS. Compiled as from 1st JANUARY to 31st DECEMBER in each year.

C. E. H. SYMONS, Secretary.

Chamber of Commerce, Colombo 20th March 1890.

To afford comparison in respect of our principal staples, we repeat the figures for exports for four years as given by the Customs Department:—

STAPLE EXPORTS:

ACCORDING TO CUSTOMS ACCOUNTS.

	Tea	Cocoa	Cardamoms	Cinchona.
	lb.	cwt.	lb.	lb.
1880 ...	162,575½	121	17,412	1,161,189
1881 ...	343,798	283	16,607	1,314,554
1882 ...	697,268	864	20,959	4,655,944
1883 ...	1,665,768	3,376	38,688	7,489,005
1884 ...	2,392,973	9,241	77,164	11,865,230
1885 ...	4,372,722	7,466	184,142	13,736,171
1886 ...	7,849,888	13,056	238,947	14,675,663
1887 ...	13,834,701	17,460	384,015	13,113,067
1888 ...	23,820,724	12,231	282,595	12,499,949
1889 ...	34,345,852	18,849	465,944	9,455,661

The discrepancy is due to the fact that the Customs enters each shipment as exported; while the Chamber only enters the totals for each vessel as it clears out of port. To afford a closer comparison, we give the total exports for 1889 according to the Customs accounts in order to compare with the Chamber's return:—

CEYLON PRODUCTS EXPORTED DURING 1889

(According to Customs Accounts.)

COFFEE Plantation	cwt. 80,289	Coconuts	No. 5,409,982
do Native	" 8,896	Plumbago	cwt. 486,138
do Total	" 89,985	Coir Rope	" 10,321

do Chips	" 501,102	Kitool Fibre	" 3,075
Coconut Oil	cwt. 379,936	Citronella Oil	oz. 10,816,812
Copra	" 51,960	Cinnamon Oil	" 32,004
Coconut Poonac	" 138,924		

We have now an interesting comparison to offer in order to show the progress made in the last two years in our export trade. For this purpose we have turned the exports for 1888 and 1889 into "shipping tons" and the totals indicate the extent of the demand on freight and tonnage of all the products specified during the two years given:—

Product.	Quantity to Shipping ton.	Total Shipping tons	
		1888	1889.
Coffee ...	cwt. 14	9,976	6,291
Cinchona Bark ...	lb. 1,750*	7,255	5,304
Tea ...	lb. 1,000*	24,381	34,048
Cardamoms ...	lb. 1,000*	287	361
Cocoa ...	cwt. 14	939	1,361
Cinnamon Chips... lb.	1,200	1,996	2,376
do Bales ... lb.	800		
Plumbago ...	cwt. 20	11,286	23,775

Cinnamon Oil ...	oz. 100,334	7,891	7,891
Tobacco ...	cwt.	50,000

We next give estimate of value for the year's Exports as follows:—

Detailed Estimates for the Current Year's Exports:—

Season 1890.—Probable Shipment of Staple Exports.

	Quantity.	Value
Tea	43,000,000 lb. at 60 cents	R25,800,000
Coffee	100,000 cwt. at R35	6,500,000
Cinchona Bark	7,000,000 lb. at 20 cents	1,400,000
Cocoa	20,000 cwt. at R45	960,000
Cardamoms	300,000 lb. at 80 cents	240,000
Coconut Oil	300,000 cwt. at R14	4,200,000
do Copra	40,000 cwt. at R7½	300,000
Coconut Poonac	120,000 cwt. at R4	480,000
Coconut	6,000,000 No. at 2½ cents	150,000
Cinnamon	2,000,000 lb. at 50 cents	1,000,000
do chips	200,000 lb. at 18 cents	36,000
Plumbago	400,000 cwt. R10	4,000,000
Coir of all kinds	120,000 cwt. at R8½	1,020,000
Ebony	5,000 cwt. at R5	25,000
Deer Horns	2,000 cwt. at R40	80,000
Sapan Wood	2,000 cwt. at R30	60,000
Kitool Fibre	3,000 cwt. at R35	105,000
Orchella Weed	600 cwt. at R50	30,000
Essential Oils	6 millions at 5 cents	300,000
Tobacco	50,000 cwt. at R40	2,000,000

Total...R48,686,000

NOTES ON PRODUCE AND FINANCE.

The letter of "Sigma" in our last issue deserves the careful consideration of all those interested in tea. There is no need to demonstrate or insist in the necessity for more union. Individual members of the industry are always willing to admit that union is most desirable, but they seldom go beyond it. There are men of "light and leading" to be found amongst the numbers connected with the industry, and if some of them would meet together and shape a scheme for union of a practical kind, some good would result. It is useless to bark, as our correspondent, "Kumaon," does this week, against the selfishness which prevents, or is likely to prevent, combination. If there has been too much of this individualism in the past necessity will teach the wisdom of a fresh start for the future. Who will take the lead in inaugurating a new policy upon the lines indicated by "Sigma"?

The bulking question is again to the fore, and there are complaints about irregular bulking on the part of the warehouse keepers. The members of the Indian Tea Districts' Association have under consideration the question of responsibilities of warehousemen for loss caused by contracts repudiated on the ground of imperfect bulking.

The movement for converting the French nation into tea drinkers is making headway. The Ceylon planters are doing their best to push Ceylon teas,

and those who have charge of the interests of Indian tea producers are also earnestly pushing those interests. It is satisfactory to learn that the sale of Indian tea in France is on the increase, and it is to be hoped that the movement will not lack support. Indian tea growers often express surprise at the growth of the Ceylon tea trade, but fail to reflect on the fact that those interested in the latter industry are keen enough to see the advantage to be reaped by constant effort to bring their wares to the notice of the public, and are quite willing to contribute freely to bring this about.

The increased landings of tea, as shown in the Board of Trade Returns for last month, are chiefly from India and Ceylon, but there is also an increase in those from China. The quantity taken for consumption is, however, only 13,000,000 lb., against 14,429,000 lb., while wine and tobacco show an increased consumption as well as an increased import. The stock of tea in the bonded warehouses at the end of the month is given as 123,527,810 lb. as compared with 113,715,118 lb., and that of tobacco 125,521,136 lb. compared with 107,755,000 lb.

The tea growers of China are in despair. The returns from the Poochow district are especially troubled, for the export of tea again shows a further shrinkage. The Governor of Formosa has resolved to start a model plantation, and make tea after the Indian fashion, under the supervision of an expert from Assam. Possibly this idea will be imitated, although the conservatism of the Flowery Land will be slow to follow another's lead in the matter of turning out their own pet product for market.

The much-abused coffee-drinker may pluck up heart of grace. According to the *Lancet*, Dr. Lüderitz has recently made a number of observations on the destructive power of coffee upon various microbes. He found that the organisms all died in a longer or shorter period—*e. g.*, in one series of experiments anthrax bacilli were destroyed in three hours, anthrax spores in four weeks, cholera bacilli in four hours, and the streptococcus of erysipelas in one day. It was, however, remarkable that good coffee and bad coffee produced precisely similar effects. He believes that, as previous observers have suggested, the antiseptic effect of coffee does not depend on the caffeine it contains, but on the empyreumatic oils developed by roasting.

At the moment there are several facts to prove that the position of coffee is favourable to importers, but the most striking of all, says the *Grocer*, is the official estimate of the Government crop of Java coffee, which gives the probable outturn for this season at only 187,000 piculs, in contrast with an actual yield of 585,000 piculs last year. This must make a great difference in the quantity that will be available for the Dutch Company's public sales as the season advances, for the stocks in reserve are anything but excessive, and owing to the consequent diminution in the supplies of favourite coffees on the Continent, an improved demand from shippers here is likely to be experienced for that quarter. Should such a change as the above really take place, the total supply in London will be further trenched upon, and instead of prices receding, they may continue to harden as they have done since the opening of the year, being for the commoner sorts 2s to 4s per cwt. dearer than they were then. The consignments of the first portion of the new season's crops of plantation Ceylon, other East India, Jamaica, and Costa Rica, &c., lately put forward, have, so far, afforded entire satisfaction to the dealers as well as the exporters, because the quality has been superior to the average of preceding years, and almost fancy prices have been obtainable, particularly when fine bold, blue colour, and close-made peaberry kinds have ranged from about 110s to 120s, and to even 130s, or more, unroasted and in bond. At such a high rate of prime cost, equal to 1s 4d to 1s 6d per lb. net duty paid and roasted, without allowing a single fraction for the dealers' or retailers' profit, it is no wonder that the consumption of the article does not progress as it should do in this country; neither is it surprising that the dealers complain of the difficulties and disadvantages they labour under in trying to push the sale of coffee, when

it has to compete with the cheapness of tea and chicory, to say nothing of certain forms of adulteration, and pay a Customs impost of 14s per cwt. besides.—*H. and C. Mail*

THE SUGGESTION OF A TEA PRODUCERS' UNION.

To the Editor of the *Home and Colonial Mail*.

Sir,—Why not a Producers' Union! Well, sir, there are reasons why not, but these have nothing to do with the "sweet reasonableness" of your correspondent's proposal. It is mainly because tea planters are not given to combination. They care nought for general interests; they have one idea, to make a good crop, and to realize good prices for their own produce, and to leave their neighbours to the tender mercies of one who shall be nameless. A combination of tea growers is a capital idea, but it will never be anything else. The tea industry, so use a phrase now so commonly applied, is peculiarly constituted. I have read former correspondence in your useful paper bordering upon this subject, and abler pens than mine have, I think, pointed out the difficulty attending attempts at combination amongst tea producers. Rival interests, sir. It is of no use binking it. The big companies bar the way. For real undiluted selfishness some people I know who are in tea stand pre-eminent. Some of these large tea companies are under the control of men who do not recognise any other interests in tea but those of their own concerns, and so long as they have the power there will be no fusion for the general good. The notion of a Producers' Union is a sound one; but when it comes to the detail of it some will pull one way and some another, and in the desire to look after "number one" all other objects will be forgotten. "Individualism," as your correspondent calls it, will die very hard in all commercial circles; but I think that if ever we approach to that happy state of things which sanguine Socialists picture, it will be tea garden proprietors who will make the last stand on the threshold of the new era and raise their old cry, and wave the tattered banner of "perish everybody else so long as my teas and my interests are first and foremost. This is considered smart and clever in business but it is fatal to unity of interests as well as grossly impolitic. The man who sets out with the idea welding the rival tea interests into one harmonious whole for the general good of producers will need to be made of something more than human clay. I am, sir, your obedient servant, KUMAON.

RUBBER.—There are over 120 India-rubber manufacturers in the United States, employing 15,000 hands, and producing annually 280,000 tons of goods, valued at 260,000,000 dols.—*Electrical Trades Journal*.

THE ORANGES OF THE KASI HILLS.—Few people in Bengal have any idea of the profusion in which oranges grow on the southern slopes of the Kasi Hills and elsewhere in Assam. In computing a harvest the oranges, it appears, are neither weighed nor measured, but are actually counted. We are thus informed that the number imported last year into Bengal was 37,053,960, valued at one lakh and eighty-three thousand rupees. Yet it was a bad year; for more than 75½ million oranges came down the river the year before, and more than 40 millions three years ago.—*Pioneer*, March 24th.

THE PRODUCTION OF IVORY.—There are annually killed in Africa a minimum of 65,000 elephants, yielding a production of a quantity of raw ivory, the selling price of which is some £850,000. This quantity is shipped to various parts of the world—to the American, the European, and the Asian markets. A large quantity is, however, kept by the native princes of Africa, who are very fond of—and as a rule, very good judges of—ivory. The production out of Africa is only insignificant, and India, Ceylon, and Sumatra together produce only some 20,000 kilogs. per year. India is the largest consumer of ivory, and China is also a good market.—*Electrical Trades Journal*.

PROFITS OF INDIAN TEA COMPANIES.

We think the following table from the *Home and Colonial Mail* shows good reason for the Indian tea industry being well supported. The highest average dividend recorded is as good as 13½ per cent, while the lowest is close on 4 per cent. :-

	Average for 9 yrs. %ct.

THE BOTANICAL LABORATORY IN THE ROYAL GARDENS, PERADENIYA, CEYLON.

The attention of the readers of *Nature* has been drawn more than once (vol. xxxi. p. 460, vol. xxxiv. p. 127) to the opportunities which are before botanists for the study of plants other than those of our own flora. But since the latter of these articles appeared, a step has been taken which will justify a return once more to this important subject.

It is certainly one of the most healthy signs of the present time that our younger botanists desire not merely to pore over minute details of microscopical structure in the laboratory at home, but to become personally acquainted with plants in the open. When the somewhat sudden reversion occurred some fifteen years ago, from taxonomy, as an academic study, to the more detailed examination of the tissues of plants in the laboratory, and the study of their functions, those who took a large view of the progress of the science must have seen with regret that the change, however valuable in itself, brought with it a new danger. Those who as students were first introduced to plants as subjects of microscopic study ran the risk of failing to appreciate the importance of external form: they acquired a knowledge of the minute structural details of certain plants, but did not acquire a strong grasp of the external characters of plants as a whole. But the pendulum which thus swung rapidly over to an extreme position is now returning to the mean. While duly appreciating the value of microscopic examination, the younger botanists are awake to the advantage, or even the necessity, of a wide knowledge of plants. The whole area

of facts upon which those who are now engaged in teaching draw in the course of their lectures is much wider than it was ten years ago, and the extension has, perhaps, been most marked in the province of external morphology.

This being so, there will be no need to press upon the men who are starting upon a career as botanists the importance of a visit to the tropics: they will look upon the collections in our Botanic Gardens, which they are hardly allowed to touch, as only a temporary substitute for a tropical jungle, where they may cut down plants as they please, in order to obtain specimens illustrating nature or developmental characters. Moreover, those characters of a tropical flora which are the most striking and characteristic are often those which must remain entirely unrepresented in our glass-houses at home. An expedition to the tropics should, in fact, become a recognized item in the programme of preparation for a career as a teacher of botany.

The advantages offered by the Royal Gardens at Peradeniya have already been pointed out in *Nature* (vol. xxxiv. p. 127); but since that article was written steps have been taken by a Committee of the British Association to add to them. Backed by a grant of money, they have undertaken the establishment of a permanent laboratory in which visitors may carry on their work. A room has been set apart for this purpose in the official bungalow by the directorate of the Royal Garden. It has every advantage of position, being placed centrally in the garden, and within easy reach of the herbarium, &c.; while, since it is under the same roof as the Director's office, visitors would have the great advantage of the presence of Dr. Trimen himself as a referee in recognition of the plants of the rich native flora. In this room are to be found such apparatus and reagents as are ordinarily required for laboratory work, and steps are being taken to add other facilities.

The mere mention of these facts will probably suffice to attract those who were not previously aware of them. The chief deterrent will be the cost of the journey. It has already been stated that £200 to £250 will suffice for all expenses of an expedition of six months' duration, while if two club together the individual cost would be considerably smaller. Though the Committee of the British Association have no power to use the money entrusted to them as a personal grant, still it is well known that there are sources from which such grants may be obtained in order to assist those who are engaged on a definite line of research. Bearing all these facts in mind, the value of such an expedition as that to Peradeniya cannot be too strongly urged on those who are about to enter definitely on a career as professed botanists. The widening of view, and opportunity for research, which any man of originality would obtain by it would amply repay him for his expenditure of time and money. Applications for the use of the laboratory, which is at present vacant, should be made to Prof. Bower (University Glasgow), who is the secretary to the Committee.—*Nature*, March 13th.

CEYLON TEA: LONDON BROKERS' REPORTS FOR THE PAST YEAR.

This mail has brought us a copy of Messrs. Wilson, Smithett & Co.'s very valuable Annual Report entitled "Ceylon Tea Memoranda for 1889" and which is dated March 1890. It also brings Messrs. Geo. White & Co.'s "Annual India, Ceylon and Java Tea Report" containing much useful information especially in the elaborate statistics. Pending the reprinting of the former in full and considerable extracts from the latter, we may notice today a few of the salient points of special interest to Ceylon tea planters. Considering that Ceylon tea offered in auction in London during 1889 showed an increase of 50 per cent over 1888, Messrs. Wilson, Smithett & Co. think the reduction of the average for the year to 10½d per lb. from 11½d in 1888, a matter which can be viewed with equanimity and still more the fall from 1s 1d in

1887 when the imports were only a third of those last year. They point out that the development of the Ceylon tea trade stands unrivalled, seeing that virtually it only began in 1881 with an export of 300,000 lb. and that in nine years this has grown to 33,000,000 lb. representing a value of £1,500,000. India with the vast acreage at its disposal, can show no such progress; for it took her twenty years to attain the same position as a tea exporter. It is noticed that Ceylon teas are becoming appreciated on the Continent and orders from Russia especially for high-grown pekoes have given increased competition to the London sales. Messrs. Wilson, Smithett & Co. do not much believe in "green teas," the demand at a good price being limited, and the Americans paying poor rates for their green teas as a rule. The Brokers are more in favour of true Oologs of a quality like the Formosa Oologs.

In the list of estates with total quantity of tea sold and averages realized in 1889 (as compared with 188) Messrs. Wilson, Smithett & Co. have this year confined the marks given to all selling 20,000 lb. or upwards. They have also divided the list into four groups:—Over 200,000 lb.; 100,000 lb. to 200,000 lb.; 50,000 lb. to 100,000 lb.; and 20,000 lb. to 50,000 lb. They indicate the altitude as far as possible by initial letters. The first mark in this list is "Wallah" which sold last year 342,000 lb. about 50 per cent more than in 1888 with an increase of 10 per cent in the average or 1s 1½d. K. A. W. sold 533,000 lb. and Mariawatte 480,000 lb. or over the million between them and at the same average of 11d. Glenugie heads the second group with 129,000 lb. averaging 1s 2½d. Goatfell heads the third group with 72,000 lb. average 1s 3½d. At the top of the fourth group comes Hoolankanda with 22,000 lb. averaging 1s 9d by far the highest in the whole record; Portswood follows with 43,000 lb. at 1s 4½d against 1s 3½d in 1888; and then come both Alnwick and Sheen with the same average of 1s 3½d, the quantities being 42,000 and 39,000 lb. respectively.

The average obtained for the different groups of districts is of interest: the principal change being in Hewaheta which stood first last year, but is now down to fifth.

Messrs. Geo. White & Co. in their Report give an estimate of the requirements and shipments for "the coming season"—that is 1st July 1890 to 30th June 1891:—

Required for Home Consumption	190,000,000 lb.
do do Export	35,000,000 lb.
	225,000,000 lb.
India will send, say	110,000,000 lb.
Ceylon do	45,000,000 lb.
Java &c. do	6,000,000 lb.
Leaving China to supply	95,000,000 lb.
	225,000,000 lb.

This firm would like the Ceylon "tea season" for crop estimates and export figures altered to correspond with that of India. Unfortunately this has not been done.

CINNAMON AND COCONUTS.

VEYANGODA, 23rd January, 1890.

In spite of the very dry weather we are having, Cinnamon peels fairly well. As is to be expected, the more mature sticks do not peel; indeed these peel only at intervals and during very favourable weather as a rule. Some Planters peel all during the dry season and professedly only coarse sticks. The reason they adduce for the practice is that unless they do this, they will have no Cinnamon for the following year, as coppicing helps shoots. This is hardly correct.

If you follow the peelers into the field during the dry season you will find that barely 5 per cent. of the coarse sticks peel. The rest are all tested with the catty. The wounds thus caused gape till the wet weather and growing season come round and, will not, as under favourable circumstances, cicatrise and be healed. Very often they bleed freely. The result is that such sticks are checked in growth, the leaves then turn yellow, and as often as not they are never fit for peeling again, and have to be removed by the pruners. Again, careful observation will show that the shoots thrown out during the dry season are generally the thin and sickly ones that are removed by the pruners. Forced cuttings during the annual droughts are, I think, productive of more loss and harm than gain. Among Tea Planters the style of picking that is most profitable is a vexed question. As in everything else, a middle course is said to be the best, and medium picking finds the largest number of adherents. Among Cinnamon Planters, too, whether fine or coarse cutting is the best is not quiet settled. The adherents of each system have much to say in favour of what they practise. I have given the subject a good deal of attention, and am inclined to think medium cutting better than fine, even though the Cinnamon resulting from the latter system fetches dazlingly high prices. This more especially, when seasons cannot be calculated on. Making fancy Cinnamon occupies much time, and unless you have a very large force of peelers, the season is partially lost. Delay in harvesting your crop means, apart from having so much capital lying useless, your Cinnamon growing coarse. The result is that the coarse qualities predominate, and that what is gained in the higher prices of the finer Cinnamon is lost in the larger quantity of the coarse qualities that is turned out.

Coconuts always run up in price as the smaller crops are harvested, and the balance is thus maintained. The crops of the S. W. months are generally the large crops. This is easily understood, as the S. W. rains follow the trying drought at the beginning of the year. During this period the trees receive a very severe shock to their system, and in obedience to a law of Nature make a violent effort at reproduction. These shocks to fruit-bearing trees are sometimes artificially produced, as by branch and root pruning. The latter is too severe for a tropical climate, and even branch pruning can be overdone. However beneficial a stirring of the soil may be, I am averse to the frequent stirrings when perennials are cultivated, owing to the severe shock the trees receive. The prices of Coconuts are higher now than they have been for many a long day, and Coconut Planters are sorry that they have so little crop to benefit by them. I have heard of the price of nuts as R37-50. This may be apocryphal, but R35 to 36 can be obtained now for 1,000.

A correspondent in the *Observer* in sending a cutting to that paper on Coconut Butter hazards the guess that possibly this is the stuff that is manufactured here. That desiccated coconut and not butter is manufactured here is no secret. The only secret about the Mills is the mode of manufacture, and that for obvious reasons. It is rumoured that the business may be extended, and that new appliances for desiccating will be used. What with competition, the Mills, I fear, cannot get sufficient nuts for their wants.—Local "Examiner."

PRESERVATION OF LEATHER.—Californian papers announce the discovery of a substance which has an extraordinary effect upon leather, rendering it waterproof, pliable, and almost indestructible. The discovery is alleged to have been made in the laboratory of the State University of California. Some combination of fatty matter and sulphur is hinted at as the ingredient which is to revolutionise the leather trade, preserve shoes, and turn old boots into new ones. Assuming a certain amount of truth in the statement which reaches us, it would seem that our Californian friends have it upon something like our Gishurstine.—*Gardeners' Chronicle.*

Peradenia, April 23rd, 13.

To His Excellency the Governor.

Sir,—The great encouragement I have received from your Excellency, and the authorities of your wise government has impressed me with more than usual anxiety to forward any object under your direction, that may come within the reach of my occupation, or capacity; which united to the attention I am happy to know your Excellency pays the Science of Botany, I hope will plead sufficient apology for my presumption, in humbly submitting the following to your Excellency's consideration.

During the time I have spent upon this rich Island my researches have been rewarded with so much success that I have sent to England 45 and have in hand 22, total 67, different living specimens of orchideæ plants, and every Tour the more convinces me that those already found convey but an imperfect idea of those existing yet to be discovered. Many of the above were not amongst the drawings, or specimens, at the Botanic Garden, Peradenia, (though some were found within a few miles of that place) and am sorry to say some will probably be lost to the collection there. I have personally taken and sent specimens to that Establishment, which by some unaccountable negligence have neither been drawn, or otherwise preserved, and the scarcity of the plants has sometimes compelled me to rest satisfied with my own written descriptions of them; neither is it convenient, or suitable, to the economy of my plans to do further justice to them in a jungle where I am often exposed to the greatest possible difficulties. Will your Excellency therefore be pleased to consent to the plants been speedily drawn, (which will be chiefly orchideæ) that I send to the Botanic Garden, Peradenia; and direct that such attention be paid to it as may correspond with your Excellency's own inclination when the most powerful exertion on my part shall be used to forward from all parts of the Island I may visit, such plants that are rare, or will prove an addition to the number already discovered. I further most humbly beg your Excellency will grant me a copy from the Botanic Garden, where the plant is scarce or difficult to be preserved. This latter is more than I would presume to ask (how-

ever greatly it would benefit me), but I have seen too often with much sorrow, the Draftsman on the establishment wanting better employ.

It will doubtless be known to your Excellency, that my occupation on this Island, cannot be maintained without considerable expense to my enthusiastic employer J. Knight Esq., whose motive I believe in sending me here, was more the advancement of Science than speculative emolument, But I hope your Excellency will admit, it is due from me as his servant, to solicit your Excellency's protection to him against the risk of sacrifice in capital, as far as it is practicable on this Island, and wise in the opinion of your Excellency's government. The above object will be greatly secured by prohibiting the exportation to England, (from the Royal Botanic Garden, Peradenia) of those plants in a live state. I send these for the above purposes, collected by my own individual exertion. I do not even remotely desire to monopolize the privilege of sending home living specimens, but to have the merit (if I may be allowed the expression,) of making any new discovery, and securing to my employer the benefit of their circulation at home if possible, to compensate him for his outlay. Will it, moreover, be pleasing to your Excellency to direct, that the contributions I make to the Botanic Garden collection of drawings, or Hortus Siccus, be acknowledged on affixed labels, or otherwise, particularly if sent to England, accompanying my own remarks as to the particular habits of the plant &c.

I further most humbly beg, (if your Excellency be graciously pleased to notice the above) I may be informed in due course, if it meets your approbation, and if my efforts will have protection against an indifferent regard to correctness, where the duty rests, for the performance of your Excellency's command in that particular.

I have the Honor to Remain, Sir, Your Excellency's Humble and obdt. Servt.

J. LEAR,
for J. KNIGHT, Esqr. }

Peradenia, April 23d, 1838.

The Rt. Hon'ble J. A. STEWART MACKENZIE, &c., &c., &c., Queen's House.

Peradenia, May 11th, 1838.

Sir,—I most humbly beg to return my grateful acknowledgments for your Excellency's kind attention to my request of April 23rd which I have duly received per letter with its enclosure. It has filled me with new energy for the performance of my hazardous duties and will strengthen every effort of mine that may have a tendency to merit a continuance of your Excellency's encouragement and good opinion.

I have the Honor to Remain, Sir, Your Excellency's most obdt. Servant,

J. LEAR,

The Rt. Hon'ble J. A. STEWART MACKENZIE &c., &c., &c., Colombo.

Sir,—I have felt it my pleasing Duty in the absence of Mr. Watson to forward for Your Excellency's Inspection the accompanying Forty Drawings, twenty of which have already been before you and lately sent me by Col. Walker. The remainder have been executed since my return from Putlam (and in great part collected on that route) by the Draftsman of the Establishment at Peradenia.

They represent the true character of the orchideæ to be found on that line of country, but are wanting in the essential points of a good Drawing *Botanical Desestion*, (sic.) a fault I hope will be hereafter remedied, I hope to be in Colombo

in a few days, and also to have the honor of representing to your Excellency the necessity of a different arrangement for the treatment &c. of my future collections and contributions to the Botanic Garden.

I have the Honor to Remain Sir, Your most obedient and Humble Servant,

J. G. LEAR.

Peradenia, July 18th, 1838.

The Hon'ble G. TURNOUR &c., &c., &c., Kandy.
Peradenia, July 2 th, 1838.

Dear Sir.—The dreadful and melancholy intelligence received here of Mr. Watson's death and the inconvenience the Establishment at Peradenia must suffer on the account has induced me to take this opportunity of begging permittance to assure you how much my services are at your and Government command during a short stay I find it necessary to make here.

I Remain, Dear Sir, Your obdt. Servant,
J. LEAR.

My dear Anstruther.—The enclosed from Mr. Lear was put into my hands this evening, and I subsequently met him and asked him what leave he meant to stay in this neighbourhood. He replied that he was at perfect liberty to remain, if required by the Government for any service, pending a reference to his Employer.

I informed him that I had no authority to accept the assistance offered, but that I would send his note accompanied by this explanation for the Governor's information.

I fear Mr. Watson's widow is left totally destitute.
Yours ever truly,

GEORGE TURNOUR.

July 20, 7 P. M.

To His Excellency the Governor, &c., &c., &c.

Sir,—I have the Honor to acknowledge the receipt of your Excellency's letter of the 20th instant, and am extremely sorry the melancholy and sudden intelligence of Mr. Watson's death has forced me to the necessity of remaining in this neighbourhood a little longer than I had expected when last I address'd Your Excellency and my fears at disappointing Your Excellency in consequence are so great that I have presumed to write again and offer the above to plead my apology.

I have moreover presumed to persuade myself that I should be considered wanting in gratitude to the distinguished kindness your Excellency has shown me, were I to neglect giving an eye to the Botanic Garden under existing circumstances, in the advancement of which I feel so deeply interested, exposed to as it is to the mercy of individuals whose knowledge and care is too confined to see or know that justice is done to it.

I moreover anxiously pray your Excellency will condescend to believe that however great may be the energy required to bring about the above Establishment to deserve the name it bears, my Services (as far as they will extend) are at your Excellency's command, until satisfactory arrangements be made for that purpose. Nor at any time shall the most strenuous exertion be spared on my part in the performance of any office I may be entrusted with, that is calculated to exalt the object of your Excellency's wishes.

In making the above offer to your Excellency it is under the sure conviction that Mr. Knight, my present employer, would blame opposite conduct in his servant on the present occasion.

I have the Honor to Remain Sir, Your Excellency's Most Obedient and Humble Servant,

J. LEAR.

Peradenia, July 23rd, 1838.

The Rt. Hon'ble the GOVERNOR, &c., Queen's House.

Sir,—I have the Honor to acknowledge the receipt of your Excellency's letter of the 25th current, agreeable to which I proceeded to establish some temporary arrangements for conducting the labour &c. of the Botanic Garden. Mr. Turnour being absent I waited upon Mr. Atchison on 27th for the benefit of his advice and assistance, but that gentleman referred me to Mr. Rugh, the assistant Government Agent, as the most proper person to take the part required by Your Excellency on that occasion, who also expressed himself bound to observe some delicacy in interfering in the matter from Your Excellency's instruction not having applied more directly to him. The latter gentleman, however, rode out to Peradenia and took a very active part in the interest of the Establishment. Government property has been collected with particular care and an Inventory taken of the whole (comp'ed today) except the plants which lie in such confused order that a day or two more will be required. Mr. Rugh and myself have examined some late writings of the Establishment referring to payments, abstracts, &c. (that were under the charge of the head clerk) of such a suspicious character that we could arrive at no other conclusion than to recommend an Investigation into his conduct (as far as is possible) referring to the business of his office. Mr. Solomonz, the clerk, has been absent since the 14th current and left in the absence of Mr. Watson when there was no one to conduct the business of the Establishment and has not since returned. Indeed his general conduct (omitting the above) is such as to merit for him a suspension until the matter is properly looked into.

A little reduction can be made in the labour of the Establishment without loss to the present condition of the garden which should take place when the payments are made for this month. But I must likewise humbly beg to state that it will not be advisable even for a short time to trust the Gardens or Superintendence of remaining labour to anyone or more of the people at present connected with it. The Draftsman would be materially improved under the superior tuition of Doctor Wight, and he is willing to repair thither at Your Excellency's pleasure, but if I may be allowed the suggestion I think it would be better that he be kept at home in good practice, if a few of his errors are pointed out to him. Scientifically he has taste to alter them and would soon acquire a proficiency. Amongst other business in which I have been much left to myself, I have noted what the Establishment requires to make it more efficient, and I shall submit it to your Excellency's consideration on my arrival in Colombo where I hope to be on Thursday 2nd per mail if Mr. Turnour whom I understand is expected in Kandy tonight gives me no directions to prevent it. I intend also to wait upon that gentleman tomorrow to know his pleasure. In every other particular Your Excellency's commands shall have my early and best attention.—I have the Honor to be, Sir, Your Excellency's most humble and obedient servant,

J. LEAR.

Peradenia, July 30th, 1838.

(Copy of Letter from COL. WALKER to MR. LEAR.)

Colombo, August 14, 1838.

Dear Sir,—His Excellency the Governor authorizes me to request of you to examine the whole of the dried plants at Peradenia with the view of sending such as are in a good state to Dr. Wight at Madras in order to be arranged and named.

Most probably a great number will have been injured if not destroyed by insects. It will therefore be advisable to make your report upon them to the Governor, when you will receive further instructions as to their future disposal.

The Draftsman having informed me of a large collection of his drawings of flowers (not Orchidea) it would in my opinion be well in you to look them over and report upon their state for H. E.'s information.

I am, your obdt.,
(Signed) E. J. WALKER.

The Rt. Hon'ble the Governor &c., &c., &c.,
Queen's House,

Sir,—I have the honor to forward to the Queen's House for Your Excellency one basket of fruits and vegetables, such as the Botanic Garden is now freely producing. In doing which I hope I am not pursuing a course uncalled for or opposite to the wishes of Your Excellency. There are now abundance of Alligator pears and vegetables of the same description as those contained in this day's basket, there will be likewise Rambutans shortly ripe. May I therefore be permitted to know Your Excellency's pleasure as to their distribution and regularity with which Queen's House should be supplied when any fit productions are matured and in season. I have taken the liberty to enclose a letter to Col. Walker in reply to his directions (authorized by Your Excellency) for the examination and report of Drawing and Dried Specimens of plants belonging to this Establishment, which direction shall have my best attention the earliest opportunity. The pot of the beautiful plant *orbanchæa* enclosed in the basket, I trust will have the benefit of Mrs. Col. Walker's pencil. It is found plentiful upon Hantany Hill near Kandy discovered by me a few weeks back but not seen before in full flower, which latter circumstance induced me to forward by this good opportunity a specimen for Mrs. Col. Walker's examination.

I have the honor to remain, Sir, Your Excellency's most obedient servant,

J. LEAR.

Peradenia, August 17th, 1838.

COL. WALKER, &c., &c., &c., Colombo,

Dear Sir,—I have the Honor to acknowledge the receipt of your letter of the 14th instant, and beg to inform you that I will take the earliest opportunity to examine the dried specimens of plants and report upon them agreeable to your request. I am at present engaged (by His Excellency the Governor's direction) in making out a catalogue of the living plants in the R. B. Garden, which I find no easy task amidst the confusion in which they are distributed, and as the jungle requires to be cut down to enable me to get at some of the specimens (even those in part that have been introduced here at considerable expense), I have also a report to finish on the present condition of the R. B. Garden for His Excellency's satisfaction which will accompany the Catalogue. The joint employ will occupy me some short time longer owing in a great measure to the unsettled state of the Establishment. May I therefore be permitted to enquire if I may postpone the examination of the specimens and drawings until the above work is complete.

I have the honor to be, Dear Sir, your most obedient servant,

J. LEAR.

Peradenia, August 17th, 1838.

I have succeeded in procuring a fine specimen of the order *Arobanchæa* I once showed you in Kandy, and have taken the liberty to enclose a pot of it

in a basket this day sent to the Governor, which I trust will arrive safe and have the benefit of your and Mrs. Col. Walker's inspection.

K. H. STEWART MACKENZIE, A. D. C., &c., &c., &c.

Sir,—I beg to acknowledge the receipt of your letter of the 20th instant, and in reference to that part of it which enquires my "present terms of agreement, pecuniary, and others, with Mr. Knight." I beg to inform you, the particulars for His Excellency the Governor's information.

My anxiety to arrive at a more perfect knowledge of Botany, (in addition to my experience in General Gardening) led me to an early acquaintance with Mr. Knight, and time, to an unshaken confidence on both sides. Mr. Knight (knowing my wishes) chose the opportunity of sending me abroad to tread the paths of nature, perfect myself in the work I had commenced, and at the same time be serviceable to him, and Science, in as much as Botany is concerned. The particular object was my improvement and honourable reputation; however, so much so, that *pecuniary terms*, and advantages, were of no consideration, nor were any entered into, or even proposed, (by Mr. K. or myself) in the most distant manner, except that I should always enjoy the kind patronage of that celebrated gentleman. Mr. Knight defrays all the expenses attendant on my researches and travels, and allowed me 3 years to labour, in search of Botanical knowledge, under his protection, sending exclusively to him the fruits of my labour. The term 3 years was not specified that I should remain under Mr. Knight that period, but because it was thought sufficient for the purposes, as above alluded to. There was no Bond entered into betwixt Mr. Knight and myself, nor was one required or necessary, but Mr. Knight must be informed when any alteration takes place in our present arrangements, through his Agents or otherwise.

I can "with Messrs. Wilson and Archer's consent take any employment in Ceylon," but I should hesitate to do so very much unless I be allowed an opportunity to serve Mr. Knight with good attention. With respect to the remuneration I should expect per month, I beg to state that if it was, I should have to follow an employ, embracing opportunities for my further improvement in Botanical knowledge, I should rather decline, fixing any sum myself from the combined reasons above specified, added to that of my wanting tropical experience.

For more particulars on this subject, I beg to refer you to a letter from me of August 20th to P. E. Wodehouse, Esqr., Assistant Col. Secretary, and a memorandum of an interview I had with Mr. Turnour (under the direction of Mr. Anstruther) in Kandy on the 11th of August, when a sum was specified by that gentleman for my temporary superintendence of the Royal Botanic Garden, Peradenia, to be forwarded for His Excellency the Governor's consideration, the terms were all perfectly agreeable to me.

I mentioned to His Excellency when I was last in Colombo, that one year's servitude under Mr. Knight's protection was about to expire, and that it was my determination to establish myself in Ceylon, but I did not intend to be understood that I should leave Mr. Knight until the 3 years should be expired, except an opportunity offered in Government Service, the which I shall feel happy if His Excellency be informed.

I beg to send enclosed a note from Mr. Turnour referring to a memorandum of our interview (intended to be sent to His Excellency the Governor) for the Governor's satisfaction, in answer to your enquiry if I had communicated with that gentleman or Mr.

Anstruther, on the subject of my having temporary duties to perform for Government.

I have the Honor to be, Sir, your most obedient Servant,

J. G. LEAR.

Peradenia, August 22nd, 1838.

Dear Sir,—I handed the Memo of our interview on the same day to Mr. Anstruther, who I have no doubt has since sent it to His Excellency from Neura Eliya. In the possible event however of his having lost sight of it, I will send your note to that gentleman, and you can send this over to Colombo, to shew that no time has been lost in acting on the Governor's wishes.

I remain, Dear Sir, Yours obediently,

GEORGE TURNOUR.

J. G. LEAR, Esq.

The Hon'ble P. E. WODEHOUSE, Esq., Assistant Colonial Secretary.

Royal Botanic Garden, Peradenia, Sept. 15, 1838.

Sir,—I have the Honor to enclose a plan of the Royal Botanic Gardens, Peradenia, A Catalogue of plants and a Report, which I beg may be forwarded for the Rt. Hon'ble the Governor's information.

I have the Honor to be, Sir, your most obedient servant,

J. G. LEAR.

A REPORT ON THE PRESENT STATE OF THE ROYAL BOTANIC GARDEN, CEYLON, WITH A PLAN, DESCRIPTIVE OF THE MANNER IN WHICH IT IS OCCUPIED, A CATALOGUE OF THE PLANTS IT CONTAINS AND OTHER REMARKS.

The land allotted to the purpose of the Botanic Garden is in quantity one hundred and twenty-one acres, situated at Peradenia, three miles from Kandy, the interior Capital of the Island, bounded on the North by the main road leading from Kandy to Colombo; on the East, West, and South, by the fine and in part navigable river *Mahavilla Ganga*; the situation was appointed by the late indefatigable Botanist, Alexander Moon, Esquire: it is well chosen, and the most eligible the Island offers, to meet the various, important and complicated uses of a Botanic Garden. The climate is intermediate and undergoes but a trifling variation; Fahrenheit's thermometer standing on an average at about $77\frac{1}{2}^{\circ}$, the soil is a fine rich, friable loam, unequally mixed with portions of decomposed vegetable matter, sand and clay, which by artificial mixture with other soils of the neighbourhood, may be suited to the growth and cultivation of all the vegetable productions of India, and those likewise from other countries, that have a probable chance of success in any other part of the Island.

It was the original intention to divide the Garden into different departments, and to have a systematical arrangement, usual in the general formation of such Establishments; but, from the unfortunate circumstance of the death of its founder, A. Moon, the plans were disturbed, and became subject to much inattention; the Establishment has since been, but for very limited periods, under the management of experienced Superintendents, and has in consequence been thwarted from its original design, allowed to proceed agreeably to the often ill-adapted taste of its managers, frequently to that of the native people, but generally as nature herself directed, and now exposes a face of such confusion, non-arrangement, and neglect, that would place a stranger in a situation to ask for what was it intended.

There are sixty-five acres which the plan describes planted with coffee, interspersed with Coconut, Jack,

Cinnamon and various forest trees, which were let in 1836 on lease of ten years to Henry Wright, Esquire, and forms by far the greater portion of the garden at present under cultivation; the Coffee trees are in various stages of growth, from one foot high to eight and in general are in a very unhealthy state, comparatively unproductive and irrecoverable; they will unquestionably produce sufficient Coffee, amply to compensate the present occupier, but at the expiration of his lease, it is more than probable they will have become nearly exhausted.

There are about one and a half acre cultivated as a kitchen garden, which partakes of the general feature, injudicious management, it is capable of wide extension, and of being brought under a high state of culture with little trouble; produces fine vegetables, but is dependent upon no regulation for a supply of seeds; and is frequently in a state of pitiable nakedness.

It is formed in a low part of the Botanic Garden, near the river, on the eastward side, and is well calculated to ensure success, in the various objects of its application; the only objection that can be formed to the situation is, that it is liable to the inundation of the river, when the fall of rain has been unusually great, which was the case in the year 1837, and the garden suffered much in consequence, but it has only once occurred during the memory of the oldest inhabitants that the river has risen so high as to inundate any portion of the premises, and the Kings of Kandy had previously occupied this same situation for their Royal Gardens.

There are also about four acres under cultivation as an Orchard, and furnished with Fruit Trees of different kinds, but mostly with those that are common through the Island, and with few exceptions, possess but very inferior qualities; it has been very much and long neglected, the truth of which it exhibits to every common observer, and also the great want of a superior assortment of Fruits, the which may be obtained at a cheap rate by exchange with other countries.

The performance of necessary work would soon recover this department, and with a supply of good plants, well cultivated, everything is favourable to a prolific and satisfactory result.

About one and a half acre are allotted to a Spice Garden, two-thirds of which is planted with Cardamoms, the remainder with Nutmegs, Cloves, Chocolate Nut, Cinnamon, and various ornamental flowering plants; this department ranks with the preceding with respect to condition, but has more commendable features, the Spices are of excellent quality, the trees are also vigorous and healthy, producing fine fruit, in reasonable quantities; which, with every other appearance convincingly indicates that the climate, soil, and other circumstances on which the perfection of these valuable articles depend, are particularly favourable.

About four acres are occupied as a Nursery and pineground connected, the state of which evinces a very powerful proof, that the worst description of negligence, or want of skill, has been companion to the system of its management for some considerable period.

The Nursery is very indifferently stocked, consisting chiefly of plants and cuttings most common on the Island, and those which propagate with ease and facility. After the cuttings were put in the beds, they have been allowed to remain unmolested, and some seem to have been there the last seven or eight years, and are grown into such masses, and so large, that they cannot now be removed without destruction.

The work has been left exclusively to natives, and but few attempts seem to have been made to increase any plants, when the process was attended

with difficulty, or when success depended upon judgment and experience.

The consequence is, that the Garden is overspread with a superfluity of common Island trash, much to the discredit of the Establishment, and the frequent injury of some foreign, but beautiful specimens that have remained unnoticed; which (if they had been properly increased and circulated) might have proved of great utility to the public, and particularly to the native population of this Island, by offering objects to stimulate their industry in the easy requirement of at once useful, profitable and splendid plants, the production of other countries.

The Pines in like manner are planted after the native system, and have been allowed to remain (as nature would) to propagate themselves, art only assisted when fruit was ripe, plants wanted watering, or when it was desired more land should be planted with them; this fine fruit may be brought to a high state of perfection, with very little trouble, and may be multiplied at pleasure into immense quantities.

The remaining part of the Garden under cultivation, is about ten acres, divided into flower plots as is shewn in the plan, planted without system, attention to nature, or economy and the management shares in the common indifference, pruning has been but seldom adverted to, and when that has been the case, it was evidently by an unskilful hand, for the plants and trees are generally of the most irregular and offensive shapes. The Borders expose a very irregular surface, and from not having been loosened the last four years, are become so hard, that it is next to impossible for plants to arrive at a state of natural luxuriance in them; the only attention they seem to have received was keeping them partially free from weeds. The Walks and Drives occupy considerable space, and are much out of repair, the water has washed away the gravel to a considerable extent (which has not been replaced) and formed channels also by their sides so extensive, as to become both dangerous and inconvenient; this is not invariably the case, but the worse predominates, and indeed it must here be acknowledged, that the labour of the Establishment is insufficient to keep them in proper order on so extensive a scale, without subjecting other parts to injury or neglect.

That portion of the Royal Botanic Garden not under cultivation, is about forty-five acres, all in dense low jungle; it occupies some prominent and fine parts of the Garden, a great deal of which has been under cultivation, and some fine specimens of plants are now remaining on it, but they are totally neglected.

The drives surrounding these parts are likewise overgrown with jungle, and are become quite inaccessible without much labour; the drains that carry off the water occasioned by the heavy rains are also much out of repairs, they were constructed too temporary and with bad materials, and to this may be attributed the chief cause of the walks and drives being now in bad condition; they may be put in good repair at a small expense, the necessities for such work being convenient and to be had at reasonable cost.

The water, so essential and valuable an article to the premises, is of superior description, the demands for which is supplied by a stream from the neighbouring hills, and is capable of being conducted to any part of the Garden with ease and expedition; indeed it would be difficult to find a second situation, where water on such an extensive scale is required, that can be so well accommodated.

At present there are but two temporary reservoirs, and those very small to receive the water for the use of the Establishment, one in the Kitchen

Garden, thus rendering a considerable portion of labour necessary to carry water to distant parts of the premises, which can, and may have long been avoided at a comparatively trifling outlay.

The store contains an incomplete but good assortment of Tools, but they are also in part very much worn, and many are become quite unserviceable; good tools are a great saving to manual labour, and materially assist the quality and expedition of work, which points out the utility of providing a regular and proper supply, whilst the present general condition of those in hand does the necessity; there are however many that will not immediately require replacing, and the stock of some kinds is quite sufficient to last for several years, so that the quantity necessary at present is not very considerable.

The Establishment since 1830 has consisted of a Superintendent, Clerk, Draughtsman, Blacksmith, Carpenter, Seed Collector, Kangany (or Head Overseer) Gardener, Foreman, two Lascareens, thirty Coolies, and eight Boys, with six bullocks for drawing manure, &c., &c.

The Expenditure for which has been on an average, upwards of nine hundred pounds per annum, which sum, after the grounds are put in proper condition, is more (by one hundred and fifty pounds) than sufficient to keep it up in order, of first-rate excellence, that is, seven hundred and fifty pounds per annum, would defray the whole of the fixed and unfixed contingencies, leaving the profits of the Establishment to pay the extra labour required for the first two years, after which upon the best, and most mature calculation, there is every reasonable probability that the profits of the Garden would return two hundred pounds per annum, thus reducing the actual cost of supporting the Establishment to five hundred and fifty pounds per annum, and even that some in the course of a few years may be much reduced.

(To be continued.)

THE COMMERCIAL VALUE OF GREAT BRITAIN.

Under the auspices of the Institute of Bankers, on Wednesday evening, Mr. J. Scott Keltie, librarian of the Royal Geographical Society, delivered, at the London Institute, Finsbury-circus, the third of a course of four lectures on "Commercial Geography." Mr. Billingham, of the London and Westminster Bank, again presided.

The lecturer stated that, including every scrap of land over which we had any claim—the mother country, India and her feudatory States, the colonies, protectorates, and spheres of influence—the area of the Empire was probably not less than ten million square miles—very nearly one-fifth of the whole land area of the globe. It was nearly three times the size of Europe; one and a half million square miles larger than the whole of the Russian Empire in Europe and Asia; ten times the size of the German Empire at home and abroad; eight million square miles more than the whole of the French dominions, even including Madagascar; and just about a million less than the area of Africa. On this immense area there lived and worked something like 350,000,000 people, embracing almost every type of humanity under the sun. Thus of the total population of the globe, about one-fourth or one-fifth were our fellow-citizens. An agricultural country could never support a very dense population, and in so small a country as ours could never have much surplus capital for great enterprises or surplus inhabitants for purposes of colonization. Our coal and our

iron had, to a great extent, been the making of us and had enabled us to avail ourselves of our geographical advantages. The total value of our trade had grown enormously within the past 39 years. In 1860 imports and exports together amounted to £365,000,000; in 1889 their value was £740,000,000. Our imports 30 years ago, were valued at £210,000,000, now they were £427,000,000; our exports 30 years ago were £164,000,000 now they were £313,000,000. About 40 per cent of our imports consisted of food products, and about 35 per cent of raw materials of various kinds, to be used, directly or indirectly, for manufacturing purposes, partly our own consumption, but largely also for being exported in a manufactured state. Over 60 per cent of the raw material consisted mainly of raw cotton and raw wool which were manufactured into textile materials to be exported to all parts of the world. Nearly one half our exports of home produce consisted of fabrics of raw materials in various stages of manufacture. Cotton manufactures and yarn alone amounted to somewhat less than one-third of the total exports, while metals in various stages of manufacture (including machinery) amounted to somewhat less than one-fourth. Our great raw export, coal, formed only about one-seventeenth part of our exports of home produce. The relative importance of the mother country so far as size and population were concerned, compared with the rest of the Empire might be seen from the fact that of the ten million square miles only 121,000 belonged to the United Kingdom. The population of the mother country was today close on 38,000,000 or just about one-eighth part of the whole of her Majesty's subjects. The whole trade of the Empire might be valued, imports and exports, at about £1,200,000,000 of which about 68 per cent was the share of the mother country, leaving just 32 per cent, to the vast remainder of the Empire. Mr. Keltie then dwelt in detail on the commercial, strategical, and geographical features of the Empire beyond the seas. On the whole, he said, we were fortunate in our colonial Empire—much more fortunate than France or Germany, Portugal or Spain, who, except France, had very little beyond the tropics. The proportions of our colonial Empire, too, were well adapted to our wants. He had stated that the total trade of the Empire might be estimated at about £1,200,000,000 annually. That was just one-half of the trade of all foreign countries put together. Of the £1,200,000,000 we must credit £460,000,000 to that portion of the Empire beyond our shores. Of these £460,000,000, about £170,000,000, belonged to the seven million odd square miles of what we called colonies of settlement, with their population of 10,000,000, mostly whites. The remaining £290,000,000 must be credited to the tropical and sub-tropical possessions, which covered only about 2,700,000 square miles, but with a population of some 300,000,000, among whom was only a sprinkling of whites. Of the £290,000,000 of trade allotted to tropical possessions, about £180,000,000 belonged to our great Indian Empire. About five-sixths of India's imports of merchandise came from us, while of India's own produce about three-eighths came to the United Kingdom. Whatever habitable parts of the earth were available for European settlement had fallen to the lot of English speaking peoples, and among them we must reckon the United States, which we could not treat as a foreign country, and which did an annual trade of £300,000,000, of which £90,000,000 was with the old mother country who in this matter stood far ahead of all others. In commerce, as in some other things, blood counted for something. Whether our colonies remained attached to us, or whether the

larger ones—which now managed their own affairs—might, like the United States, set up for themselves, the future alone could tell. Whatever form it might take, however, he thought that, in the interest of commerce as much as for sentimental reasons, we ought to stick together. The spread of our race on the face of the earth, the enterprise of our explorers and adventurers, had helped to give us predominance in the commercial, as it had done in the political, world. In one form or another the English language was the medium of communication for something like 400,000,000 people—nearly one-third of the population of the earth; and some who tried to forecast the future thought it might yet become the universal language. When we remembered that more than one-fourth of the whole trade of the United Kingdom was with the rest of the Empire it was surely our interest to do all we consistently could to promote that commerce and to encourage the development of our colonies and the judicious extension of the British sphere. As yet our colonies could not do without us. One means among others of enabling us to keep our place with so many powerful rivals in the field was to acquire a full knowledge of the geographical conditions which bore on the interests of commerce.—London *Times*.

PERAK TEA.

Some of the English newspapers are writing enthusiastically about Perak tea. A small lot, which was recently put upon the London market, is pronounced to be of excellent quality, and the good people at home at once assume that a new and important source of supply is open to them. We fear, however, that for a good many years at least, they are doomed to disappointment. That Perak tea is of excellent quality and delicious flavour there can be no doubt. We draw attention to this long ago, and pointed out how suitable the soil and climate of Perak, and other parts of the Malay Peninsula, are for tea cultivation. But soil and climate are not the only essentials for its successful cultivation. Its agricultural success has been proved: what has not been proved is its commercial success; and that after all, is the test to which it must be put before it can be pronounced an unqualified success. And it is only too evident that, with so much else in its favor, the chances of commercial success for the present look remote. Tea requires cheap labour, and labour in the Straits Settlements and neighbouring countries is excessively dear—that is, it is dear compared with the labour of other tea-producing countries. The pay of Tamil labour here is much higher than in Ceylon; it is much higher than the pay of coolies in Assam, Cachar, and the other tea-growing districts of India, and much higher than in Java. Besides in those countries a great deal of the tea leaf picking is done by women and children; whereas in the Malay Peninsula Tamil women and children are scarce, and with the restrictions and difficulties put in the way of emigration from India, there does not appear much likelihood of their soon becoming more plentiful. There are of course the natives of the country—the Malays. If their women and children could be got in sufficient numbers, or indeed could be got to work at all, the difficulty would be settled. There would be some inducement for planters to open tea estates in Perak, and Perak tea would, in all probability, become a factor in the tea market. At present, we fear, there is no such inducement. To plant tea in the Perak on a commercial scale without a cheaper and more reliable source of labour, would be foolish, and could only end in heavy loss, unless, of course, the trees were unusually fruitful or the tea of such quality as to command a fancy price. We wish it were otherwise, for we should like to see the agricultural resources of the Peninsula developed. Cheap labour, however, is essential to attain this end, and cheap labour there seems no probability of getting for a long time to come.—*Pinang Gazette*.

CEYLON TEA IN THE LONDON MARKET DURING 1889.

On succeeding pages we now reproduce the whole of the valuable Report of Messrs. Wilson, Smithett & Co. (received by last mail) together with their long and interesting lists of the sales of Ceylon Estates' teas with total quantities and average prices realized during 1889. We have already analyzed the Report and noticed the salient points. But we may call attention to the interesting statistical returns appended to the Report.

We also make considerable extracts—all bearing on Ceylon teas—from the Annual Report of Messrs. Geo. White & Co., another well-known London House who deal with Indian, Ceylon and Java teas in the one Report. The whole of this matter being embodied in the *Tropical Agriculturist* will make the matter easy of access for reference to our planting readers at any time.

GEMING MINING PROSPECTS IN BURMA: SIR LEPEL GRIFFIN'S VISIT.

(Continued.)

HEALTH AT THE MINES—PREVALENCE OF LIMESTONE—THE MATRIX, A MYTH?—WHERE THE RUBIES ARE FOUND—LITTLE WORK DONE: MACHINERY NOT TRANSPORTED—FOUR DIFFERENT MODES OF MINING.

It has been apparently the old story over again: disregard of men with local knowledge and local experience, who know how to live in the country under all conditions, in fact the fittest who have survived when the others have perished, and the engagement of men whose brief knowledge of life has been gained in Europe, in their own native country, and who as a natural consequence fall victims to the first maladies to which they are exposed. It may perhaps be said that the civil and military officers in the district have suffered as much as or more than those of whom we are writing; but inquiry will demonstrate that the over-exertions and exposure consequent on the prosecution of their duties must necessarily prove almost deadly. It would be the same in their own native country. They tell of fording icy cold rivers a dozen times a day, wet up to the middle and their clothes drying on them; obliged to be content with such food as they could carry with them or pick up on the way, and this for stretches of 36 and 48 hours on end; and hardly a decent shelter for weeks together—hunting dacoits. Such a life is sufficient in itself to destroy the finest contribution apart from any question of climate or malaria. Another matter in this connection may be alluded to without committing ourselves to an opinion. In Ceylon, fever is said to be more prevalent where the water used by the inhabitants runs over limestone, which it seems is the case to a very large extent in the ruby mines district. In fact limestone of different kinds seems to be present in great quantity all over Burma; and if there is any truth in the Ceylon theory of fever resulting from the use of such water—it may possibly help to elucidate the mystery which attaches to the prevalence of fever in situations which might be supposed to be favourable to the health of Europeans, for instance Mogok and Bernard-myo at an elevation of 4,000 to 6,000 feet above sea-level.

It is in reference to the existence of this limestone at Mogok and in the ruby mine district generally that Mr. Streeter announced with a considerable amount of jubilation that the matrix of the precious rubies had been discovered, and congratulated the shareholders of the Company on having secured the monopoly

of working it, and for this matrix of crystallized limestone he insisted search should be made in Ceylon, before any operations were commenced in the formation of a company. It transpired however very shortly after this expression of opinion on the part of Mr. Streeter, that the first thing that would engage the attention of the Company's engineers was the collection of gems from the alluvial deposits in the flats and valleys of the concession, going so far as even the bed of the river from which the water was to be diverted. On the return of the Chairman and party from the mines, Sir Lepel Griffin was asked about this matrix and what was proposed to be done with it. His reply was as follows:—"I fancy the great bulk of the rock in that part of the country is limestone; there is gneiss and a great deal of clay. There is also some very fine true alabaster. We are driving one drift through the side of a hill into an old shaft which some of our English miners are now sinking. It goes through a bed of pure alabaster. It is not very hard to work, though we had to use dynamite to blast it." Being reminded that Mr. Streeter had been assured the best gems would be found in crystallized limestone, he said:—"Yes, there is a sort of granulated limestone which is a good find I believe, but we have not touched it yet. We have some reports on the subject from the Ruby Mines, but I am not at all satisfied that we have sufficient scientific knowledge about the strata. I have asked Mr. Noetling of the Geological Survey to visit Mogok. He will be there in a month's time, and I hope he will be able to give us a great deal of assistance. He is a very clever man and will be able to point out where the best chances are. As for the gneiss, as far as I saw, it was not *in situ*: it is scattered about and disintegrated, mixed with clay and loam. Most of the rubies are found in the stuff called *byon*—which is a sort of clay mixed with gravel and sand, disintegrated gneiss and limestone, caked together. It comes in strata five to ten feet thick, under the alluvial clay. It has been washed into great fissures in the rocks, which is a different form of mining but still it comes to the same thing. The *byon* varies immensely in different places. It is not by any means all of one sort. In some places, especially in the lower beds of the river, it is so mixed with large gravel and pieces of rock, that I think it will be very difficult to pass it through washers at all. There are garnets as well as rubies in the same kind of limestone. With the aid of pumps we hope to come upon a new stratum which has never been touched at all, especially the alluvium of the plain and the bed of the river." This is all the information on this part of the subject that was elicited from Sir Lepel Griffin, and it was well he deduced from what he has said that very little is known of the matrix at Mogok by any of the officials connected with the mines. The executive engineer of the works did not pretend to have any knowledge of it further than having to devise some means at some future day of extracting the gems from it. He called it "Calcareous" limestone, whilst Sir Lepel Griffin spoke of it as "granulated" limestone. In an article on this subject written from information gathered in conversation with the executive engineer of the Company we are told:—"There are at least two principal district locations in which the precious gems are to be found, and their most facile and economical abstraction from these of course engages the attention of the engineers as well as the manager of the mines. Rubies are found embedded in a stiff clay which is no doubt an alluvial deposit. This clay varies a good deal both in colour and tenacity as well as in com-

position. In some localities it is almost petrified, in others it is comparatively soft and easy to work. Crushing machinery forms part of the plant provided by the engineers of the Company. The other position may be described as in the *matrix* or to use a technical term *in situ*; and when we allude to this, we must confess that the position is not so simple as in the alluvial deposits. In fact the attention of the Company seems likely to be almost wholly taken up by the alluvial deposit, leaving the more difficult abstraction of the gems, from the matrix to a future opportunity. These conditions we believe are almost identical with those under which gem collecting is conducted in Ceylon. Deposits of gemiferous clay are found all over the principal mining districts, and the stones are carefully washed and separated from the surrounding soil, whilst the gems in the matrix are left to be discovered and collected in some indefinite period of the future history of the island. As is no doubt well-known in Burma, the Burma Ruby Mining Company have an almost exclusive right to the use to explosives in mining operations, but for anything that is apparent at present, they have no immediate intention of availing themselves of the privilege such a monopoly necessarily involves. They are apparently perfectly content to work the alluvial deposits at present, being confident that their enterprise will be amply rewarded before any necessity arises for their searching for gems in the adamantine matrix in which nature has placed them."

So far then as regards the *matrix* very little reliable information has been made public, and it may fairly be deduced from what is said about it that very little is actually known of it. It is only now that the Company has been in existence a full twelvemonth, that a scientific expert has been requested to visit the district and point out the most likely spots for successful search. There is a report current throughout the country and corroborated by the evidence of one of the Europeans stationed in the Mogok district, that there is not a single European in the employ of the Company who can tell a ruby from a cockleshell, and that valuation and purchase of stones is left in the hands of a Chinaman named Ah Sin. It is hardly necessary to add that this Celestial is credited with making a large fortune for himself, but doing a bad trade for the Company. How it is possible that this can be done will be seen when a description is given of the mode in which so far the Company have acquired the rubies they have exported.

In the first place the Company has done nothing or next to nothing in the way of mining on their own account. The machinery sent up by Mr. Streeter early in the last year is nearly all of it lying at Thabeittiya on the bank of the river. This machinery was taken over from Mr. Streeter by the Company, but is now said by the executive engineer not to be suitable for the work, and also unavailable having been sent out in pieces, for putting together of which neither skilled men nor workshops existed at the mines. The road was not completed until a few months ago—and other more suitable machines have been obtained and will shortly be erected. At the same time it is asserted by some who ought to know, that for some time past the mechanical engineers and fitters at Mogok in the Company's employ number twelve persons, and all they have as yet done is to erect and fit up a steam pump! Taking such a statement for what it is worth, we know that there are twenty Europeans at Mogok and some 300 workmen and 75 to 80 Gorkha police: these figures have been given by the executive engineer. Before repeating what was said by Sir Lepel Griffin

on the subject, it will perhaps be as well to explain the mode in which the Ruby Mines Company have become possessed of gems. Certain persons, natives of the district and claiming to have hereditary rights of mining, are granted licenses to dig for gems under certain conditions, the principal of which is, that all stones of value are to be brought to the Company's nominee, who makes an offer for purchase of the same. If this offer is not accepted, the stones have to be sent to Mandalay, and deposited in the Treasury. In due course they are exposed to public auction, when the Company's agent has again a right to bid. Rightly or wrongly the presence of this agent at the sales in Mandalay is stated to be a reason for the market value remaining low, when it is well-known that very considerable values of stones are continually being smuggled out of the country. This is explained as follows:—When no other agents are present at the sale, the Company's man has it of course all his own way and purchases at his own price. He at once constitutes the demand and ruler of rates. When other purchasers are present the Company's man can always find it in his power to outbid them,—though of course the purchases on that occasion may be at an actual loss. Finding they cannot trade at reasonable rates, the outsiders refrain from attending the sales, and the Company's Agent reverts to his previous position of monopolist.

There is no doubt plenty of room at the mines for profitable employment of hydraulic machinery for the raising of water and carrying it by pipes to the places where it is required for washing the ruby sand. A number of the hill mines (*Huawdwin*) can now only be worked in the rains. These are simple cuttings in the hill sides, water being led to them by artificial channels. It is said the best stones are found in the valleys. There are apparently four modes of mining in the ruby mines district at present. The *Huawdwin*, described above; *Loodawdwin*, a gallery run into a hill side; *Asoodwin*, a hole or well dug into the ground containing water; *Achowckdwin*, a hole or well dug in the flat ground containing no water. There is a good specimen of the gallery system at Bormadaw, which has been worked for a long time by the Burmese, but want of ventilation makes the working difficult now, and it is a laborious effort to get out the rock without blasting which caused many accidents and which was therefore put a stop to shortly after the annexation. Bormadaw is a hill about 4,750 feet in height. The passage to the ruby mining gallery is a narrow hole between large rock boulders, 100 feet deep; between these the ruby sand has fallen and filled up whatever spaces were left, the water finding its way further down the hill. The Burmese have carefully scraped out and collected all the ruby sand where the passage between the boulders has been large enough to admit a man. All up this mountain are mines of one or other of the descriptions above given, and if blasting was allowed and carried on scientifically, the finds would, no doubt, be more profitable than they have been lately. There are thousands of tons of this ruby bearing rock on the hill, but as at present worked the finds here are not very profitable." Here is a description of one of the other methods of mining mentioned above:—"The chief employment is mining, in which all the men and many of the women are engaged. The methods of mining are very primitive especially in what is known as the 'Asodwin,' which is used in the alluvial deposits of the valleys. A pit is sunk in the soft ground down to the ruby sand below. The sand varying in quantity from 4 or 5 cwts. up to two tons according to the size of the pit, is taken out and washed for whatever it

may yield and the pit is then abandoned. No attempts are made to follow the ruby sand below by tunnels or adits even when the earth above is firm and the ruby sand itself is free from water. The small quantity of ruby sand so obtained appears to be in most instances quite rich enough amply to repay the six or seven days labour necessary to obtain it, and the fact that so little outlay is required for each operation, recommends it no doubt to the majority of miners." From this it will be seen that so far, all the ruby collecting in Burma has been conducted precisely on the same lines as in Ceylon and is still so conducted on the concession at Mogok. One more statement coming direct from the mines and we shall close our remarks on this point. "Do you know how the rubies are got? Why, the licensee has a bit of a hole cut near a stream, five or six feet wide, and then you see a woman standing in the water, scraping up gravel in a basket and picking out the stones, whilst half a dozen constables sit round the hole smoking and talking, supposed to be watching that the woman does not steal any of the stones, that 's how its done."

BRITISH HONDURAS

is the subject of a contribution to the *Field* of 21st Dec. 1889 by J. B., who paints in glowing colours the advantages of this hitherto neglected colony to young men seeking "fresh woods and pastures new." In fact, barring the existence of some unhealthy localities on the coast, the place seems to be a veritable paradise. The writer terms it

A country of hills and valleys, of running brooks and rapid rivers, a land of primæval forest, almost uninhabited, of which less is known comparatively than of Central Africa, a land compared with which the boomed and vaunted Florida is but a wilderness. Here is a country in which land is still cheap, the best being only \$2 per acre. True, some of the low-lying parts of the coast may not be healthy; but there are many places, even on the coast, which are remarkably so. On fine open beaches, well exposed to the constant south-east trade winds, are famous sites for coconut plantations, whilst a little farther back almost all the tropical fruits may be grown in perfection, especially all of the Citrus family, oranges and limes, within a few yards of the sea, the latter laden with fruit at three years. Of all the colonies which I have visited, I know of none in which a new comer is so well received, where the officials, from the highest to the lowest, show so much attention, and where the governor himself takes a direct interest in the welfare of every new settler.

Again he says:—

A more beautifully watered country I have never seen in the tropics or out of them. There are no less than fifteen rivers between Old River and Sarstoon, besides numerous small streams; on these, but for the occasional view of a palm, one might fancy oneself on one of our Welsh or Devonshire rivers, such as the Dart, winding between wooded hills over a fine gravel bed, with boulders of quartz and granite forming rapids and cataracts, the land on either side the alluvial deposit of ages, of great richness, and suitable for the cultivation of almost all the tropical products of commercial value, and much of it well adapted for cattle and horses. Many valuable timbers are to be found, and large quantities of rubber and cacao, and doubtless many medicinal plants, and gum and balsam yielding trees, as in Brazil, hitherto unknown because unlooked for. Of the mineral wealth of the country also there can be little doubt, the formation of the main mountain range being identical with that of Guatemala and Spanish Honduras, where the precious metals are found in abundance. In many places large quartz reefs may be seen, well exposed, easy of access, and close to good water-power.

That planters have every prospect of success may be judged from the following:—

Formerly sugar was successfully cultivated on several estates; but since the depression in that trade, these have been allowed to fall out of cultivation, and up to now there has been nothing done in what usually comes under the term of planting—for the way in which bananas are grown cannot honestly be called cultivation. Apart from these are the old original industries of mahogany and logwood cutting, both most precarious, depending entirely on the seasons, there being no means of transport but by the rivers when in flood.

The great want of the colony, the writer says, is roads to open up the land. The ubiquitous Ceylon planter has already established himself in British Honduras, for we are told:—

Twenty-eight miles from Belize is the mouth of Mullins River, with its old and considerable Creole settlement. The river is noted for the good land on its banks, and it is here that the cultivation of bananas as an article of trade was first introduced. In addition to the small Creole plantations, there are several large estates owned by Englishmen, notably those of Mr. Walter Bennett, O. C. Price, and J. Q. Swayne. Mr. Bennett, who is a planter of several years' experience in Ceylon, says that the hill country to the westward is far richer, and as well suited for the cultivation of coffee and tea as that of Ceylon. The natives grow small quantities of very good coffee even on the river banks, and at a comparatively low elevation, but they are quite ignorant of its cultivation. Guatemala exports a large quantity of coffee, which commands a good price, and it is impossible to say where our colony ends and Guatemala begins, the vegetation and geological formation being similar. Theobroma cacao of excellent quality is found wild, and, if cultivated, would yield a handsome return, the demand over Central America alone being in excess of the supply. True, it takes some years to arrive at maturity; but still, anyone engaging in the fruit trade, which is enough to keep the pot boiling, should be always planting a tree, say, of coffee, cacao, or rubber, and in ten years' time he would find himself in a good position.

Good shooting is also to be had. The writer gives his own experience with regard to the healthiness of the colony, and concludes as follows:—

I only trust that I may be the means of inducing others who may be in search of a new place in which to settle, or pass a winter, to look up a country where they may remain under their own flag; and after an experience extending almost all over the world, I can assure them that there are many worse places than British Honduras.

No one who is not either a labourer or a mechanic must suppose that he can do there, or anywhere else, without a certain amount of capital; but I believe there is no place in which a man may start with so little, and yet derive a certain income at the end of at most eighteen months.

English and American moneys are at a high premium—say, at the lowest 30 per cent.; and it is probable that the Government may see their way to offer greater inducements to settlers by still farther lowering the price of land, or by introducing a Homestead and Pre-emption Act, and by assisting in the importation of labour, which is much required.

Although I am acquainted with its details, the subject of banana-growing has been so well treated in Mr. D. Morris's "The Colony of British Honduras: its Resources and Prospects," and in an excellent article by Mr. Walter Bennett in "The Handbook to British Honduras," which I have already mentioned, that it would savour of plagiarism were I to endeavour to give further advice or estimates. But this much I may say, that a steady man with not less than £500 ought to be able to make a very good start in British Honduras.

CEYLON UPCOUNTRY PLANTING REPORT.

REVIEW OF "ALL ABOUT ALOE AND RAMIE FIBRES, DYES, DRUGS, &C."—INFLUENZA AND THE COOLIES—LICENSED AUCTIONEERS.

If money is to be made in the by-ways of Tropical Agriculture, it won't be the fault of the *Observer* press, if this is not done by Ceylon men. It matters not what part of the tropics puts on a spurt, and starts in the race of production; nor yet what may be the article grown and dealt in if so be there is money in it, we soon hear of it, and have a Handbook to guide us, should we desire to try it here.

I have before me now one of those pamphlets which belongs to the "All About" series—a collection of useful books which already numbers several volumes, and wherein the enterprising cultivator will find many a workable hint and valuable wrinkle. This *brochure* treats of "Aloe and ramie fibres: dye and tanning stuffs, drugs &c." articles which remain as yet hidden out of sight in the byways of Ceylon agriculture; but which, nevertheless, might be brought well to the front if tackled in the usual energetic way which obtains here. Some of the articles treated of are evidently more suited for the native than the European, but the manufacture of fibre, whether it be aloe or rhea, wants capital, and it I fancy is hardly in their line.

Much valuable information is given on aloe fibre and its preparation in the translation which details the result of the successful experiments in Mauritius; and as the plant there grows well on waste lands, which have been scourged by sugar cultivation, there is no reason for doubting that here too a similar success might be anticipated even on our poorest washed subsoils. The fear usually expressed here, when aloe cultivation is referred to, is, that the weight of the leaves is so great, that their transport—if they had to be conveyed any distance—would eat up any possible profit. The old sugar estates in Mauritius, where the aloe is now grown, are doubtless well roaded, for in Evenor de Chazal's essay this difficulty is never referred to. It is the cleaning of the fibre which had been the obstacle, and when that was got over, success was assured. Ramie or rhea, unlike the aloe, wants, I understand, a particularly rich soil, so as to allow of a succession of heavy crops. But as yet few of us know much about fibre or how best to produce it. The French essayist is very enthusiastic in reference to the aloe; his trumpet gives no uncertain sound, and he encourages his brother planters in Mauritius to boldly make the venture in the following words:—"I will say in conclusion to my colleagues, to my friends, to the proprietors of the coast lands: Plant. Four years are necessary for cultivation. In four years you will have the rudiments of a prosperity well earned. Establish your plantations around your factories so as to take advantage of your network of roads, and do not, in order to try and get returns sooner go and set up your machinery in the midst of a field of naturally grown aloes. The industry is fixed and stable. It is a great mistake to believe that it will be an advantage to render it nomadic. Plant then, and be proud of the progress realized by our compatriots on this Mauritius soil, so liberal to him who knows how to work wisely." Aloe fibre is worth from £30 to £32 a ton, and E. de Chazal gives one and a half ton an acre as the return from his own estate. It looks like as if there was "ile" to be struck, in growing fibre.

The essay of the late Henry Meade on dye stuffs &c., although somewhat hoary,—written about

40 years ago,—is nevertheless very interesting as an intelligent and clear statement of the island's capabilities in those "days of old." The light thrown by the editor in his notes, where he contrasts the production of toddy with what is given in the essay, is very welcome, and cannot but be appreciated by his readers.

There is one thing about this new volume of the "All About" series, that few Ceylon readers will take it up, without getting instruction. It has the charm of freshness, too, as is to be expected, for no established industry is treated of, we hear only of products which can only be found in the byways of Ceylon agriculture, and which require to be sought out to be known.

INFLUENZA among our coolies was a thing we feared. If it were to run through our labour force, especially now when the welcome rains are encouraging the tea to flush, it would put a lot of us out. A day or two ago I heard of one estate where half of the Tamils were laid up, and this not in a feverish district, and it was feared it was the dreaded influenza.

A Licensed Auctioneer and Broker has sent me his business card. It differs from most business cards, in that it possesses a decided "odour of sanctity." The motto at the top is "Quit you like men 1 Cor. xvi (13)" and it is announced as "important to all" that this gentleman is prepared with "easy terms for Christian workers and Mission causes." So far this is good: a further "growth in grace" may lead, let us hope, to the favour which at present can only be claimed by the select few being made free to all. When the gentleman reaches to this sublime height, and sends on a fresh business card to announce it, I would humbly suggest as his motto, "the rain falling on the just and the unjust." PEPPERCOORN.

THE NILGIRI CINCHONA PLANTATIONS.

Large extracts from the Report for 1888-89 will appear hereafter in the *Tropical Agriculturist*. Much interesting information is given respecting Hybrids, the best of which is *C. magnifolia* of which a good deal of seed went to Ceylon during the year under review. Faith in cinchonas has not, therefore, been entirely lost. From the order of the Madras Government we quote as follows:—

Owing to the partial failure of both monsoons, the season of 1888-89 was unfavorable, and the total number of cinchona plants on the four Government estates, on the 31st March 1889, was only 1,709,656, which is 30,488 less than the number on the corresponding date of 1888. The quantity of bark taken during the year was 110,162 lb. but if the store-houses at Naduvatom had not been full, a much larger quantity could have been collected. The total expenditure during the year was R69,494, so that each pound of bark harvested cost 10-09 annas. The expenditure is lower than it has been in any year since 1876-77, and when it is considered that the amount includes the cost of the Quinologist's Department, the result reflects credit upon Mr. Lawson's management. As no bark was offered for sale, save a small quantity supplied to the Medical Stores, and as the manufacture of febrifuge was purposely restricted pending the arrival of the chemicals and apparatus required for the extraction of the alkaloids by the new oil process, the receipts of the department amounted to only R3,602. But a quantity of febrifuge, valued at R2,918, was distributed free, and there was a sum of R2,417 outstanding at the end of the year for febrifuge supplied to the Mysore Durbar.

2. It is observed that the value of the bark used by the Quinologist was R12,396, while the value of the febrifuge produced from it was only R6,385, at R12 per lb. for solid, and R1-4-0 for liquid. These

rates would thus seem to be much too low, and the Government desires to be favoured with the Director's opinion on this point. The loss by leakage was very high—14.6 per cent. Mr. Lawson's attention should be given to this matter and he should report what measures are taken to prevent thefts of the quinine and other preparations now turned out at the factory.

3. Since the close of the year the manufacture of sulphate of quinine has been started, and it has been estimated that it can be turned out for something less than R20 a pound. The selling price will, therefore, be fixed at that rate, but as the present prices of English and German quinine are lower than this, it is not likely that the Naduvatam drug will find a sale among the chemists and tradesmen of India. The present prices of quinine are, however, due to special causes, and as soon as these have been removed and the cinchona market has returned to its normal condition, prices must rise; but meanwhile the Naduvatam factory will probably be obliged to confine itself to the supply of Government Departments. The Surgeon-General with the Government has been instructed to get future supplies of quinine from this source, and Mr. Lawson should ascertain from the Bombay Medical Department whether it is willing to buy Naduvatam quinine, and if so, at what price. This should be reported to Government. It is possible, however, that quinine would find a ready sale at the rate of R20 a pound if it were made up in quantities of a quarter and half an ounce and distributed for sale to village heads and other officers of the Revenue Department. Its value as a febrifuge is well known to the people of feverish districts, and they may buy it if they can get a quarter of an ounce for six annas. The distribution should be made through the Medical Stores, and the Surgeon-General should at once indent upon Mr. Lawson for the quantity that he considers sufficient for experiment. The bottles should bear a distinctive label, on which the price and the amount required for a dose should be stated in English and the vernacular of the district to which the bottle is to be sent. The Board will issue instructions to all Collectors directing them to see that the drug is brought to the notice of villagers, especially in feverish localities.

4. The Director should report, as soon as possible, what quantity of sulphate of quinine and other products of cinchona he can turn out per annum. He should manufacture as much as possible, as the produce of the plantations can be stored more easily in the manufactured than in the unmanufactured state.

5. The Governor in Council is glad to see that Mr. Lawson is making further experiments in the growing of hay. There is no reason why excellent hay should not be grown on the Nilgiris, and it is clear that at present the demand is in excess of the supply. The account of the analyses of the barks of various types of cinchona trees, and the estimate of the yield of sulphate of quinine per acre will be read with interest by planters. The result of the use of solid febrifuge in the treatment of Rinderpest should be reported by the Inspector of Cattle diseases.

6. Mr. Hooper's report is not so interesting as usual, the reason apparently being that the results of much of his work during the year are considered by him to be too elaborate for reproduction in the annual report. They have accordingly been embodied in papers which have been published in British and American Scientific Journals; but His Excellency in Council thinks that a republication of these papers may be desirable, and he desires that copies of them may be submitted for his perusal and orders.

THE COCONUT PLANTING INDUSTRY.

Much has been said and written on the disease now affecting the fronds of the Coconut palm that is disquieting. The preponderance of opinion, as you remark, seems to be that the affection is such as not to cause alarm. Dr. Trimen is reported to have visited an affected estate recently. His opinion on the affection will be looked forward to with interest, and he will possibly be able to say whether the appearance of

affected trees is such as to cause anxiety or not. Meanwhile, it may interest those engaged in Coconut cultivation to know that they are not alone in troubles and anxieties. Mr. Fawcett, the Director of the Botanical Gardens of Jamaica, says, on the disease that is devastating the palms on certain Islands of the West Indies that the disease is present on the palms on Grand Cayman, but not on Cayman Brac. No trustworthy information can be had as to when the disease first appeared. Some say it was noticed 15 years ago, others 40. In Ceylon too people with grey hairs say the spotting of the leaves of the coconut was known to them from infancy. While that is reassuring, it must not be forgotten that what has been in existence for many years may, under favourable atmospheric or climatic influences, assume a virulent form, as with the affections which attacked Coffee here and the Coconut palm in the West Indies. In 1834 the Marquis of Sligo says in a Despatch that the Coconuts on the leeward side of the West Indian Islands were destroyed, but those on the windward side were not affected. It is inferred that the present affection is identical with that of 1834. Mr. Fawcett has noticed the disease everywhere he went, and on trees of various ages. The Natives have been assiduous in their attempts to re-establish their plantations, but have been unsuccessful. The trees get suddenly attacked and die off, even after they have commenced to bear, the foremost and most promising very often being those that are first attacked. The disease travels as often against, as with the wind. The outer leaves first show signs of the attack by turning yellow, then those of more recent growth; but examination showed the seat of the disease to be at the apex of the bud leaf. On cutting through, the heart of the tree was found to be discoloured and to smell and taste sour. The trees attacked showed no signs of either the scale insect or of beetle. During the early stages of the disease no insect could be found on the trees, but during the later stages and after decay insects were present. The affection in Ceylon, so far as it has been written about, seems something different. It is confined to the leaves and is not as deep seated as that in the West Indian Islands. The remedy suggested in the West Indies is to cut down and burn every affected tree where it stands. Mr. Fawcett thinks that "the disease is due to the presence of a bacterium, and it is possible that it may gain access to the tissues through the stomata of the tender leaf buds." It is thought that lime and phosphates encourage the disease, but how we are not told, and the advice is given to dig in cattle manure, or in its absence decaying weeds round the stems. It may be remembered that Mr. Hart, the Superintendent of the Botanical Gardens at Trinidad, suggested the same treatment for the trees affected with the scale insect, so as to conserve moisture at the roots, and in the absence of cattle manure or vegetable matter, salt or brine.—Local "Examiner."

BETEL LEAVES (*Piper betle*) are quoted by Boehringer & Söhne at 5s per lb.! Whether in a dried state or as produced in conservatories is not stated, but we should think the former.

THE BAHAMA PLANTERS are unlucky. One of the worst "weeds" they had to do with—one they could not eradicate—was a certain species of cactus. Now it has been discovered that this plant is valuable for its fibre in paper-making. It is said to be worth £50 per ton. And now a company is being got up to cultivate the very "weed" the Bahama planters have been doing their level best for years to eradicate. This "cactus" is in reality an agave, and it is also being used for the production of Sisal hemp. The plant will grow on arid and worthless land where nothing else will flourish, and perhaps some day Australia will be able to take part in its cultivation in those "desert" areas hitherto unoccupied.—Dr. Taylor in the "Australasian."

CEYLON TEA IN 1889.

WILSON, SMITHETT & CO.'S CEYLON TEA
MEMORANDA FOR 1889.

LONDON, March, 1890.

The amount of Ceylon Tea offered in auction in London between January 1st and December 31st, 1889, showed an increase of about 50 per cent over the supply of the previous year, and realised an average price of 10½d per lb., against 11½d per lb. in 1888 and 1s 1d in 1887, when the imports were but little more than a third of those of the year under review.

Taking into consideration the displacement of a further amount of 19,000,000 lb. of China Tea in the Home Consumption for 1889 by Teas of British-Indian growth, and the competition of the continued increase in the Indian output, this small reduction in the average price for the past year may be viewed with comparative equanimity.

THE TEA MARKET IN 1889.

In tracing the course of the market during 1889 the chief feature to notice is the unparalleled depression, which, commencing in the early spring, remained unrelieved till the first week in July, when, as usual, a reaction set in, culminating in the most buoyant market we had experienced for some years. During the first six or seven weeks of the year, when the lowest grades for price were still ruling comparatively high, and 1d to 2d per lb. dearer than the corresponding class of Indian, buyers commenced to restrict themselves almost entirely to immediate requirements; the arrivals generally at this period shewed a falling-off in quality, and the tendency of the market was towards lower prices for poor to ordinary liquoring Teas, and rather improving rates for those liquors combining strength and flavor. Early in March the demand for the best liquoring descriptions became more accentuated, but the larger proportion of poor and medium qualities continued to fall in value. In face of the heavy imports in May dealers continued to operate in the most careful manner, and throughout June the apprehensions of sellers and buyers, alike, as to the future of the market were such, that good Pekoe Souchongs were selling at 6½d per lb. and the poorest Souchongs as low as 4½d per lb.; the average for everything sold one week at this period was between 8½d and 9d per lb., and some of the poorest invoices were averaging only 6½d per lb. Early in July this downward course was stemmed. The first New Season's Monings had just arrived, and, although of distinctly better quality than the first arrivals of the previous year, they met with a very cool reception, entirely lacking the excitement traditionally connected with the arrival of the first steamer from Hankow. Country as well as London buyers now apparently began to realise the abnormally good values of Ceylons generally, and the stocks that had been accumulating during the earlier months of the year commenced to go readily into consumption, the deliveries for July exceeding those for June by 1,000,000 lb. As the demand increased the quality of the supplies coming forward improved and the advance in values, now well established gradually strengthened. Owing principally to the scarcity of freight the imports during August were exceedingly light, falling considerably short of those of the same month in 1888, the deliveries for that month, on the other hand, shewed an increase of 50 per cent., and afforded ample proof of the sound position of the article at this period. At the commencement of September, however, business was seriously interrupted for a while by the great Dock Strike. The difficulty and uncertainty of obtaining delivery caused dealers to restrict their operations as much as possible, and comparatively little tea was put on the market at this period. On work being resumed at the warehouses the demand at once became more active, and up to the end of October the market gradually hardened, the average price for all entire invoices rising to 1s 2½d per lb.—1d higher than the highest record in 1888. Pekoe

Souchongs and Souchongs, both fine and common, were now ruling quite 80 per cent. dearer than at the lowest point in June. In November the market again began to shew signs of weakness; teas "for price" continued for some little while longer to rule steadily, but the better descriptions and intermediate kinds gradually gave way. During the few weeks prior to Christmas a very flat tone, as usual, prevailed, and at the closing auctions of the year the average price had receded to 11½d per lb.

THE LIST OF ESTATES AND CEYLON INDUSTRY.

This year we have confined our list of estates to those which have sold in auction a minimum amount of 20,000 lb. during the year. Adopting a suggestion made last year, we have on this occasion divided them into four groups, according to the weight of tea sold, and beyond giving the averages realised during 1889, we have (with a few exceptions not recorded) added those of the previous year. We must once more draw attention to the fact that owing to the growing practice of shipping Colombo purchases under fancy marks we have been unable to trace all the produce of certain gardens, and any apparent discrepancies in the yield of any marks is either due to this cause or to the fact that, in some instances, the garden has disposed of a portion of its produce through other channels than those of the London and Colombo markets. In some cases, notably of some well-known Dolosbage marks, we have preferred to omit them altogether, as in these instances their produce during the latter half of the year, when the highest rates were ruling, was sold simply on "garden account" without the mark being disclosed. As far as it is possible, however, we have ensured accuracy, and we trust that the information we have compiled may prove of interest and of some practical use to planters. We venture to think that, on the whole, our statistics afford food for reflection, and not a little ground for congratulation and encouragement, to all concerned in an industry which has arrived at such a wonderful development in so short a time. It is, we think, no exaggeration to say that the development of the Ceylon Tea trade stands unrivalled in the records of all similar planting enterprises. The history of the rise of the Indian Tea industry, with the vast acreage at its disposal, steadily as it has increased in yield year by year, serves only to bring into stronger relief an enterprise which, virtually starting in 1831 with an export of about 300,000 lb., has in its ninth year shipped to the mother country and elsewhere nearly 33,000,000 lb. of Tea, representing a value of £1,500,000. Some idea of this rapid growth, due to climatic advantages and the enterprise of the planters of Ceylon, may be gathered from the fact that in the history of the Indian Tea industry the same result was only obtained after a lapse of more than twenty years.

RESULTS: ESTATE MARKS, TEA SOLD AND AVERAGES
REALIZED.

To revert for a moment to our table of estate results, we would draw attention to a few salient features, which seem to afford considerable encouragement for the future. The result obtained by the first named on the list—Wallaha—will be considered exceedingly satisfactory; at this factory a good deal of leaf is we believe bought, but an increase of 50 per cent in the manufacture is accompanied by a rise of about 10 per cent in the average price. Two of the oldest marks, Maria-watte and KAW, have turned out over 1,000,000 lb. between them at an average price of 11d per lb.; in these two instances the cost of production in the last few years must have been most materially reduced. In the next group the case of Glenugie claims attention; the yield of this estate shews an increase of more than 38 per cent over that of the previous season, and has realised an average price of 1s 2½d per lb., or only ½d per lb. less than in 1888—a figure 2d per lb. in advance of any other estate in Maskeliya. In the cases of Bambrakelly, Ohapelton, Kirkoswald, Labukelle, and numerous others equally satisfactory results may be found, and generally without undue recourse to fine plucking. At the head of each group a great many averages

are noticeable, shewing a substantial increase over the previous year's result. The election of any particular mark is an invidious task, but in the last group the average prices realised by Hoolankande, Portswood, Alnwick, Sheen, Karagastalawa, Bogahawatte, Drayton, and Norwood attract especial attention. On turning to the table of Districts we are at once struck by the fact that three of the highest elevations maintain exactly the same position which they occupied in 1888, while a fourth is within $\frac{1}{4}$ of the previous season's average; the most striking instance is that of Dimbula; this fine district, while securing the same average as in the preceding year, has produced just double the quantity of Tea. Our remarks as to the difficulty of tracing all the produce put on the London market to its original source applies equally, of course, to the Districts, the chief ones to suffer in this respect are, we think, Dolosbage, Kelani Valley, and perhaps, Ambegamuwa. We doubt, however, whether the deficiency would make any appreciable difference in the averages realised according to our estimate. The decrease in the average obtained by Hewahets, which stood first last year, tempts us to lay stress once more upon the necessity of exceedingly careful manufacture of the highest grown Teas, which have no inherent robustness to fall back upon; a good many of the Teas from this district during the past year have undoubtedly shewn some falling-off as compared with the previous year.

CEYLON TEAS IN RUSSIA AND AMERICA.

Last year we ventured to express the belief that Ceylon Teas would soon become better known abroad; we are glad to be able to congratulate planters on the fact that that belief has since then been, to a considerable extent, justified, and we have ourselves received most encouraging support from the Continent—principally from Russia; in fact, during the past few months we have sold the Pekoes of one especial high-country mark principally for Russian account, and have thereby secured much more competition and better prices than we should have done had this Continental demand not existed. The American market remains for the present still outside the pale, but we confidently expect that before long the barriers of prejudice will in this case also be broken down. Reference to the latter market naturally suggests the advisability of making Green Tea. We think it advisable to point out that the demand for this kind of tea is very limited, and is principally for Foreign consumption. Should any quantity of it come forward, we doubt whether the prices would be more remunerative than for Black. As a matter of fact, the Americans do not pay long prices for their Green Teas, and it is further worthy of notice that the latest statistics from China shew that whereas the exports to America of Green Tea remain about stationary, those of Black Tea during the past season shew a very material increase. The manufacture of true Oologs on a limited scale would, we think, meet with a good reception here, but hitherto attempts in this direction have not resulted in a tea of quite the right description; neither the leaf nor the liquor should be green, but should, like the Formosa Oolong, have what is known in the trade as a "high-burnt" character.

WEIGHING AND BULKING.

Since the date of our last Annual Circular dealers have objected to the system of weighing net, whereby they were continually coming into conflict with their country buyers, owing to a proportion of the packages in a break netting less than the customs' average. All teas are now first weighed gross then, if factory-bulked, a percentage is turned out and the tares taken; the average tare is then deducted from the gross to realise the net weight. In the case of teas bulked here, separate tares are taken and similarly separate net weights are assessed. In order to avoid loss of weight under this system, planters should seek to make their gross weights even and a few ounces above a certain full number of pounds; the tares should also be as even as possible, and an ounce or two under a certain full number of pounds. In weighing gross the customs' take no notice of odd ounces, and in taking the tares odd ounces count as a full pound.

SUMMARY OF CEYLON TEA SOLD AT PUBLIC AUCTION IN LONDON between Jan. 1st and Dec. 31st, 1889, estimated quantity in lb. and average prices realised:—

Average Price for the Year 10 $\frac{1}{2}$ d per lb., against 11 $\frac{1}{2}$ d per lb. in 1888.

The initial letters following the estate names refer to the mean elevation, as follows:—

- L (low) sea level up to 1,000 feet
- M (medium) 1,000 to 2,500 feet
- HM (high medium) 2,500 to 3,500 feet
- H (high) 3,500 to 5,000 feet
- HH (highest) above 5,000 feet

FROM GEO. WHITE & CO'S ANNUAL
CEYLON TEA REPORT.

London, March 21st, 1890.

CEYLON.—We have again to record a further marked expansion in this branch of the trade, the imports from Colombo for the twelve months ending 30th June, 1889, being 27,899,000 lb. against 15,614,000 lb. for the previous year. The deliveries kept pace with the increase to the end of March, when supplies being unusually heavy, the stock began to accumulate, until on the 30th June, 1889, it was 8,175,000 lb. against 5,164,000 lb. at the same date in 1888. The serious depression caused by heavy arrivals during April and May (15,600 packages being offered in one day, viz., the 7th May), and the poor quality of many, together with full supplies of common tea from all quarters, forced down the average price of Ceylons in May to 8½d per lb. This low range, though at the time causing much disappointment and uneasiness to those who had tea interest in the island, no doubt had a stimulating influence on the consumption, especially as the greater portion of the China crop—the first shipments of which were placed on the market on the 1st July—was considered by the retailers to be unsuited to the present public taste, as well as comparatively dearer. Although the sales during July amounted to 51,237 packages the largest on record for one month, this quantity was taken at rather higher prices, probably partly due to the news of smaller shipments later on being telegraphed. For the above reason, together with rather light arrivals, and public sales being restricted during the strike, there was a temporary scarcity, and prices, specially for fine grades, rose considerably, followed afterwards by a run on common, until in October very little pekoe souchong was to be bought under 1s per lb., and the average price had advanced to rather over 1s 2d per lb., at which it was maintained during the greater part of the month, the value of some common to fair grades having doubled since May. From this point, in sympathy with India tea, the market became unsettled, with gradually declining prices, first in the case of fine pekoes and broken pekoes, afterwards followed by a drop in the lower grades, the consumption of which no doubt had been, to some extent, checked by the high range established. The general average has therefore receded, and now stands at 10d per lb., but the quality is much inferior to that received last autumn, when it was exceptionally good.

MODE OF SELLING.—The system of selling India Tea on Monday and Wednesday, Ceylon on Tuesday, and both on Thursday, Java following on either day, seems to meet the approval of the trade, as also the omission of ship's name and date of import, so that no alteration has been called for during the past twelve months.

After the serious fall in November, caused by excessive sales on a depressed market, attention was drawn to the advisability of regulating the quantity to be offered both daily and weekly. The almost unanimous opinion being that this would benefit

sellers and buyers alike, a maximum was agreed upon, which came into force in January, and has since been adhered to fairly well. Confidence by this means was given to purchasers, and the market of late years, very sensitive to any adverse influences, was strengthened.

In our annual circular last year, we estimated the total requirements of tea for the season closing 30th June, 1890, at 225 millions, which will scarcely be reached unless deliveries much improve during the next few months. And, looking to the extended use of India and Ceylon for Home Consumption, and that they possess more strength than China, a similar quantity is likely to suffice for the coming season, while an increase in the total export demand is, under present circumstances, not to be expected, it being reported that larger orders than usual have been sent to China for shipment direct to Russia.

We may therefore reckon that for the coming season we shall require:—

	lb.
For Home Consumption, say	190,000,000
Export, say	35,000,000
	<hr/>
	225,000,000
	<hr/>
India will send, say	110,000,000
Ceylon	45,000,000
Java, &c.	5,000,000
Leaving China to supply	65,000,000
	<hr/>
	225,000,000

Now that Ceylon has taken an important position among tea-producing countries, it would be advantageous if, for purposes of comparison generally, crop estimates and export figures could be made up to correspond with the seasons of China and India—say from the beginning of May or June in each year, instead of the 1st October.

MANUFACTURE.—With regard to Ceylon, the quantity available for this market from July 1st, 1890, to June 30th, 1891, for comparison with India and China estimates, will most likely be somewhere near forty-five million pounds. Even allowing that the Deliveries during the past few months have not kept pace with the imports, doubtless attributable to the high prices ruling for the common grades last autumn, and more recently to the uncertainty attending the Budget announcement, still the prospects seem to be favourable to a further considerable extension in the demand (especially if the quality is kept up), brought about by the intrinsic merits of the Teas, and the energy shewn by planters and their friends in "pushing" the sale in this and in other markets.

The scarcity of Teas with fine sterling quality of all growths is already apparent, and they should meet with a good reception during August and September, provided they are up to the standard of those received from India about the same time last year, with every prospect of satisfactory prices being obtained for them until buyers have supplied their wants.

It should, however, be borne in mind by Calcutta and Colombo buyers, when catering for this market that we cannot take an unlimited quantity of high-cost Tea now that "cheapness" is the order of the day. To obviate this, it has been suggested that in sorting invoices of Teas likely to reach this market during the later months of the season, when found practicable, planters should minimise the number of breaks, and instead of making five or six different kinds, should manufacture—say, a first-class Broken Pekoe, and an equally fine Pekoe, but instead of a number two Pekoe, Pekoe Souchong, &c., endeavour to make a useful Pekoe Souchong or "Unassorted," care being shewn to have the leaf as even and wiry as possible, so as to meet the increasing demand for blending purposes or for the packet trade, as well as for export. Pekoe, fannings, when not too small and dusty, and drawing strong, pungent liquors, have sold well during the season just drawing to a close; but if not practicable to make this class, the rough Souchong leaf might be put through an equaliser and classified as Broken Tea.

ADDITIONAL MARKETS.—Further progress has been made in the past twelve months towards developing the use of India and Ceylon teas in other countries. In Europe the special departments for each, at the Paris Exhibition, though under different auspices, did much to bring them, not only before the French nation, but also to the notice of visitors from all parts of the world, while the different Continental centres of trade are pushing the sale of these growths in a steady and fairly successful manner. The result of the efforts being made throughout Canada and both North and South America, although not coming up to the most sanguine expectations of their promoters, on the whole encourages the hope that these countries will, ere long, consume considerable quantities of British-grown tea. Direct shipments to Australasia, for the past nine months, show an increase over those of the previous year, while a much larger trade has been opened up to Bombay, chiefly for transhipment to the Persian Gulf, thus relieving our market of much common pekoe and pekoe souchong, which would otherwise have come here.

BULKING AND PACKING.—We have referred fully to these subjects during the past few years, and there is little fresh to note. Where time and space admit, no doubt bulking at the factory is decidedly advantageous, as the packages are more attractive to exporters, from the leads being uncut, and the Tea, not having been exposed to atmospheric influence whilst being bulked in the London warehouses, consequently keeps better.

Average net weighing has been discontinued, so that tares should, as formerly, be regular, and not show a variation of more than 2 lb. in each break, otherwise the advantage of factory bulking is neutralized as every package has to be turned out here.

Since the strike last autumn the warehouse charges have been increased, and as they are based on the gross weights, according to classes, a saving may be effected by attention to the following scale, viz.:—

Class a. Chests weighing gross, 160 to 199 lb.			
" a. Half-chests "	"	80	" 89 "
" a. Boxes "	"	35	" 44 "
Class b. 180 to 199 lb. Class c. 90 to 129 lb.;			
" b. 60 "	" 79 "	" c. 45 "	" 59 "
" b. 17 "	" 34 "	" c. not exceeding 16 "	

by which it will be seen that a chest weighing 199 lb. is not charged more than one of 160 lb.

MARKING.—On account of its importance, we would again draw attention to the objection there is to putting either weight or tare on the packages; name of garden, description of Tea and chest number being all that is necessary.

ANALYSIS OF CROP.—On the whole, the 1889 crop as proved above the average in quality, and the result will probably be satisfactory to most growers. Some exceptionally choice Darjeelings, Assams and Dooras came to hand, the prices realised for which should encourage the manufacture of fine Tea when practicable. Shipments from Travancore show an increase, and have found much favour with the Trade, as they combine the strength of other Indias with flavour somewhat similar to Ceylons. This district promises to be an important one, as there is a considerable area of land suitable for Tea available, with good roads, which should attract planters. The following table gives particulars as to the out-turn of the 1889 crop from the different districts, of India, and also of Ceylon and Java.

DETAILS OF OUT-TURN OF THE DIFFERENT DISTRICTS FOR THE PAST SEASON.—Quality of the Crop.

CEYLON.—Although the quality was poor, and prices much depressed during last May, the Teas offered from August to November included some of the finest parcels on record, proving that the climate influences the produce of this Island even more than it does Kangres and Darjeelings. Manufacture generally has been more regular, the proportion of overfired and burnt Teas being much smaller.

TEA IN AMERICA.

The tea traders of Boston, New York, Philadelphia, and Chicago are petitioning both Houses at Washington for the reimposition of a tea duty of 10 per cent. They complain that as the United States are the only nation in the world which admits teas duty free, foreign countries have special facilities for unloading on American soil their low-priced and inferior stock. Is tea to be grown in the Southern States, or is this merely an expression of disgust at the efforts to supplant Japan by India and Ceylon? It is a childish proceeding on the part of the tea dealers concerned.—*H. & C. Mail.*

TEA SALES AND DELIVERIES.

On calling at the room of the Ceylon Association on Wednesday last I found it occupied by a number of gentlemen who had been called together to consider certain amendments to be proposed in the procedure of the tea vending trades of London. The meeting being of a private character, I could not venture to intrude upon its deliberations so as to enable me to give you full details as to what passed at it. Opportunity has, however, been afforded me to learn its objects and the result arrived at by it, and these are of sufficient importance to claim first mention in my letter by this mail. Certain difficulties which are now felt by the trade—into the full definition of which I do not feel competent to enter—have for some little time past induced contemplated action. The main one of these difficulties was believed to arise out of the rather lengthy limit of seven days allowed for delivery by warehousemen of tea to purchasers at the auctions in Mincing Lane, and at a conference of a committee of tea brokers and wholesale dealers called on the 7th February last by the request of the Wholesale Tea Dealers' Association it was resolved:—"That the time for delivery of weight notes should be shortened from seven to three days." This resolution was submitted to various bodies concerned with the trade, and at a meeting of brokers held on the 13th February it was resolved:—

"That it would not be practicable to deliver Weight Notes in three days. That, provided the Importers were agreeable, that Weight Notes might be delivered in five working days, allowing ten per cent for missing packages instead of 5 per cent as heretofore. That the Delivery of Weight Notes made up to Eight o'clock on the evening of the fifth working day, should be good. That the delivery of *indirect* purchases should be allowed up to 11 o'clock the following morning."

A copy of this resolution having been forwarded to the Secretary of the Dealers' Association, its Committee on the 21st February passed the following further resolution upon it:—

"That, as a meeting of Wholesale Tea Dealers have already expressed a decided opinion that Tea should not be submitted to Public Sale until it is ready for delivery, this Committee is unable to entertain the Brokers' proposal to deliver Weight Notes within five days of Sale; and would ask the Brokers to consider the subject further, with the Importers, as early as possible with a view of their suggesting some arrangement whereby the Committee may be able to avoid the necessity of advising the Trade to confirm their original intention of only buying Teas which, like other goods, are ready for delivery."

The Brokers again met on the 27th February and took the foregoing into consideration, then resolving:—

"That the Brokers regret that the Dealers do not see their way to accept the proposal made at their previous Meeting, which they considered a reasonable one to place before the Importers for their approval. They are willing to let the 5 per cent remain as at present, but do not see their way to recommend a shorter period for Delivery of Weight Notes than five working days, the Delivery to be up to Eight o'clock in the Evening. The buying Brokers to be allowed until Eleven o'clock the following morning to deliver to their

principals. This only to apply to India, Ceylon, and Java Teas; China Teas, as at present, to have seven working days for Delivery."

Upon this the Dealers' Committee on the 6th March expressed the following opinion:—

"That the proposal made by the Brokers' Association in their resolution of the 27th ultimo be respectfully declined, and that the Association be again informed that the Trade have already instructed this Committee to obtain delivery of Tea on the sale thereof, but with the view of meeting the Brokers as far as possible, the Committee will submit the following proposition to the Trade if the Brokers and Importers are prepared to adopt it, viz.:—That all Teas to be sold on the same conditions, and that Delivery be given not later than three days after the Sale, including the day of Sale, except in the case of the Buyers of China Tea requiring it inspected, when two additional days will be allowed. Missing packages, not exceeding 5 per cent, to be taken if tendered within seven days."

The Brokers' Association not having any further proposition to make, a general meeting of wholesale tea dealers was held on the 14th March, when it was unanimously resolved:—

1. "That, as the circumstances connected with buying and delivering tea have materially altered since the conditions of Public Sale was agreed to, by which seven days were allowed for completing the delivery, and further as an act of justice to buyers, this meeting pledges itself only to buy teas at public sale which are ready for delivery, and on the condition that buyers have the right to cancel the purchase of such lot or lots as are not obtainable on the second day after the day of sale."

2. "That a copy of the foregoing resolution be forwarded to the Brokers' Association, with a request that the conditions of sale be altered accordingly for all tea to be sold on and after *Monday, 31st instant*."

When the receipt of this last conclusion was acknowledged by the brokers, it was pointed out that no time was mentioned on which the delivery should be considered good, and that no provision was made as to third parties, the secretary to the general meeting above mentioned then wrote in the following terms:—

"I thought it was understood that the end of the day, say 6 p.m., would be a good delivery on the second day." The dealers want to secure having the weight notes ready for entry not later than 9 a.m. on the third morning. As regards third parties, they do not enter into the conditions of public sale, which only apply as between seller and buyer."

The discussion of this matter having proceeded thus far, it was thought desirable by those interested to seek the opinion of bodies which strictly represent the growers of tea, and I am sure it will be acknowledged as testifying to the important position occupied by the Ceylon Association in London that it was asked to be the intermediary for further development of it. It was pursuant to such a report being made that the meeting of the Tea Committee of your representative Association to which reference has above been made was called.

As has been written, it is impossible for me to acquaint you with details as to the character of the discussion that meeting adopted. That it was full and exhaustive may, however, be concluded from the list of the names of those gentlemen who took part in it, viz.:—Messrs. G. White and W. J. Thompson, junior, as present to afford explanation on behalf of the brokers; Messrs. Lafone and Champ in a similar capacity as representing the wharfingers and warehousemen; Messrs. Wilson, Seton, Magor, and Tye as representatives of the Indian Tea Dealers' Association; Messrs. Appleton, (of Messrs. Smiles, Appleton & Co.), Teck, Salmond (of Messrs. Moffat & Co.) Sedgwick, and Edwards on behalf of the dealers; and, finally, Messrs. J. L. Shand, Thomas Dickson, Cameron, and Leake as members of the Tea Committee of the Ceylon Association. Following are given the clauses of the

present conditions of sale, the alteration of which were to be submitted to the consideration of these foregoing representative gentlemen, the portions of it to be effected being given by me in italics:—

"The Weight Notes to be ready for delivery within *Seven Working Days* from the day of sale, or the buyer to have the option of refusing to accept such lot or lots for which he cannot obtain the Weight Notes, upon giving a declaration to that effect to the selling broker at the expiration of the said seven days. *Missing packages, if not more than 5 per cent are exempted from this condition, and are to be taken by the buyer at the original price and prompt, if tendered within Fourteen Working Days from Date of Contract.*"

"No allowance will be made on account of any damage which false package, or unequal goodness, found or alleged to be found, after the goods have been taken from the Warehouse."

The meeting was along one, and the tone of the discussion at it at times somewhat warm; but even tually resolutions were adopted of which it is only possible for me to give you the following brief notes, as at the time of my inquiries being made the full text of the resolutions had not been drafted. These will, however, suffice to indicate to you the result arrived at, and will be satisfactory as indicating an addition to the prospect of this much-to-be desired modification being adopted by the trade:—"These teas are ready for delivery, and weight notes will be ready within three working days." "Missing packages (provided equal to bulk)." "To be recommended to Tea dealers by representatives present." These notes of course represent the changes to be made in the existing conditions of sale, and the effect of and result to the discussion may be fully estimated from them. They need therefore no fuller reference by me even if it were possible for me to give it.—*London Cor.*

SCENTED TEA.—We hear that Mr. F. F. Street has imported from China about 60 plants, known there as "Mok Lee," producing a blossom used for scenting Scented Orange Pekoe and Capers and that if he succeed in establishing and propagating the plants in Ceylon he will be prepared to supply to those who intend to make this class of tea.

TEA NOTES.—Sonari, 29th March.—Constant rain with low temperature during past week. Plucking although started on a few gardens has not yet generally commenced. The cold has checked the leaf and much of it is coming out *banji*. Dibrooghar, 20th March.—Nearly all gardens have started to pluck. We had a big hailstorm last Sunday, but fortunately it was unaccompanied by wind, so little or no damage was done. The weather is cold and drizzly. Rainfall up to date 7.53. Darjeeling 28th March.—Very little leaf coming on and what is, opening out. Here is our rainfall since October 25th 1889 to March 25th 1890.—*Indian Planters' Gazette.*

COCONUT BUTTER.—The success of a German chemist in producing butter from coconut oil will be advantageous to the poor of the old world, who have hitherto been the victims of all sorts of sham articles too heavily salted and too unsavoury to be wholesome; the coconut oil is a very pure fat, and when properly clarified has a creamy flavour. A great advantage is that the new butter is being introduced under its own name without any swindling, oleomargarine would have been in much better repute today as a food for the poor if it had not made its first appearance as a swindler. The new vegetable butter has been introduced into several German hospitals, which ought to indicate that from a health point of view it is considered a fair substitute for ordinary butter.—*Adelaide Observer, March 22nd.*

Correspondence.

To the Editor.

PROGRESS IN CHILI:

A NEWS LETTER FROM FALCA, CHILI, S. A.

Falca, Chili, South America, Jan. 16th.

GENTLEMEN,—I believe it is a heavy task to give you some news that may be interesting for the readers of your valued publication. The distance that separates your country from mine, is so large that a long time may pass before these lines reach their destiny. Nevertheless I hope, my news though not very recent will be well received, bearing the character of an international salutation.—The commerce of Chili has got rather important these last years. The exportation of wheat and wine from the southern provinces, and that of nitrate, copper, silver, lead and borax in the northern ones has placed Chili as an important factor into the European market. Still, the importation of foreign articles being stronger than the exportation of national products, all the metallic money leaves the country and we know but banknotes. Chili, with a population of about 3 millions, has more than thirty banks. Our dollar (peso), which has a nominal value of 48 pence, is good only for 25. In a short time we shall have a new man-of-war, called the "Arturo Prat" in honour of our great sea hero of this name. With this new acquisition our navy will get the best of all South America. Taking a map and looking at the shape of Chili, you will see that there is no country in the world with so large an extension of coast, the whole country resembling a long snake being extended from the twentieth degree of southern latitude till Cape Horn. The new vessel is 99 metres long by 18½ large, has 6,800 tons and her velocity is calculated at 17 miles.

The Chilean Government is showing much zeal for public instruction. More than \$5,000,000 is the cost of new schools and lyceums in construction. Every citizen has the right to send his children to school and to the University at Santiago without paying one cent, the Government paying teachers, professors, books, &c. Were it not so as it is, I believe we had fewer lawyers; Falca, a city of 25,000 souls, has about sixty of them and a court of justice with more than a thousand pending processes.

A great number of European emigrants arrived by the last steamers, the Chilean Government having entered into a bargain with an agent for a supply of 30,000 persons. We need so many strange workmen because twelve new railways are in construction, and almost all the Chileans are engaged in agriculture and mine work. The price of these new lines is near £4,000,000.

The good news that arrive mail by mail from the mine districts will contribute to a general melioration of business. Some movement has been observed in sale of actions of mines, in actions of new societies and in rehabilitation of several companies that had lost every credit. We know that several of the last Strait steamers have taken to Europe specimens of metals which were sent with the intention of searching capitals destined to give impulse to several enterprises that find at home neither the necessary money nor the protection they need. Some gold metals figuring among the specimens are of an excellent quality and give good hopes to the mine masters and to the towns situated in the neighbourhood of the mine districts. For the nitrate market an indicoision whose origin is still unknown, is observed,

Should anyone of the *Ceylon Observer's* readers be in want of special information about agriculture, trade and commerce of South America, be sure that I shall have the greatest pleasure in giving them the intelligence they ask for.—I remain, gentlemen, yours truly,

RICARDO PREUSELLE.

CEYLON TEA IN AMERICA.

THE NEW DEPARTURE.

New York, Feb. 22nd.

DEAR SIR,—A matter of great import to Ceylon has just taken place in New York. A very small event here, where such things, the mere opening of another store, are an everyday occurrence, a mere iota in this busy city's daily doings. Ceylon however has very great and grave interest in it. I refer to the opening of the depot of

"THE CEYLON PLANTERS' AMERICAN TEA CO."

Perhaps two-thirds of the citizens of New York never heard of Ceylon. The remaining third probably only from their hymn-books! This has given them most edifying, and valuable, information as to poor Lanka's spices, and her much maligned men, still flourishing I trust, notwithstanding the sweeping condemnation, but tells them nothing of tea.

In order to avoid misunderstanding, and to start fairly, it is necessary to inform you that the American citizens, as I know them, are the most ignorant people I have met. I refer to the New York citizens. "T is true, 't is pity." I have known them now for six months. I have come into direct contact with them, daily and nightly. I have spoken to thousands and thousands of them, on the absorbing question of "Tea." For was I not in charge of the tea kiosk at the American Institute Fair of 1889, from 10 a. m. until 10 p. m. There I smiled pleasantly outwardly, wept and—worse inwardly, and wished I could have murdered whilst I smiled, for I went through a most terrible ordeal. I had no conception that a people could be so woefully ignorant about a daily article of diet, as these people are of tea. "Oh 't is pitiful!" Vast numbers think it is manufactured, and I daresay they are right! for your Yankee can manufacture anything. I must give him that credit. Let us "give the devil his due."

These are the people we have come to save, to teach, to educate and to tell them what tea is; and to induce them to leave the ensilage, which they have been enjoying so long—to drink really pure tea, quite an unknown quantity in this country. To you it will appear a very simple matter to induce them to leave a bad article for a good one. You are mistaken, the task is Herculean. Has not Bunyan described such an encounter against ignorance? Does not the donkey prefer his thistle? Does not the dog return to his vomit? In all fairy tales has not the dear little prince most astounding difficulties to overcome before he is finally victorious over the ogres "Ignorant Routine" and "Egotistic Cunning"? Let us congratulate ourselves that the prince always is victorious, eventually!

Such a combat is about to take place. The combatants have entered the arena. 'T is no puny affair, the combat promises to be severe, but I see British pluck and enterprise is well backed by capital, without which he is helpless, utterly helpless! If capital deserts him he will be done for! The combat in short is a matter of "Time and money." Have I not been skirmishing for six months, don't I know what I am writing about! If the Planters' Company can only afford the funds, if they only have

the capital, success is assured. The store Mr. Pineo has opened has everything to recommend it, the situation is capital, the arrangement inside is most attractive, and the whole work seems to have been most carefully, artistically and economically done. In Mr. Pineo as Manager the Company starts well piloted, for he knows his business thoroughly, has had experience, and has actually gone through the tea mill. He is, too, if not a veritable Yankee, almost one, knows the country and its people not merely well, but intimately. The manner in which Mr. Pineo has started is the manner which experience has shown me to be correct, to wit, *retail*. 'T is mere folly, waste of time and money to attempt to get the grocers to buy and sell your tea. *To begin with*. The grocers are making 150 % on the Chinese and Japanese teas they sell!!! Is it likely they are going in for Indian or Ceylon teas and a comparatively small profit? Philanthropy is *not* one of the commodities in a grocer's shop! I had much converse with the genus "grocer," during the time I was at the American Institute Fair—their conversation was peculiarly "straight," a spade they called a spade. Being in the position I was, 't is possible they considered me one of their own kind. "We don't want your tea, we make a very nice thing out of our teas. Yours may be better, we don't say they ain't, but our customers have been drinking our teas for a many years, and they are going on drinking them, right straight along, so long as we can make them. You bet. No, sir, why should we handle your teas? To make money for you? Rats!!! A day may come when our customers will insist on having your teas, but *you* 'll have to induce them to do *that*, we shan't! When they do insist, why then we 'll talk business about handling your teas, but not now.

The grocer is no fool—and he is one of our impediments.

Not only have we to introduce a new article, and get a nation to change its taste entirely, and to interest itself in something quite unknown to it. Not only have we to fight against ignorant and shallow prejudice, custom and habit which are second nature—but we must kick out the old article!—knock down and smash up the old idol "Oolong." Do you imagine this can be accomplished in a day and without great opposition. Ignorant prejudice, backed by grocery blandishment and aided by the fiend Perquisite, are no mythical foes. People who have dealt with their grocer for years are not all at once going to admit they have been "fooled" by him. Many a citizenesses would sooner go on drinking ensilage all the days of her life than admit *that*. An American can stand anything but *that*. Besides is n't it far more probable that the newcomer is trying to "fool" them? That such is the case our unctuous grocer is careful to tell them! 'T is easy too for the "directors in distress" as Maxwell calls our "lady helps" to ruin your chance with "her folks." She is enamoured of the two candlesticks in the grocer's window, which can be obtained by the purchase of so many pounds of "gunpowder." "Her folks" will drink "gunpowder" for some time.

These are a few of the obstacles we have to contend against in endeavouring to come into contact with the better—? there is no superlative—(*i. e.* moneyed) classes.

To come into *direct* contact with the better (*i. e.* moneyed) classes, is the stepping-stone to success. That is our difficulty. To gain Gould, Vanderbilt, Cæsus *et hoc genus omne!* The mass will follow. There too we shall find our friend the grocer. Thus will the demand be created, wholesale trade will follow. Thus I am confident the demand *has* to be created, to come into *direct* contact

with these people and induce them to *try* your teas, to show them how to make other tea, for this they don't know, and to have a little conversation with them ament it, and to interest them. That is the procedure. Then every pound of tea going to that house is a really telling advertisement. For women here are as loquacious as elsewhere, if possible more than elsewhere, for here they decidedly "boss" the show. This description of customer, the better (*i. e.* the moneyed) class, value the article purchased *entirely* by the price they pay for it. The greater the price, the greater the desire to purchase!!! "Give me the highest priced you have got," two-thirds of one's customers say!!! They glory in showing they can buy the highest priced article there is. If the same tea was offered as twenty-five cents a pound, do you imagine charming Miss Cæsus would buy it, "nasty cheap stuff." Upon my arrival here I considered \$1 per lb. an appalling price—and a mistake. I have "lived and learnt." \$1 is not sufficient. Tea at \$1.75 and \$2 can be got at most grocers. "Your tea ain't as good as Tompkins & Co.'s, but then of course that costs almost double as much and one cannot expect it," simpers Mrs. Ingot. "Is this the *very* best? ain't you got no *peeko* flowers, smelling like oranges, yellow buds like Ma used to buy some at \$2.50 per lb. Was n't it just lovely!" says smart Miss Cæsus as she daintily trips away, quite discontented at having paid only \$1.

These girls are charming, thrilling, enticing, and beautiful exceedingly. They are chatty and free, most independent and business-like, dressed most enticingly and shod to perfection—but, ah me! confiding affection, refinement, and retiring shyness, are unknown to them, whilst a blush has never been seen on one of their pretty faces. Lovely, they most certainly are—but not lovable. Your readers will forgive this uninteresting digression! 'T is as well you should know we have some little pleasure in our lowly calling, that even "handling tea" has some alloy: (N. B. There are two vacancies here.)

Mr. Melville White, in one of his interesting letters, wrote that he was of opinion the only way to educate the people's taste would be by selling a mixture of Chinese and Ceylon teas, in order to gradually wean the people. This at first sight seems a very sensible idea, but not upon consideration. You would thus prolong your education indefinitely, you would have to educate the taste to your mixture. Then—? Having, with just the same difficulty, mind you, that we have now with the pure article, educated them to drink some mixture, you still have to teach them *not* to drink it! but to leave it for your pure Ceylon! Who is going to "finish" this education and when—? Mr. White would have us spend time and money in educating them to drink something which we must eventually teach them *not* to drink! Surely this is a case of *reductio ad absurdum*. No! we must teach, encourage, cajole, and entice, even beg, them if necessary, to drink our tea, but it must be the pure article, nothing less. Let them mix it themselves if they like, we can't help that, but we must never encourage it.

Mr. Murray of Philadelphia wrote something to the same purport as Mr. White, about a year ago I think? Surely he must have seen an abomination known here as the "English breakfast tea." It is a mixture, a nauseate, and I believe a certain emetic. My experience is that the people detest it. "It ain't anything like the 'English breakfast,' is it? because that always makes me sick to my stomach," says Miss Goldenton, with horror depicted all over our pretty face. Yes, we must introduce the *pure* thing, and the only way to do it is a retail business—to begin with,

Such a retail store, so situate—and so attractive as to appeal to the inquisitioners, love of comfort, and taste of the ladies of the upper classes, and through them it will be well and surely advertized from house to house. Every pound of tea so sold and so carried off, by the lady of the house herself, is gossiped about, made carefully (being something quite novel), and whilst drunk with a few friends, doubtless the store with its curios &c. are much chatted about. Could one have a better or more paying advertisement? and do you think it would be so treated if it cost 25 cents per lb.? The ordinary advertisement is as much good as headaches are. Who reads them? Don't they all cry the same—"My" tea is the best? Who believes the cry? Is n't every one tired of death of such things? Besides I maintain they are not applicable to everything—these advertisements.

If one wants to go to a place of amusement, if one wants a horse, a servant, or apartments; one naturally turns to the advertising columns of the daily paper. You can see your apartments—try your horse—select your place of amusement, see the servant's previous characters—and in short are not "buying a pig in a poke." Think for a moment, would you yourself go to the columns of the daily paper if you wanted to buy a pound of tea? At the same time it seems necessary to keep one's name before the public a little. This is doubtless best done in journals and magazines read by ladies—what interest has a man in tea. Daily papers are seldom touched by women, and the women who do touch them are not the women who care for a good cup of tea. The daily paper is therefore useless, but the monthly magazine is taken up again and again, is always about in everyone's way, and before being finally put out of sight in the cupboard your advertisement—if properly placed, and attractive—has probably been seen by everyone in the house—and by callers.

Advertising in this country is terribly overdone. Every theatre programme is given up to it—every house top is bristling with "Castoria"—every post brings dozens of advertisements, and half the men and women who came into the store are advertising fiends. The country fences are panoramic with advertisements. Every cart in the streets is a moving advertisement. Everywhere—everything, everybody—nothing but an advertisement. All with the same only "my things are better than anybody else's." The reaction is now setting in, people are tired of it all, and are refusing to buy because it is an advertised article! The two Malabars are a great attraction at the Company's store. The woman especially, on account of her jewellery I think, as jewellery is always fascinating to womankind. Such an advertisement tells at once, and the two "strange" Malabars, together with the curios, the bungalow in the background, the palms, the photos and finally the "cup that cheers," most carefully prepared in the presence of the customers, all give an attraction positively irresistible to the ladies of New York, and I congratulate Lanka on being so well and ably represented. The only thing wanting to back up so good a beginning is time and money. The more money the less time. If such stores, as the one Mr. Pineo has opened here, could be opened in all the chief cities throughout the States the thing would be *un fait bien accompli* and the householders would reap richly indeed. Apologizing for my ideas on you at such length. Yours faithfully,
McM. CHALLINOR.

INDIAN TEA EXPORTS.

dian Tea Association, Calcutta, 10th March 1890.
DEAR SIR,—The General Committee have the

pleasure to hand you their monthly return of shipments of tea from Calcutta:—

	EXPORT OF INDIAN TEA FROM CALCUTTA :		
	1890 lb	1889 lb	1888 lb
Exports to Great Britain in Feb. ...	5,833,908	4,433,555	3,031,654
Exports to Great Britain from 1st May to 28th Feb. ...	94,963,710	91,260,140	82,583,239
Exports to Australia and New Zealand in Feb. ...	177,049	105,765	6,356
Exports to Australia and New Zealand from 1st May to 28th Feb. ...	3,382,011	2,856,538	2,351,841
Exports to America in Feb. ...	212	12,375	332
Exports to America from 1st May to 28th Feb. ...	164,697	155,784	47,695
Exports to other places in Feb. ...	62,034	97,256	19,609
Exports to other places from 1st May to 28th Feb. ...	1,392,004	854,978	652,738
Total exports from 1st May to 28th Feb. ...	99,902,422	95,127,440	85,635,319

—Yours faithfully, S. E. J. CLARKE, Secy.

TRAVANCORE PLANTERS' ASSOCIATION.

Poonmudi, Trivandrum, March 10th,
The Editor of the 'Ceylon Observer' and 'Tropical Agriculturist,' Colombo.

DEAR SIR,—I have the pleasure to send you herewith minutes of proceedings of the Annual General Meeting of the Travancore Planters' Association, and I trust you will find room for the same in your papers.—I am, dear sir, yours faithfully, J. S. VALENTINE, Hon Secy. T. P. A.

The annual general meeting of the Travancore Planters' Association was held at the Club, Trivandrum, on Wednesday, the 19th Feb., the following gentlemen being present, viz.—Messrs. W. Fitz Gerald, D. W. T. Valentine, D. M. M'ncour, W. Marshall, S. F. Ewart, J. P. Mackay, H. M. Knight, and J. w Valentine, Hon. Secretary.

Mr. D. G. Cameron, the Chairman of the Association, being unavoidably absent, Mr. Fitz Gerald was asked to take the chair till the new officebearers were elected. Mr. FITZ GERALD, in doing so, expressed his appreciation of the honor done him, and was sincerely sorry that the first duty devolved upon him should be to announce the resignation of the chairmanship by Mr. Cameron. The late Chairman had so entirely won the unanimous respect and esteem of the members of this Association, by his zealous and watchful care of the interest of the Travancore planters, that he (Mr. Fitz Gerald) felt confident of giving voice to the unanimous feeling, in expressing his great regret at the unavoidable absence of Mr. Cameron from the present meeting. Mr. Fitz Gerald had much pleasure in congratulating the members of the Association at the very satisfactory reference to Travancore teas, contained in the report by Mr. Hooper, the Government analyst, "On the tannin in Indian and Ceylon teas," and which would be laid before the meeting; and in which South Travancore was specially referred to. Travancore tea was undoubtedly making a mark and a name in the London market, and future prospects were most encouraging and hopeful.

The HONORARY SECRETARY then read the report for the past year. (1) Accounts showing that 21 subscriptions had been paid as against 19 last year and there was a balance in hand of R315. (2) H. H. Government had been asked for a grant to holders of land of 10 per cent over present properties at a fair valuation. The Dewan however ruled that such grant could not be given, so long as "out of the land already granted, a considerable extent in each estate is believed to be still uncultivated." (3) The sum of R4,562-14 had been paid by the Public Works Department on account of planters' roads; but the applica-

tion for a fresh grant, as per list drawn up at last meeting, was still before Government. (4) There had been a good deal of correspondence as to whether Melvarem was chargeable on cardamoms grown on land taken up by planters for that cultivation alone; and it had been decided by the Dewan that this rent should be paid on such cardamoms. This, and the low rates allowed by Government, to say nothing of the very unsympathetic attitude of the Forest Department towards the interests of planters, prohibits them from making this cultivation a profitable business; and those who had unfortunately taken up land for the cultivation of the spice, would find themselves considerable losers thereby: (5) The Madras papers had been asked to give telegrams stating the average price of Ceylon tea for the week, and this the *Mail* had kindly promised to do, but beyond publishing the London market reports which most planters saw the telegrams on tea had not been given. Doubtless the managers of the *Mail* and *Times* would reconsider this.

The HONORARY SECRETARY then having tendered his resignation, the ballot for new officebearers was taken, and Mr. H. M. Knight was elected Chairman, and J. S. Valentine re-elected Secretary for the coming year. Mr. Knight, upon taking the chair, having suitably responded, the following resolutions were passed:—

I. That this Association view the action of the Peermade planters, in having dissolved their Association, with great regret, and considering the limited number of planters now in the country, invite them to reconsider their decision; as it is the more necessary now that we should continue as one body.

II. That everyone knowing the difficulty there is in recovering small debts from kanganyas and coolies in Travancore, the Chairman and Secretary be requested to take legal advice as to the best method of dealing with this matter.

III. That the Secretary be asked to write to Government, pointing out that the share of the cardamoms allowed to cultivators is quite inadequate, and barely pays for collecting the spice; and leaves nothing for keeping the land clear; and asking for a fairer allowance to those who cultivate.

IV. That the attention of H. H. Government be drawn to the damage done to life and property by wild elephants in the vicinity of Mootocoolie, Pinnannaar, Coutapoolay and Culdoorty, that several rogues had become a terror in the neighbourhood of these places; and that Government be asked to give a reward for the destruction of these dangerous animals.

V. A vote of thanks to Mr. Fitz Gerald for taking the chair; and the opportunity was taken of expressing the deep regret with which the meeting heard of his intended departure from Travancore: and with him much success in his new field of life, wherever that may be. Carried unanimously.

The meeting then terminated.

J. S. VALENTINE, Hony. Secy., T. P. A.

INFERIOR CASTOR CAKE.

79, Mark Lane, London, E. C.,

March 28th.

DEAR SIR,—Planters who are in the habit of using white castor cake as a manure for tea and coffee estates will do well to have the quality of such cake tested by occasional analysis.

Genuine white castor cake when pure should contain $\frac{7}{8}$ per cent of nitrogen, and not more than 7 per cent of mineral matters or ash. A full analysis of such a cake will be found in the *T. A.* for 1886 made by myself for the information of planters. A few months since a friend of mine in India, who had been induced to purchase castor for manuring purposes by reading the favourable reports of the writer, thought it desirable to forward a sample to London for special analysis, and the result was so unsatisfactory and the quantity of

dirt and sand so great, that it seems necessary to direct attention to the fact, that although pure white castor cake, when genuine, is undoubtedly an excellent fertilizer, still if mixed with dirt and useless rubbish its value becomes reduced in proportion to the extent that it has been adulterated.

As the manuring season is coming on it may be useful to direct the attention of planters to this matter and if necessary to call in the assistance of the local analyst.—Yours faithfully,

JOHN HUGHES.

(From the *Journal of the Society of Arts* for April.)

INDIAN CATTLE MANURE.

In connection with the interesting paper on "Indian Agriculture," read at the Society's rooms on the 13th inst., by Professor Robertson, the following analysis of cattle manure, as collected from the field (in fact the usual sun-dried bratties used for fuel), may be of interest.

The manure was sent specially from India, and carefully analysed in my laboratory some three years since, and may therefore be taken as a reliable sample, though of course the quality of such manure will vary with the nature and richness of the food according to the pasture fed upon, and the time of the year:—

Water (dried at 212° F.)	...	7.22
*Organic matters	...	65.82
Lime	...	1.96
Potash63
Soda	...	trace
Phosphoric acid54
Magnesia, chlorine, sulphuric acid, &c.	...	5.71
Insoluble siliceous matters	...	18.62
		100.00

From these results it is evident that every ton of such sun-dried manure contains in round numbers the following quantities of the important plant food constituents:—

	lb.
Lime	43
Nitrogen	33
Potash	14
Phosphoric acid	12

102

When such manure is burned, the nitrogen, which exists in the form of organic matter, becomes converted into gaseous products in the process of combustion; but the mineral matters, which include the lime, potash, and phosphoric acid, remain in the ashes, and if these were returned to the land the only loss would be the 33 lb. of nitrogen, equal to 155 lb. of sulphate of ammonia, for every ton of cattle manure so employed.

JOHN HUGHES, F. C. S.,

Consulting Analyst to the Ceylon Planters' Association, 79, Mark-lane, March 17th, 1890.

MR. DRUMMOND DEANE'S GREEN TEAS.

Nuwara Eliya, April 11th.

DEAR SIR,—Some few days ago an "unbiased expert" writing to your paper gave it as his opinion that much would depend as regards the success or otherwise of my "green teas" as to whether they resembled China or Japan greens.

I enclose the report of some New York brokers Messrs. Beebe & Brother made to Messrs. Busk & Jevons of that city to whom Messrs. Rathbone Brothers sent a set of samples of my teas which decides the question as to what class of teas they resemble. Whether these teas will continue to get the fancy prices I obtained for my first break is probably doubtful.—Yours faithfully,

H. D. DEANE.

New York, March 6th, 1890.

Messrs. Busk & Jevons.

Dear Sirs,—We have carefully examined the samples of Ceylon Teas sent us, and find they draw an ex-

ceptionally light water, and generally with a flavour most nearly resembling Choice Japans.

Some of them, notably B No. 1 1856, B No. 2 1857, A No. 1 1851 and A No. 1 1852 are very rich in the cup. Those referred to as "Glazed" are most likely to be acceptable in our market we think, but as the mode of preparation is so entirely unlike anything heretofore shown, the usual difficulty of introducing a new article to the public will have to be encountered. Their most favorable reception will probably be by consumers of the Japan leaf.

We have shown these teas to several of the trade and they invariably pronounce them finest to choicest Japans in the cup, and say they will have to be sold as such.—Yours very truly,
(Signed) BEEBE & BROTHER.

THE SPECULATIVE PURCHASES OF CINCHONA BARKS, upon which we (*Chemist and Druggist*) commented in our issue of February 15th, were repeated at this week's auctions. The same brokers acted for the anonymous investors, and secured some cheap lots for their patrons. Altogether they bought just over 46,000 lb. of bark, at an outlay approximating 900l.

PLANTING IN RAKWANA, March 25th.—Rainfall this month to date 4.34 inches, and as I write another refreshing shower is falling which cools the sultry and close atmosphere, the heat of which has been very noticeable for some days past in the afternoons and evenings. But this is the weather which makes the tea flush. The gemming operations have not so far as they have gone caused "a boom" exactly, but there is no doubt that money is to be made if care is used on the selection of land, and if Government do not by a short-sighted policy check this new industry by the heavy taxation proposed.

FRUIT AND VEGETABLE CULTURE IN SERBIA.—A Foreign Office report on the trade of Serbia is not very complimentary to Servian gardeners. A considerable quantity of fruit and vegetables, it is stated, is annually imported into Serbia, chiefly from Austria-Hungary. The Servians are unwilling and careless gardeners, and with the exception of their Plums and Vines, in the cultivation of both of which there is room for great improvement, neither fruit nor vegetables of any but the poorest quality are produced. Apples, Pears, and Apricots grow in great abundance throughout the country, and there are unlimited opportunities of profit to be derived from their careful and intelligent cultivation. The fruit is in itself of a good description, but through want of attention to pruning, grafting, and manuring, it is, generally speaking, insipid in flavour and small in size, and seems to know no medium between acidity and meanness. There can be little doubt that study and cultivation would make both fruit and vegetable raising a most important Servian industry.—*Gardeners' Chronicle*.

LINNEAN SOCIETY.—At the meeting on November 21st, Mr. W. Carruthers, F.R.S., President, in the chair. Mr. Edward E. Prin was admitted, and Col. J. H. Bowker was elected a Fellow of the Society. Prof. Duncan exhibited and made remarks on a stem of *Hyalonema Sieboldii*, dredged between Aden and Bombay, a remarkable position, inasmuch as this glass sponge had not previously been met with in any waters west of the Indian Peninsula. Prof. Stewart criticised the occurrence, and referred to a parasite on the sponge which had been found to be identical with one from the Japanese Seas. Mr. James Groves exhibited and gave some account of new British Chara, *Nitella batrachosperma*, which had been collected in the Island of Harris. Mr. Thomas Christy exhibited some bark of *Quillaja saponaria* from Chili, which has the property of producing a great lather, and is extensively used for washing silk and wool. It is now found to solidify hydro-carbon oils and benzoline, and thereby to ensure their safe transport on long voyages, a small infusion of citric acid rendering them again liquid.—*Gardeners' Chronicle*.

THE TEA TRADE.

In reviewing the trade returns of the China Treaty Ports for the past year it is obvious to all that the one trade which has suffered most is the Tea trade, the price of this staple having fallen to a previously unknown point and with a formidably lessened trade. Much has been written and said on the subject of the decline of the Chinese Tea trade, but we doubt very much if the root of the evil that has caused this depression has yet been reached. In the report on Tea, 1888, published by the Customs a year ago, Sir Robert Hart comments most unfavourably upon the advice given by many experienced merchants, who after an exhaustive inquiry strongly recommended the reduction of the heavy taxation to which tea was subjected, as the only means likely to preserve the trade, and he concludes his letter to the Tsung-li Yamén with the ludicrous suggestion that the Shan-li, or a paltry hill tax of a few cents, should be removed, and whilst absolutely ignoring the cry for the abolition of the heavy export and likin duties, he goes on to say that he is of opinion that no matter how much tea may be produced by other and duty free countries China tea will always command a market. The fallacy of this argument as regards the greatest market in the world, viz., London is only too clearly shown by the English Customs Returns, where we find the consumption of China Oongou has fallen to a trifle over five million pounds a month, or to less than half of the consumption of a few years back; and it seems that China tea is literally going out of consumption in England, for its rapid falling off has exceeded the most pessimistic prophecies, and it is beyond question now that a few years will see China tea used only in minute quantities to suit the fancy of a few, unless some stimulus be given to the trade, and that can only be done by relieving the producers and exporters of the heavy duties and taxes which weigh so heavily upon them. China can produce, if free from taxation, a fine medium tea to sell in England at 8d to 9d per lb., at which price it would enter most keenly into competition with the Indian article and should undoubtedly hold its own in that grade, providing of course that proper care had been bestowed on the leaf during manufacture, but at present the iniquitous likin and abnormal export duty absolutely prevent the production of good tea at any such price; and when China tea has to enter the market at prices over one shilling per lb., it cannot and never will compete with the Indian and Ceylon excepting in small quantities and as a fancy article. In fact the result of the past year's trade shows that the average price of China tea sold in London is about 6d per lb. showing enormous losses to both native producers and foreign exporters; and the wretched quality of this tea has brought the name of China if it be possible into worse repute than it was before. With a tax in China of 15s per picul on tea the country manufacturer can only afford to pay the grower a trifle for his raw leaf, knowing that the foreign buyer in turn will only pay him for his tea a price at which it can compete with the duty-free Indian, and the grower of the leaf can now barely make a living out of it, much less expend money on replanting his shrubs or manuring and pruning the old ones as he is always being warned and advised to do in the public prints. In fact it would seem that the owners of the once flourishing tea plantations of China are forced to let their plants go to ruin, no encouragement being given them to improve the growth, and are in many large districts absolutely grubbing up their tea plants and replacing them with bamboo. Consequently the quality of the yield deteriorates year by year, the price paid to the grower by the native buyer is in accordance with the quality of the product and the price paid eventually by the consumer continues to fall with the quality. Now if the burdensome duty and alikin amounting to an *ad-valorem* tax of about 40 per cent. on the average value of the exported article were abolished, the peasant proprietors of the tea plantations might be induced to expend some time and money on the improvement of their plants, in the knowledge that were the tax removed, more would be left in the buyer's hand wherewith to purchase

their leaf if of good quality; and it is a recognised fact that good leaf can be produced in China second to none in the world if it only pays the farmer to cultivate it. Let us now look at the share of the world's tea trade that China still retains and compare it with what she has lost, not even allowing for the natural increase in the world's consumption, and we find that only three years ago China exported 290 million lb. of tea whilst India and Ceylon contributed but a little over 80 millions, but in this past year China's export has fallen to 214 millions whilst that of India and the other duty-free producing countries has risen to over 160 millions. A striking example of the difference between taxation and free export, and one that should even appeal to the selfish instincts of the perversely blind Government of China, that apparently cares little whether or no the greatest trade of its people be retained by them or be utterly crushed. To an enlightened government the welfare of its people is of more importance than the mere collection of revenue, unless the Chinese government and those who advise it can be speedily brought to see this, the great tea trade of this country will gradually become extinct. Let the likin and export duties be taken off entirely until the country has had a chance to regain that share of the world's commerce which she has lost, and is continuing to lose through the purblind policy of taxing her principal export.—*N. C. Herald.*

ON THE TANNIN IN INDIAN AND CEYLON TEAS.

By DAVID HOOPER, F.C.S., F.I.C.

[We quoted and noticed the abridgment of Mr. Hooper's valuable paper which appeared in the *Chemical News*, but the details are of so much interest to tea planters that we now give in full the copy which has reached us from the author.—*Ed. T. A.*]

The proximate constituents of tea leaves have been studied and estimated by various chemists with equally varying results and conclusions. The alkaloid therein, physiologically the stimulating principle of tea, has been determined in various samples, but the results have shown that no relation exists between the amount present and the commercial value of the leaf, or the elevation at which the bushes grow. A number of elaborate analyses have been published on the composition of the inorganic matter or ash of tea, but it seems that no useful lessons to the planters can be drawn from these tables.

The tannin of tea has also been investigated, both qualitatively and quantitatively, but as the subject has been treated by so many experts using different methods and applying them to different samples, the results are not comparable and leave the subject open for further enquiry.

Mulder's analyses of tannin in teas are often quoted in text-books; his figures for black tea are 12.88, and green tea 17.80 per cent. Dragendorff found in teas of Russian commerce 9.42 to 12.70 per cent; Janke obtained a maximum of 9.14 and a minimum of 6.92 per cent in eighteen samples; Wigner, analysing some astringent teas, reported as much as 27.7 to 42.3 per cent; Hassall gives as the average 15.24 in black and 18.69 per cent in green teas; Clark found from 5 to 19 per cent; and Geisler, an American chemist obtained 14.87 as the average percentage of tannin in a large number of packages of Indian teas imported into New York.

The interpretation of these figures has been also remarkable. Some isolated analyses have recently gone the round of the Indian papers to the effect that an Indian tea gave 9.68 per cent of tannin and a Chinese tea 6.01 per cent and these figures have been quoted with a view to disparage Indian teas, and to exalt the virtues of Chinese leaves. The teas of Ceylon have also been examined, and from a few analyses it has gone forth that the tannin, as a rule, in the teas of this island is much smaller than in Indian specimens.

Again, tea growers on the mountain tops have used figures to show the superiority of their produce compared with that of the plains, and the following extract taken from a local paper, circulating in a planting community, will show what ignorance is displayed on the subject:—

"The strong rasping Assam brew, and the make of all gardens situated at low elevations, are known to contain upwards of 75 per cent of tannin, while mountain trees are comparatively free from this deleterious ingredient."

The tannin of tea leaves, according to Rochleder, Alasiwetz, and Malin, is allied to quercitannic acid, and according to Kellner is identical with gallotannic acid. It is precipitated from its solution with acetate of lead, forms an insoluble precipitate with gelatin, and inky mixtures with salts of iron; it is associated with gallic acid, boheric acid, oxalic acid, and quercetin, and is the source of the astringency of the tea.

From the numerous methods for the estimation of tannin, the one that commended itself to me was the use of a solution of acetate of lead to a filtered decoo-

tion containing by exhaustive boiling the soluble constituents of the leaves. The process is simple, and it was found to give most concordant results when working on the same sample. The lead precipitate would contain some of the gallic acid and the oxalic acid if any were present, and therefore the weight of this precipitate was an excellent gauge of the astringent properties present: the dried precipitates were found to have a composition averaging 50 per cent of plumbic oxide, a result agreeing with the constitution of gallicotannic acid. The value of the present investigation consists in the observance of the minutest detail in the process being carried out under exactly similar conditions, although applied to different samples. The teas were all air dried, and contained from 5 to 6 per cent of moisture, the green leaves were dried in a water-oven previous to analysis, and the results were calculated upon the leaves containing 5 per cent of moisture.

It will be observed in the above Table that the finest teas are those which contain the most tannin, and there is a gradual declension of this principle as we approach the Souchongs and Congous. The elevation does not appear to affect the amount of tannin as has been supposed. The Dodabetta Estate, the highest in the list, shows a smaller percentage of tannin in the leaf than all the rest, but does not very much differ from the samples from Aratapara, some 4,400 feet below: and in this respect there is very little to learn from the altitudes of the Ceylon teas. The highest tannin content occurs in Travancore tea of Seafeld Estate, a tea of great fragrance, and considered to rank very high-class in the home market, and the Glenorchy broken pekoe of Ceylon, although containing 19 per cent of tannin, is one of the best priced teas of the island. The determination of Nos. 9 and 10 shows that the kind of shrub cultivated in India contains more or less tannin according to its original habitat. The coarse leaves, No. 11, were taken from the lower part of the bush, and were such as are never made use of in the factory. The green teas are very astringent, and as they are made from the same estate as those above, it is evident that some of the astringency is rendered insoluble in the process of manufacture.

The amounts of tannin shown in the list, it must be remembered, are obtained by perfectly exhausting the leaves, and do not represent the amount taken in domestic use. The infusion of the family tea-pot extracts more or less tannin, according to the sample used and the time allowed for the leaves to soak in the boiling water. The brokers' test of five minutes takes out one-fifth of the extract, with a corresponding amount of tannin. The tea-pot infusion of ten minutes removes about one-third, fifteen minutes one-half, and twenty minutes two-thirds. The following experiments were made to show the amount extracted by infusing 1 per cent of tea in boiling water for five and fifteen minutes:—

Tannin.	Extracted		Extracted	
	Per cent.	in five minutes.	Per cent.	in fifteen minutes.
A.....11 08	3.04	27.4	—	—
B.....11 10	4.40	36.2	6.88	56.8
C.....12 32	4.28	34.7	—	—
D.....13 25	—	—	7.88	59.5
E.....13 55	4.60	33.9	—	—
F.....23 50	6.26	26.6	9.52	40.0

The tannin is, undoubtedly, the source of the "strength" of the tea, and the higher the tannin the richer the infusion, and the more of body will the sample possess. Tannin is likewise a natural constituent of the tea, and is not amenable to suppression by higher cultivation, or by the ordinary processes of manufacture. The excellent qualities of Indian teas are accompanied by a higher percentage of this substance, and therefore must be treated as strong teas, either by diluting them with weaker Chinese or by taking a much smaller quantity when required for infus on in the tea pot. If a smaller amount of these strong teas is taken if good water is used for the infusion, if it is allowed to stand not longer than ten minutes we should not hear so much of the "deleterious ingredient" in this universally used beverage.

Ootacamund, India.—*Chemical News*, Dec. 27th, 1889.

MANURES.

Manure is not a mere incident of gardening, an item of small account, for upon an adequate supply of the substance depends whether the garden shall be a success or a failure—the manure heap is indeed the pivot of successful horticulture.

The price of land, and its rental value are now so great, that we can no longer afford to follow the easy slipshod practices of our early history, when a moderate crop gave satisfactory returns for the small amount of labour bestowed, the rental value being of small account. Our gardening of the nineteenth century, to be successful, must take a more intensive character, we must have large and early crops or no profit; small crops and late do not pay.

The soil we cultivate may be capable of producing moderate results without much noticeable exhaustion, but the soil that produces extraordinary crops must have unusual natural fertility, or be handled with uncommon skill, and sustained by high-feeding.

This uncommon skill is afforded by the keen intelligence of the horticulturist, and the high-feeding is obtained by the judicious use of manure.

OBJECT OF MANURES.

To manure the land is a very ancient practice. It was long supposed that the food of such a variety of plants, each with a different chemical composition, are found in the mixed growth of a garden, must necessarily be different—almost as different as the properties of the plants themselves. But agricultural chemists have shown that the food of all plants is very much alike; though certain classes of plants, owing to their economic requirements, must be supplied with specific substances in greater abundance than others. What is good for vegetables and fruit is not always good for flowers, and this results not from the chemical difference between the constituents of the ashes of the vegetables, the fruit, or the flowers, but from the mode of growth of the various plants, and the particular object we have in view in their cultivation. It is not so much the question of the composition of plants, as of the length of time they may have for assimilating food from the soil that is the important factor in a garden.

THE IDENTITY OF PLANT FOOD.

It has been said by Sir J. B. Lawes that if we thoroughly understood the action of the ordinary manures of the farm, and their influence upon our crops, we should be in a better position to explain the effect of any particular ingredient in the artificial compounds sold in the market.

There are thirteen chemical elements in various forms of combination that are generally supposed to be concerned in plant-life. Some are furnished by the free hand of Nature in such quantity, that the horticulturist needs take no thought about their artificial supply.

For instance, in the form of carbonic acid, carbon is contained in the air in sufficient quantity to supply any crop, since their are 28 tons of carbonic acid in the air resting on every acre of the earth's surface. Oxygen and hydrogen are provided in inexhaustible quantity, and in just the right proportions in the form of water. One necessary physical condition of plant-life is moisture, and in the presence of water the chemical requirements of growth so far as oxygen and hydrogen are concerned are fully met. The soil also furnishes several of the other mineral elements in sufficient amount. But there are three constituents—potash, phosphoric acid, and nitrogen—which are aptly said by Professor Kedzie to constitute the golden tripod of plant-life; these are not only indispensable for all growth, but their limited supply correspondingly limits all the other conditions of growth. In manurial value they hold front rank, and upon their sufficient presence in the soil depends successful cropping, both in vegetables, fruit, and flowers. With a sufficient supply of these three ingredients in our soils in active form, there is no limit to production, save those imposed by the physical conditions of growth and season.

DEFINITION OF MANURE.

Manure is any substance added to the soil to increase its fertility by changing its composition, or by affording an increased supply of plant-food.

A complete or perfect manure is one that furnishes all the materials necessary for successful plant growth. The best example is to be found in farmyard dung.

Animal excrements have been recognised from earliest times as powerfully promoting vegetation, and increasing fruitfulness. Dung was the only manure known to the ancients, this being next followed, probably, by the use of chalk, marl, and lime.

On very poor soils it is necessary to make a full return of all the elements of plant-food removed by the crops; but under the high-manuring frequently practised in garden culture, the contributions to the soil may be in excess of the removals, and the land may be increasing in fertility. In such cases a very partial manuring will suffice, a mere stimulant to encourage extraordinary growth being all that is required.

EFFECTS OF MANURE UPON THE SOIL.

Before entering upon the action of the several fertilising ingredients contained in manures, we may mention a few facts respecting their behaviour in the soil. Having already stated that potash, phosphoric acid, and nitrogen are by far the most important elements of plant-food, we will confine our remarks to those substances. The two former, phosphoric acid and potash, are perfectly soluble in water, but when added to a soil, they enter into combination with it, and thus become insoluble.

For example, if a solution containing potash or phosphoric acid be poured on a sufficiently large quantity of fertile soil, the water which filters through will be found, on testing, to be quite free from these ingredients. These retentive power of soils is of great practical importance in plant growth, especially in the restricted area of pot-culture; if it were otherwise, the frequent waterings rendered necessary when limited quantities of soil are used would soon wash away all the soluble mineral salts of the soil, and the plants would starve for lack of nourishment. It has been conclusively proved, however, that if these manuring mineral substances are applied to soils, and for any reason the plants do not take them up, they remain there until they are wanted. It is far different with the third element of plant food which has been mentioned, namely, nitrogen. This substance exists in soils in the form of organic nitrogen, ammonia, and nitric acid. By the action of a minute "bacterium," present in all soils, the organic nitrogen and ammonia are oxidised, and their nitrogen converted into nitric acid. This operation only takes place in moist soils sufficiently porous to admit air, hence the immense advantages of thorough drainage. It is further necessary to successful nitrification that some base, such as chalk or lime, be present in the soil.

Of the three substances then, which constitute the principal food of plants, two are fixed by the soil, while one is liable to be washed away. Nitric acid is said, by Sir J. B. Lawes, to be in a constant state of movement in the land—at one time washed entirely from the surface by heavy rains, and rising again as evaporation takes place under a hot sun and drying winds. As dark-coloured soils absorb the greatest amount of heat from the sun's rays, the presence of a certain amount of humus derived from leaf-mould and other decaying vegetable matters, is advantageous both to warmth of soil, and to nitrification, and a very small dressing of readily available food added to such soils in the form of nitrate of soda, ammonium salts, guano, rape-cake, or even liquid manure, will be found greatly to promote fertility, and to increase the stimulating power of the soil.

We shall hope to continue the subject on a future occasion.—J. J. WILLS.—*Gardeners' Chronicle*.

COFFEE FROM PLANTATION TO CUP.

The latest edition (15th) of this valuable book is just from the press. Additional statistical matter has been added, bringing down the movement of coffee and the exports from leading producing countries to

the present season. Great changes have taken place in the coffee fields of the world. The supply from Brazil has increased greatly since the first edition of the book in 1881, when the average annual production was 229,149 tons for the period 1874—80, against 320,655 tons as the annual average export, 1881—89. Ceylon has almost disappeared as a source of supply. The exports of Sumatra, Java and Ceylon coffee are brought down to 1888; India to 1886. One of the most interesting additions is the comparative table showing the average yearly price of different sorts of coffee from 1881 to 1888 inclusive; it showing a range from 9.7 cents per pound for Fair to prime Rio to 18.11 cents. This volume is invaluable to the dealer in food, for therein is found a description of how tea is prepared, from notes made by the author during a trip around the world, also an account of visits to spice and tapioca plantations, with methods of preparation of those articles for market accurately described; a visit to a citron and macaroni factory, a study of olives and olive oil in Spain; the wine districts of France and Spain; the salt mines of Cheshire; a visit to a model English grocery store. No less interesting are notes of manners and customs in Japan, China, India, Egypt, France, Italy, Spain and other countries. Send for a circular giving contents or better yet, send two dollars and have the book sent by mail postage paid.—*American Grocer*.

ORANGES AND LEMONS.

Those who are interested in the development of the resources of India are making great efforts, by means of selection, budding, and grafting of good sorts, to promote the cultivation of the various kinds of Orange in that country. With the severe competition of Southern Europe, California, Florida, the West Indies, the Azores, and New South Wales, it is doubtful whether any great results can be looked for in the way of exportation, but still the local demand necessitates ample supply.

Mr. Woodrow, in his excellent *Hints on Gardening in India*, tells us that the Orange succeeds admirably in the dry parts of India, such as the Deccan, Mysore, and Central India, but that it does not thrive so well in low-lying moist districts. In making a plantation, the soil generally requires the addition of manure, such as street sweepings, or cow-dung laid on the surface, and then dug 18 inches deep. A crop of Potatoes or Cabbages should be first taken off the ground, and the Orange trees then planted in straight lines, 10 feet apart, among the other crops, and carefully watched during the first year to see that shoots do not come from below the graft; should any do so, they must be rubbed off. The ground should be carefully worked with a variety of crops needing irrigation during the first five years, while the Orange trees are gradually occupying the soil. When the trees are established, watering is diminished from March to May, when the soil is removed from around the roots, cow-dung being placed 3 inches deep in the trench, and covered up with fresh soil. The leaves fall off, and by the end of June the trees are covered with fresh leaves and flowers which ripen into fruit in the following February. A second flowering takes place in February and March, the fruit from which ripens in December; but it is not advisable to let the same tree carry both crops, because it would interfere with the rest of the trees in the hot season. In the accompanying illustration from a photograph of Mr. Woodrow's No. 1 represents the Shaddock, the largest of the Orange-like fruits; No. 2 is the Maloongee, with thick, warted skin; No. 5 is the Mozambique Orange; No. 6 is the Kowla Orange; No. 8 is the variety known as Khaguzee Limbog; No. 9 is the looses-kinned Cintra or Suntra Orange. The other varieties though numbered, are not named in Mr. Woodrow's book.

Dr. Bonavia's promised monograph on the subject of the cultivated varieties of Orange is looked for with interest both by growers and by botanists.—*Gardeners' Chronicle*.

COCONUT LEAF DISEASE.

28th January.

I received the accompanying very cheering letter from Dr. Trimen this evening, and I hasten to make it public: a liberty which I am sure will be excused, considering the importance of the subject. Dr. Trimen visited the estate from which I write about a little over a fortnight ago, and was impressed with the appearance of the affected trees, and was puzzled at the erratic way they were attacked. Individual trees were affected in all manner of soils and in different situations, so that no general opinion as to the unsuitability of particular soils or situation could be expressed. I shewed him two plants standing side by side on a good, free, sandy loam. Their growth was equal; but one was affected, and the other not. He suggested their being photographed. The time at his disposal did not permit of my showing him something more striking. It is a splendid specimen of a young tree just coming into bearing, with a stem two feet high and five feet in circumference at the thickest part. It has a splendid head of fronds, all affected, while the surrounding plants have not formed stems as yet, and are about two or three years behind this one in growth, but are almost free of disease! How is this? In the face of what Dr. Trimen saw. I believe he considered that the theory of malnutrition could not explain the attack generally.

It is satisfactory to have the opinion of so competent an authority that the disease is not communicable; but the appearance of the affected trees and the fact that most of those affected last year are again very bad this year, is cause for anxiety.

Perhaps Mr. Driberg, who has paid close attention to plant food, will be able to say whether a liberal application of ashes with a stimulating nitrogenous manure having saline properties, so as to absorb moisture and keep the soil cool and moist in dry weather will be good, after stirring the soil deep. I suggest a nitrogenous manure so that the trees might be stimulated to throw out fresh healthy fronds to replace those affected. Will sulphate of ammonia do; or will guano answer as well?

I may mention that in March last year I chose out six badly affected trees. To two I applied half a basket of lime each, to two a basket of ashes each, and to two half a measure of salt each. One of the trees treated with lime was pretty free of disease and the other was affected, the same with those treated with ashes, while those which had salt were very badly affected; but the mechanical condition of the soil where salt was applied turned out markedly free, though it was a hard gravelly soil originally. No conclusions could be drawn from those experiments because they were on so limited a scale, and because the results are so contradictory.

I have forked the soil round all the plants of over a half of this plantation with 12 inch forks during the last S. W. rains, and given each plant half a bushel of ashes. It is too early to look for results still.

It will be observed that Dr. Trimen's opinion of the disease is a negative one, *i.e.*, that the disease is not caused by a vegetable fungus. It will be interesting now to have Mr. Driberg's opinion after his closer study of the subject as to what he thinks are the causes at work and what remedies he suggests.—B.—Local "Examiner."

THE JALAP PLANT.

This plant has been figured in several horticultural books under the name of *Exogonium purga*, but recent authorities have referred it to the genus *Ipomoea*. It is found growing wild in Mexico, particularly near Jalapa, and we learn from the *New Guide to the Museum of Economic Botany*, that about 180,000 lb of Jalap are imported annually from Vera Cruz into the United Kingdom alone, statistics which show that the British public have a considerable demand for the drastic purgative. The medicinal properties of the plant are found in the large, fleshy, tuberous, perennial root-stock. The plant when grown out-of-doors, usually

dies back to the root, and the growth is consequently late in forming, so that it rarely flowers well outside in this country. But when the plant is cultivated in a cool greenhouse it is not at all to be despised as a decorative subject, and its twining shoots render it very suitable for draping pillars, covering any bit of trellis-work, or as a rafter plant.

Like most other *Ipomoeas*, it is of easy cultivation, but is most at home when planted out in a fairly rich well-drained border, in a light position, and where it can get plenty of air; under which conditions it will make sturdy floriferous growth, not liable to be affected with insect pests. The flowers produced on rather long peduncles, usually singly, are of a deep rosy purple colour, and midway in shape between a funnel and salver, the tube being about 2½ inches long, and the five-lobed limb about 2 inches across, and they are thrown well above the shiny, green, deeply cordate, acuminate foliage; and the only drawback which they have is, in common with other members of the genus, their short duration, lasting only from morning to night, but keep up a good succession throughout the autumn months. After flowering has ceased, the plants should be trimmed back, and encouraged to make fresh growth early in the season. If grown in a warm temperature, the plant has a tendency to become weedy. A cool airy greenhouse is the most suitable place.—F. R.—*Gardeners' Chronicle*.

BORNEO AND SUMATRA TOBACCO.

The home correspondent of the *Deli Courant* says that the only defect in Sumatra tobacco is its bad burning, while Borneo tobacco burns very white. It is only in this respect that Sumatra tobacco is slightly inferior to Borneo, but Borneo leaf is not fine, neither is it elastic, and it has not that polish or brilliancy which is remarkable in the Sumatra leaf. Its quality is between Deli and Java tobacco and, adds the correspondent, if no better tobacco can be grown there it is not difficult to see how long the planters will continue planting, especially with the expensive labour they are obliged to employ. The tobacco they produce cannot bear comparison with Sumatra tobacco, and is not looked upon by brokers as a possible rival. He further says that Mr. M. Velge, late administrator of Kwaloe Begoeniet, Deli, has returned to England after having gone through British Borneo for the purpose of seeking land fit for tobacco cultivation. Not an acre of good soil did he see, nor has he asked for any concession. The report of his old assistant, Van der Hoeven at present manager of the Amsterdam Borneo Tobacco Company, is, however favourable.—*Pinang Gazette*.

LIBERIAN COFFEE CULTIVATION.

TO THE EDITOR "SINGAPORE FREE PRESS."

Sir,—If your correspondent "Planter" of Oct. 26th will favor us with a call. I shall have much pleasure in answering any questions, or in shewing him photographs of the Estates, and any accounts that may be of interest to him.

The Estates to which your correspondent alludes are manured more or less in the following manner after the first four years are completed:—

- | | | | | |
|----------|--------------|---------------------|-----------------------|-------------|
| 1st year | Tallow cake | ponaac | 1 lb | } per tree. |
| | " | Bones | ½ lb | |
| 2nd year | Burnt earth, | ponaac, | and ½ lb of bones. | |
| 3rd | " | Lime | and lalang thatching. | |
| 4th | " | Any bulky manure | with a few bones. | |
| 5th | " | Same as first year. | | |

The bones cost \$32/- a ton, ponaac, \$11/- per ton procured locally from Messrs. D. Brandt & Co.; Lime \$8/- per ton; lalang the cost of cutting, and burnt earth the cost of making. The expense of manuring including the cost of manure, transport, etc., comes to £5 per acre at the most, the results therefrom being larger and more regular crops of from 3 to 5 cwt. per acre more than from unmanured coffee. Allowing only an extra 3 cwt. this would represent at least an extra profit of £7 per

acre resulting from the application of manure besides the estates being kept in better heart and condition. The acreages mentioned comprise the total acreages that have produced crop on their respective Estates, and not the *finest* portions. Planting 7' 6" x 7' 6" is too close, 9' x 9' give equally good results, and is a much preferable distance. Your correspondent gives 12 to 15 years as his limit of time for such crops. We have coffee 10 years old, and it looks better than formerly and promises an equally good crop next year.

The progress made in the Native States in the extension of Roads, Railways, and the free influx of Tamils have materially helped to obtain the large and progressive results mentioned by your correspondent. The places in which the Estates mentioned are situated have been selected during the course of the last ten years, and every effort has been made to select good soil and suitable localities. I would refer your correspondent to the *North Borneo Herald* of July 1st, as shew-

THE DIGESTION OF FATS.

WHETHER in the polar regions where the sole occupation is fishing, or in the tropical lands of the floating pine, oil is found to be an indispensable food. In the former case it is far more largely consumed than in the latter, but its complete withdrawal, under any circumstances, is disastrous to health. The cereals contain more or less oil; olives are particularly rich in it, and many fruits contain it, such as the coconut, &c. The first food taken by the infant, that is, milk, is abundant in cream or fat. Wherever tissue, change, and growth are found, fat is absolutely essential to the change, and moreover, we find that the more important and highly developed a tissue is, the more fat or oil does it contain. The brain and spinal cord contain proportionately more fat than any other tissue in the body. Another point is, that when the supply of food is insufficient and the body is wasting away, the brain and spinal cord show a proportionately smaller loss of fat than do any other organs in the system. We thus see that fat is in some mysterious way connected with the vital functions and with the most vital parts.

When fat is taken as we take it at our meals, mixed intimately with other food, it is very acceptable, makes digestion more pleasant, and imparts a sense of satisfaction and a degree of strength that would otherwise be wanting. If, on the other hand, it be taken in bulk, and on an empty stomach, then acidity occurs, heart-burn comes on, eructations of fatty acids ensue, and a general sense of distress, of nausea, and even vomiting is felt. We see then that if the fullest benefit from cod liver oil is to be derived in wasting conditions of disease, the oil should be taken as it is always taken in health, as a food. In other words, it should be taken with the food, in the food, and at the time of eating. Physiologists and leading physicians pronounce it one of the foremost advances of our time, and to have revolutionized the old mode of giving cod liver oil. Our forefathers were wont to administer it in bulk, half an hour or so after meals.

The wise physician recognizes the fact that cod liver oil is a food, and that it should be taken the same as all other fatty food is taken, at meal-times with other foods. Pharmacists have been particularly happy in carrying out this scientific idea, and have combined cod liver oil with that most delicious and assimilable of foods, extract of malt, prominent among which may be mentioned one made by the Kepler process. The Kepler Solution of Cod Liver Oil contains a goodly quantity of the oil, agrees well with the stomach, is agreeable to take, and its administration is generally followed by increased weight and improved health, within even a fortnight's treatment.—"Health," London.

ing him the principles that guide our actions in the cultivation of Liberian coffee.—Yours truly,—A. B. RATHBORNE.

Sir,—The letter you have published on the subject of Liberian Coffee Cultivation in the Straits giving, as proof of the adaptability of the soil and climate to its success, a statement showing the splendid results Messrs. Hill and Rathborne have obtained from four of their Estates, is certainly most encouraging to those who would prefer investing their money in Agricultural enterprises to speculations in Tin and other mines. But, such large and progressive results must surely be the effects of heavy manuring, unless the soils on the four Estates, viz:—Linsum, and S'lian, in Sungei Ujong; and Weld's and Batu Caves Estate in Selangor, are exceptionally rich; in fact 'perfect.' As the out-turns of these plantations, being published, are now public property, one is naturally inclined to ask a few questions on the subject, but as they might be considered impertinent and uncalled for, I shall refrain from doing so. On the other hand, however, unless some further information is given to the public as to the cause of their Liberian Coffee yielding such handsome crops, those proprietors whose Estates do not yield the same or an equivalent, allowing for any disadvantages, might fancy that there was something radically wrong somewhere, or that their own land was no Goshen to them, or that they had incompetent men looking after them.

Such being, I should say, the ideas of many, I would venture to hint that the 65, 45, 55 and 12 acres of the four named Estates may be only the *finest* portions of the respective places. It must be borne in mind we are not informed that the above represent the total of the Estates' acreages. To judge fairly the out-turn of coffee, good, bad, and indifferent should be taken into account. Again, I cannot but think that Messrs. Hill and Rathborne manure their places heavily. Closely planted coffee, say 7' 6" by 7' 6" apart, and *heavily manured* would and will give successive crops of from 8 to 12 cwt. per acre *up to a certain age*. By doing so you are simply forcing the trees, overstimulating them, and should you for one year cease the usual refresher you may then think of giving up planting and put your estate down as a non-paying concern.

We are told that such and such an Estate gives so much and so much per acre but we are not informed whether this is actually the results of the soil itself or whether it is the outcome of a highly manured ground. The cost of production is vastly different in these two cases. A man may say to you "Yes, I get my \$10 per acre," but, does he tell you what it costs him to put that on the trees? Does it pay to manure up to a yield of 10 to 12 cwt. per acre? Is it a wise and judicious plan to risk the lives of your plants, your Capital really, to do so? If a Liberian Coffee Estate is properly attended to, and liberally treated with manure every third year, in a soil not overflowing with the "milk and honey" of the essential properties of the earth conducive to the well-being of a coffee tree, and it gives its owner 5 cwt. per acre regularly it will pay him, and will do so for years. As far as my knowledge goes Liberian Coffee, under the above circumstances, is a safe and profitable investment for 12 to 15 years.

In conclusion I beg you will not for a moment imagine I am in any way criticising the information Messrs. Hill & Rathborne have been so good as to let us have. On the contrary I wish them all luck and prosperity, and can only hope that the wave of plenty they are experiencing on their Selangor and Sungei Ujong properties may yet pass over our Johore lands. PARCHMENT.

ORANGE CULTURE IN FLORIDA.

[We have had of late so many inquiries upon this subject, that we are glad to be able to print the following letter. The majority of those who consult us have no knowledge at all of the subject, but still expect to succeed in the business! Ed].

People from the Northern States often ask if a frost may not some time come and destroy the business of Orange culture. Certainly, it may, and so

may the waters of the Atlantic Ocean some day rise and sweep New England from the face of the earth. Danger to life and property all over the world is possible at any time from scourge, pestilence, or the ravages of the elements. The frost danger to tropical and semi-tropical fruits, however, is on a par with the frost danger to vegetables and fruit in the North, only if anything, much less so. No one in the North would hesitate in the buying of a farm, or in planting fruit trees adapted to that climate through fear that some very severe winter might destroy the next year's crop. There is the remote contingency that a severe frost might damage the crop once or twice in a century, but how many times in the last twenty-five years have the Wheat crops and the Apple and Peach crops in the North been seriously damaged? Everything upon the face of the earth has its enemy, but on this account we do not hear of the business of raising Wheat and fruit in the North being ruined or abandoned. There is no doubt of the fact that Orange culture here, in the Orange belt of Florida, is one of the substantial industries of the world, and those who engage in it soonest will take the lead and hold it, as the older the trees when properly cared for, the greater is their bearing capacity. Thus wrote Carl Webber in *The Eden of the South*, and although written six years ago, the remarks given above still apply. And notwithstanding the fact that thousands of plantations of Oranges have been made in Florida, there is still room for more, and a profitable income can be realised from Orange growing in Florida, provided the trees are carefully grown and fertilised. Many owners of Orange groves are totally ignorant of the culture of the Orange, consequently various methods of procedure are pursued by them. One cultivator hoes the ground between the trees to keep down weeds. Another sows Cow Peas (a kind of dwarf Bean used as fodder) to cover and shade the ground between the trees. Others mulch with straw or long grass for a distance of from 6 to 10 feet from the stem of the tree, while others allow the branches to grow low in order to shade the trunk of the individual trees from the sun, and cultivate close to the trees with the hoes. Others trim off the branches so that a horse-hoe can pass under the lowest branches, and thus allow the horse-hoe to be run very near the tree. Some use commercial fertilisers. Others use none, but dig out muck from the swampy parts of the woods, and dig this into the Orange groves. As this muck is a deposit of decayed vegetation which has been forming for ages, it is sometimes valuable as a manure, that is, when a good sample is obtained. There are millions of tons of this manure in the low-lying swampy parts of the woods, and after being made into a compost for a few months, it is found very useful for improving the sandy soils of which much of Florida consists, which are short of humus. The Orange, however it may be treated or ill treated, must feel pretty much at home, for it flourishes so long as it gets a little something besides the ordinary soil.

Budded trees are mostly planted now, consequently a certain approved variety of Orange can be depended upon from every tree, and not a number of varieties as when seedling Oranges are planted. In the latter case Oranges are of all sorts and sizes, and some have thick rinds, others thin; some are affected with the rust mite, while others are clear and bright. It is now the rule to plant budded trees, so that fruit of one variety, texture, &c., can be secured. Budded trees, however, are not so hardy as seedlings, the latter passing through the slight frosts of Florida winters almost uninjured, a slight scorching of the latest and most tender growths being the only damage sustained; but should an unusual frost visit that favoured country, as was the case in 1885-6, budded trees are liable to be greatly damaged by the freezing of all the young wood. The frost of 1885-6, however, did not kill many old or well established trees outright, and every grove affected by the frost of that winter has recovered, and the trees are now in luxuriant health, growing vigorously and bearing good crops. "I am not sure," writes a Florida Grape, Orange, and

Strawberry grower, "whether the said frost was altogether a matter to be deplored, for a vast amount of insect life in the way of parasites must have been destroyed at the same time. Had not this been the case, we Florida Orange growers might now have had a serious task on our hands, fighting mealy-bug, rust-mite, red-spider, and other troublesome pests, which were most likely stamped out by that keen frost."

Unless some very decided and unlikely change in the climate of Florida occurs to cause the temperature to become much lower than it is at present, Orange culture in Florida can be counted upon as a permanent and remunerative industry. All the tropical and semi-tropical parts of the world are being ransacked for varieties of the Orange as well as other fruits likely to succeed in Florida; and it is very probable, writes the same correspondent, that in the course of a few years a greater variety of tropical and semi-tropical fruits will be found growing in Florida than in any other piece of land of its size on the face of the globe.

The Orange trees are mostly planted 24 feet apart each way, and are cultivated in the way each cultivator considers best. Some groves (like English gardens and farms) are in better condition than others; but it often happens that two groves in different sections of the State do not succeed alike, although planted, cultivated, and manured alike, as the soil varies so much in a very short distance; and an Orange grower, like other growers of fruit and grain, finds his first task is to ascertain in what particular variety of plant food his land is deficient, and then to regulate his fertilisers accordingly.

From seedling trees twelve to fifteen years old now growing, writes my friend, in the grove in which I write, 1500 Oranges have been obtained from one tree for the year's crop. Budded trees bear at two years from the time of budding, but it is unwise to allow them to do so. And if Orange growers will only practise a little self-denial, and pick off all fruit as soon as formed for two or three years, with the sole object of first making a fine well-shaped tree, they would find that their acts of self-denial, will be handsomely repaid in a grove of luxuriant trees, prepared to bear a very much greater quantity of fruit at the end of four years than they otherwise would have done had they been allowed to bear a few Oranges each year as soon as the trees commenced to bloom. It is no unusual thing in Florida to see an Orange tree one year old from the bud showing clusters of flowers, and in many cases they are allowed to bear an Orange or two "just to see what they will be," and each year the trees are more and more stunted in growth by this proceeding.

Fine large trees are produced at six years from the time of budding. Some trees at this age attain to a height of 12 feet, and as much though the owner and bear heavy crops of fruit. But a grove of budded trees is a source of anxiety to the owner, since the keen frosts referred to above, and a constant run to the thermometer, is kept up during the duration of cold spell in water.

The frosts usually are three in number during the winter, namely, November, December, and January—one each month, and usually lasting three or four nights; but any one not used to a Florida winter, my esteemed correspondent avers, would say at noon on a day during the prevalence of the "cool spell," "that no such thing as a frost could come here." However, it is the north-west wind which is responsible for any damage done to the trees, the freezing air being brought down by it from the north-western States; and if the wind continue long in that quarter in winter, it is sure to affect the trees much or little. The heat of the sun during this time completely neutralises the effect of the cold, the day being somewhat like a warm day in early autumn in England; but when the sun sets, then the air rapidly becomes cooler, and about 9 or 10 o'clock, P.M., the frosts usually occur.

As to profits of Orange growing there is great diversity of opinion. If the business is conducted as it is conducted by a good many men owning small and moderate-sized groves, there are none. Orange growers

receive by mail all the year round circulars and printed post-cards, as well as business cards in envelopes, containing requests for shipments of fruit from commission merchants in all the Northern large cities, and it has been recently found out that some of these so-called commission men are mere kerbstone brokers, whose furniture and office fixtures are not worth half-a-crown. Of course substantial respectable business men doing a large trade with retail fruit stores as well as street vendors, also communicate in the manner indicated with the growers. But many a hard-working cultivator who has bought or budded his trees, and grown them on for five or six years, working early and late, watching his trees with the greatest anxiety and interest, and delighted to see them covered with bloom, and still more so to see them perfect a good crop of fine fruit, and who sorts and packs and ships it to some of these commission men, who have so mysteriously procured his Christian and surname and address with such exactness, finds himself, as the Yankees say, "badly left." Perhaps he gets a post-card saying the fruit was received in bad condition, and was sold to pay freight; or perhaps he gets 1s. per box, containing from 198 to 250 Oranges, with the advice to be sure and send his Oranges all the way by rail in future, remarking that those received "heated on steamer," having been put on steamer at Savannah for New York. Honest commission merchants—and there are such—do not do this kind of unprincipled work, they usually return 7s. 6d. per box clear, after all expenses are paid.

Some Oranges of course sell better, and fetch better net prices than others, notably the Tangerines, but any Orange grower in Florida who gets an average of 7s. 6d. to 8s. per box clear is perfectly satisfied, and there is money in the business at these prices. An Orange grower who anticipates shipping a crop of Oranges should make enquiries months previously respecting the commission house he purposes to ship his fruit to; and it is much the best policy to make exhaustive inquiries at first to try and find a good reliable man, and having found such a man, to stick to him altogether, even if first returns are not so good as might be expected.

Oranges require careful picking, sorting, and packing. A careless man in packing the fruit allows the long thorns on the tree to penetrate the small sack usually worn over the shoulder and hanging under the opposite shoulder; and when this occurs, and is not detected in packing, the Oranges so pricked usually rot; and if the box or boxes containing these and other Oranges happens to be in the commission man's store for some time, the previously sound ones soon become affected by reason of their contact with the rotten fruit. Sufficient care is not generally exercised in this respect.

Orange growers are now agitating for two things—one is to ship fruit to the Florida Fruit Exchange at Jacksonville, which is endeavouring to ship fruit, and place it in distant markets, with a view to preventing a glut, and ultimately this Florida Fruit Exchange aims at establishing an Orange Auction at Jacksonville, so that the fruit can be sold there, and paid for, without further risk by the growers. The hard nut to crack is how to get Northern fruit merchants to attend the sales. The other question agitated is to sell the fruit on the trees when ripe. If the Orange auction with the Northern buyers on the spot can be accomplished, the second is a certainty. Florida Orange growers have such confidence in the quality, juiciness, and flavour of their Oranges, that they quite believe that the time is not far distant when buyers will call to purchase their fruit at the groves, and I think their confidence is not by any means misplaced.

Grapes, Strawberries, and Peaches, about which I shall have something to say in another paper, also flourish, and pay well for growing in Florida. It is very certain that when Florida becomes better known there will be a greater rush of immigrants thither than has taken place to any of the other States of the Union, and land now selling at from 2 dols. to 25 dols. an acre will be worth ten times more. I may say, in conclusion, that any reader of these notes who contemplates trying his fortune in Florida, and is, therefore, desirous of gaining further additional

information, can obtain it by addressing a letter to Box, 147, Waldo, Alachua County, Florida, and that such information will be cheerfully and truthfully given.—W.—*Gardeners' Chronicle.*

COFFEE IN THE NEW GALWAY DISTRICT

I was down at New Cornwall estate in the New Galway district a few days ago, and it was quite cheering to see the coffee looking so well and if the weather only continues favourable it will give one of the largest crops it has yet produced. The genial proprietor, Mr. Duncan Mullens, deserves great credit, for the successful way in which he has fought the green bug, and practically kept it from doing much harm on his estate. He carefully watched for its appearance and as soon as it is detected he dresses the infested trees with a solution of sulphur, kerosene oil, and carbolic soap, which makes short work of all living insects. This when only a few trees are attacked can easily be applied and is a very effectual remedy, but I am afraid would be too expensive to apply to a large area.—*Cor.*

ROYAL BOTANIC GARDENS, PERADENIYA, IN 1838 AND SUCCEEDING YEARS.

(Continued from page 754.)

The alterations and arrangements necessary for the improvement of the Garden should be immediately commenced with, and the following are the leading particulars that should have attention:—

1. Water properly secured and regulated by drains, reservoirs, &c.
2. The superfluous timber and other trees to be cut down and removed.
3. The plants to be arranged in classical order, and the flower borders properly accommodated.
4. The gravel walks and drives to be put in repair.
5. An arrangement to be entered into for a quarterly or monthly supply of seeds; also for a collection of foreign plants, both to be done by exchange with other countries.
6. Soils of various kinds should be collected and brought together in a compost ground.
7. A glass frame should be made, and fixed to assist the facility of propagation; every means should be used to collect the plants of the Island not hitherto known.
8. A new hortus siccus commenced, and a new collection of the Island seeds made. Apartments should be put in order for the Superintendent with officers attached, specimen and seed room.
9. The Botanical Works should be put in repair, and the latest ones from scientific authors should be provided.

The above work when completed, if improvement and order be kept in view and proceed with each other, will doubtless place the Royal Botanic Garden on a basis, that will enable it to contend for preference with any Establishment of its kind within the Indian Territories.

The advantages to be derived by the public and science in general, from an Establishment of this nature, properly conducted in this rising Colony, requires but little explanation; particularly when it is known that the Island has witnessed but few experiments upon its vegetable productions, that it has also been but little explored and abounds

in plants of very valuable properties, which collected together pursuant to the object of a Botanic Garden would at once give the Agriculturalist and Scientific enquirer an opportunity to discern their true nature, and of ascertaining the distinctive merits of each individual, without the exposure and labour, so discouraging to the progress of deep investigation attendant on penetrating the wild recesses of a jungle country.

With respect to its more immediate good, it may be here perhaps properly remarked, before any just calculation can be made in a mercantile or domestic point of view, of what a certain plant (not a native) is likely to produce in this country, it must be ascertained if the Island is favourable or not to its cultivation. At the Botanic Garden that question should be at once satisfactorily answered, and it will be readily admitted, no source can or ought to possess, better means of arriving at the truth of such enquiry which, the wavering mind of the speculator would very often rejoice to receive.

The natives who are a very dilatory people, and whose principal sustenance is coarse vegetable food, may be elevated to motives of purer industry, by example, in showing them the easy method of producing a superior description of food, which would also be conducive to better health and vigour amongst their great population, and the ultimate good of the community at large.

The demand and great want there is for vegetables, seeds, plants, &c. amongst European inhabitants, as well as natives, speaks much in favour of the utility of such an establishment, and many other are the merits to which it lays claim, for the great accommodation of the public, that may be brought in support of its useful existence, but it is sincerely to be hoped, no more requires to be said to ensure its long and well-supported duration.

(To be continued.)

THE COCONUT TREES PRESERVATION BILL IN THE STRAITS.

We suppose that by [this time the Coconut Trees Preservation Bill has become law. On Thursday last week it was taken in committee, several important amendments were made, and progress was reported. It was, no doubt read a third time at yesterday's meeting of Council. The amended bill is a great improvement on the original. The Government, while not adopting all the suggestions made in the report of the special committee, have adopted some and others they have adopted in a modified form.

According to the original bill, all coconut trees attacked by beetles were to be cut down. This the committee pointed out to be quite unnecessary, as trees attacked by beetles, if properly attended to, recover and become as healthy as ever. On the other hand they drew attention to this fact that every dead tree, whether killed by beetles or not, becomes a breeding place for beetles and therefore ought to be destroyed; and they suggested that such trees should be cut down and either buried or burned. In the amendment proposed by Government a step further is taken. Dead trees are not to be cut down but uprooted, and they can either be burned, buried or submerged. The option of submerging is a good one, as nothing is more effective if properly carried out. Our only fear is that it may not be carried out so thoroughly as burning and burying. But there is another important alteration. All trees attacked by the red beetles are to be treated like dead trees. The red beetle is on all hands allowed to be more difficult to deal with than the black beetle, which has caused so much destruction in Penang and Province Wellesley. Fortunately it is hardly known here, but it appears to be pretty common in Singapore and Malacca, and the Attorney-General, in proposing the amendment, stated that trees attacked by it could not recover, and therefore ought to be destroyed. As will be seen from the report of the proceedings of Council, Mr. Shelford disputed this, and thought there was no necessity of cutting down such trees; but the Governor backed up the Attorney-General and stated that Mr. Ridley, the Director of Gardens and Forests, and some other high authority in the West Indies looked upon a tree so attacked as doomed. This is not exactly a change of front on Mr. Ridley's part, but it is certainly a development of his views on the subject. In this report on coconut beetles published last year, he quotes from a work published by Messrs. Ferguson of Colombo, entitled "All about the Coconut Palm," and apparently adopts the opinions expressed therein. "Many planters are of opinion," says the book in question, "that a tree once attacked by the red beetle should be immediately destroyed, on the grounds that the tree is doomed and the grubs in the tree can then be killed. But a very considerable proportion of the trees attacked recover.

Unless one or more of the grubs bores through the growing point of the base of the cabbage, or sets up decay in the heart of it, the palm has a very good chance of recovery. At the same time a tree once attacked is usually liable to further attacks from both kinds of beetles, and unless it is really a valuable tree, it is perhaps hardly worth attempting to save it." This, we think, points to the fact that it certainly is not impossible to save a tree attacked by red beetles, though it may be difficult and so little worth the trouble and expense as to make it advisable to cut it down. We are inclined however considering the value of coconut trees, and the length of time they take to grow, to think Mr. Shelford's view of the case the right one.

The committee's suggestion that people whose calling necessitates the use of material likely to become breeding places for beetles, should require to take out licenses, and that all others having such material on their premises should be prosecuted, does not appear to have met with the approval of the Government. No notice is taken of it. The suggestion, however, to extend to all officers of the Gardens and Forest Department and to the District Officers and their assistants the powers originally given only to the Director of Gardens and Forests, of entering upon lands and places likely to harbour beetles, whether adjacent to coconut plantations or not, has been adopted. This is most important—perhaps the most important part of the measure; for while decayed coconut trees no doubt harbour a large number of black beetles, the number bred in dungheaps, manure heaps, and paddy fodder is infinitely larger, and the destruction caused by them much greater. It is most important too that not only adjacent lands and premises are named, but all lands and premises in the Colony where beetles are likely to breed; for it is beyond doubt that they breed in places miles away from the plantations in which they cause such havoc.

The bill, as amended, is, we think, likely to have an excellent effect. That strong measures had to be taken to prevent the terrible destruction of coconut trees by beetles has long been apparent, and the provisions of the bill, which no doubt was read a third time yesterday, if properly carried out, are admirably calculated to do so. —*Penang Gazette*, March 7th.

THE HOME TEA TRADE.

Once more have we had proved to us, how useful the Ceylon Association in London may prove to be to the interests of this Colony. It may be said that its latest endeavour to serve has had but an indirect bearing upon the business of our tea planters, and that the action reported by this mail has a more direct reference to the procedure of the Home trade; but nevertheless it will, we think, be admitted, that every change in the way of improving that procedure must beneficially affect the results to planting operations here. We have before adverted to this topic at the time when the question of "prompt" had been under consideration by the Tea Committee of our representative Association in London. When we did so on that occasion, we did not fail to deprecate any sudden or great changes in the course of home trading in tea. We pointed out, what was manifest to all as the result of the discussion which took place on that subject, that any course which was liable to greatly disturb the procedure as then established, must, in consequence of the wide ramification of the agencies by which our tea is distributed throughout the United Kingdom, necessarily be deprecated.

The changes that are now proposed seem to us, however, scarcely likely to need inclusion in this category. If made as the result of the recommendations agreed to, they will benefit rather than injuriously affect the position of the general dealer

in tea. We believe—although the opinion finds no expression in the report sent to us by our London Correspondent—that the action now taken has been indeed with the object of checking an evil tending to produce those sudden and violent fluctuations in the price which have told so unfavourably on the interests of tea-growers, not alone in the case of those of Ceylon, but of those of India as well. This evil consisted in the practice of many brokers of having printed in their catalogues an enormous number of entries for sale which were almost of a fictitious character. At all events the supplies to which they referred were in so indeterminate a position as regards readiness for delivery, that it frequently happened that a large bulk of the tea advertised as for sale in those catalogues had to be withdrawn on the morning of the day fixed for the auctions. The result was that buyers attending the sales, in consequence of directions received, but the day before or so from their constituents, entered the sale-room with the vaguest possible ideas as to how far dependence could be placed upon the list of supplies advertised for their competition.

It is easy to see that the limit of seven days allowed for delivery greatly fostered this injurious practice. It was sufficiently long to afford to the selling brokers a chance of having their lots ready for delivery in cases where no such readiness existed upon the day of sale, and this chance disposed them to rashly enter in advance large stocks for competition which, when sold, it often became impossible to deliver within the limit of time allowed. The proposed restrictions of this limit to three days instead of to seven as at present, must certainly make brokers more cautious in offering at auction lots as to the delivery of which they can feel no assurance; and it must, we should say, result that if the restriction be adopted the advertized lists will hereafter be confined to such offerings as to which there may be a certainty, or comparative certainty, of ready delivery. We can all see that so long as doubt in this important particular exists, it must often have the effect of cramping the bidding at the sales. The other points dealt with by the Association Tea Committee are matters of but minor detail necessarily arising out of the proposed change and intended merely to safeguard its operation. Into these, therefore, we need not now go; as it is with the principle only which embodies them that we are now concerned.

It certainly speaks highly for the efficiency and influence of the Ceylon Association in London that it should have been chosen by the brokers, dealers, wharfingers, and warehousemen, concerned in the Home Tea trade as their intermediary in this important matter. This fact reflects credit upon Mr. Shand's discrimination when he urged his proposal at the last general meeting of the Association that a Committee should be appointed to deal exclusively with the single article of tea. What that Committee has already done in our local interests affords sufficient evidence of the wisdom of the appointment of such a Committee. Consisting as that body does exclusively of experts in the tea trade engaged in daily business in the City of London, it can be readily called together to consider questions such as that with which we have been dealing and cognate subjects. The gentlemen who compose it are in daily association with all those who are in some form or another engaged in tea vending operations, and they must therefore necessarily become well acquainted with all the details of these, and with such shortcomings in them as it is desirable should be amended. Although various interests concerned have expressed

the view that the proposed limitation is incapable of adoption, we have no doubt that the concurrence of opinion expressed at the meeting will in the end override such objections, and that what seems to us to be an important improvement will eventually receive general approval.

Since writing the above has come the good news of a reduction of 2d in the imperial tea duty, which cannot fail to give an impetus to the tea trade of the United Kingdom.

THE RUBY MINES.

A RUBY MARKET TO BE ESTABLISHED.

We have now an authoritative statement of Sir Lepel Griffin's views on the Ruby mines. "The visit of Sir Lepel to the mines was satisfactory," declares a public statement, "and Sir L. Griffin considers that it has resulted in placing the affairs of the Company on a more assured basis. The great difficulty of the Company was smuggling. No good rubies reached the Company's agents under the existing rules, which compelled the miners to dispose of stones to the Company, or sell them by public auction, paying the Company 30 per cent. on the valuation. With the approval of the Government the existing rules will be abolished, and a free market for the sale of rubies established by a limited number of miners, who will pay fees estimated to produce £15,000 yearly. No fresh native mines will be allowed to be opened. As a result of these changes all the detectives, and three-fourths of the Goorkha military police, will no longer be needed. Sir L. Griffin considers that the expensive and elaborate hydraulic methods of Californian mining, which it was originally proposed to adopt, are unsuited to the Ruby mines. He declares that the enterprise, if carried on with energy, will be a brilliant success, but much remains to be done before the Company will be in working order.—*Echo.*

THE RUBBER TRADE.

In a recent number of the *Guayaquil Globe* is an excellent article on "The Cultivation of Indian-Rubber." It reads as follows:—

A cablegram that we published recently proves that the merchants and bankers of New York consider it probable the manufactories of rubber goods will close, owing to the lack of shipments of India-rubber from Brazil. On a small scale Ecuador is also a rubber producer, and as it is certain the price of the article will continue to rise in the manufacturing centres, we wish to call the attention of our agriculturists and enterprising citizens to the fact that rubber crops offer good returns, and that farms should be for the growth of trees which are easily cultivable, require little manual labour and yield good returns.

The system we have followed up to the present has stripped our forests of the rubber trees, and thus we have killed the trees which formed the hen which was giving us truly the golden egg—although it is a thoroughly understood and well-known fact that by periodical tapping the rubber trees a certain crop is insured, while the trees do not die. Up to now our cutters have chopped down all the trees near markets where the rubber could be sold, and thus, in order to obtain the article, they have to wander far into the innermost recesses of our vast forests in order to obtain, with their axes and machetes, sap from which to make the rubber. For this reason, the nation which owns the forest should adopt measures to prevent the destruction of the remaining trees, and should protect and assist by all possible means those who undertake the establishment of rubber farms.

Ecuador is essentially an agricultural republic, and for this reason we must seek, in our soil, the means of augmenting our national wealth. We sincerely hope these indications will receive attention at the hands of our citizens, the Government and the Legislature, which will soon assemble.—*Electric Trades Journal.*

THE GREAT "TEA" QUESTION.

Two or three things combine at the present moment to make the subject of tea and the tea market possess more than ordinary interest. To our readers the forthcoming season and the demand that is likely to be required from China will be of peculiar interest. Unfortunately, there is no disguising the fact that the outlook is very far from encouraging. That there will always exist a certain demand for a quantity of China tea is inevitable, for there are people who will not drink any other. They rightly object to the extra percentage of tannin found in Indian and Ceylon teas, whilst the aroma of the better class China teas is lacking in the more pungent and darker liquids brewed from its rivals. Still, this class of persons is limited, and medical discrimination has not gone very far as yet in prescribing China tea for invalids in consequence of the smaller tannic properties that it possesses. For the main bulk of the lower and middle classes, particularly amongst the labouring and artisan sections of the community, there is no doubt that Indian and Ceylon teas are preferred, because from the stronger infusion a pound of tea does go farther, and quantity more than quality counts with them. This fact also appears to be the solution of what at first appears extraordinary, viz.—that though it is generally known more tea is drunk, the statistics of actual pounds do not show any augmentation last year, the total home consumption being 185,622,000 lb against 185,434,000 lb. in 1888, and 183,636,000 lb. in 1887. As Messrs. Geo. White and Co. point out in a circular we quoted in our last issue, the explanation may probably be found in the greater strength possessed by the teas of India and Ceylon over those of China. In fact India and Ceylon, as compared with China, is "over proof," which, no doubt, is a great reason for their popularity in the eyes of domestic economists. As for the coming season the demand is likely to continue in the same vein. We have already unfortunately had to state that the orders from the home market for China teas given to the buyers before starting have been almost nil. For Russia, on the contrary, they have been very large, and many of the English buyers have secured very fair orders from Moscow. But for the English market it will be found that 65,000,000 lb. to 70,000,000 lb. of China tea will amply cover all the requirements. India, it is estimated, will supply 110,000,000 lb., Ceylon 45,000,000 lb., and Java, &c. 5,000,000 lb., which will make up the required wants for home consumption and export.

Another phase of the tea question is being sedulously worked at home just at present. It is quite usual at this period of the year to have as large amounts in bond as possible, in view of an expected, or hoped for, reduction of the duty when the Chancellor of the Exchequer makes his annual statement. How much the wish is again father to the hope we cannot presume to say. It is known that a considerable surplus will exist, but it is unlikely, as far as one can judge, that this duty will be altered. However, the matter is being ventilated, as far as possible, by those in favour of it. The Cobden Club are busy issuing pamphlets, &c., on the matter, and Mr. Picton has secured first place for Friday, April 11th, for his resolution in the House of Commons:—"That in the opinion of this House the Customs duty on tea ought to be abolished." Every person in the population consumes, it is estimated, a pint of tea per diem, and that, next to bread and sugar, it must be considered as a necessary of life. The average tax on its cost is 75 per cent, and whereas tea can be purchased at the average price of 8d per pound, it can be bought as low as 4d, or as high as 2s or more, and as both and all classes pay 6d a pound, it results that the poorest classes pay 150 per cent and the better classes 25 per cent. Of course, the Cobden Clubites seize on this, and point out the peculiar hardship with which it bears on the poor. They work out figures to show that the agricultural labourer, whose pay is say, 13s a week, renders one whole week's wages in duty for tea in the course of a year. That these facts will doom the tax as it exists, or lead to discriminative duties for various classes of tea, is, however, extremely doubtful; but the question will in part be decided, we presume, on April 11th, if Mr.

Picton secures a hearing. It is scarcely likely, however, the Government will readily give up a tax which yields over four millions and a-half annually in so easy a manner.—*L. & C. Express*, March 28th.

PLANTING IN TRAVANCORE.—We call attention to the instructive account given of his visit to Travancore by Mr. H. D. Deane, and we are pleased to learn that there are so many signs of a revival of prosperity and of success in tea and other products among our neighbours over the way.

INSECT PESTS.—What are we to say in Ceylon after the following from a Colonial journal:—"It has been estimated that the annual loss to the United States by insect pests amounts to the enormous sum of \$150,000,000, and that the loss to cotton plantations alone reaches \$15,000,000." What scope for the inventiveness even of Americans to fight these pests!

PEPPER CULTIVATION IN PERAK.—From the report on Taiping for December, we quote as follows:—"Walked up to Pasir Panjang with the District Engineer, and visited Syed Musa's pepper plantation; Government have advanced up to date \$2,890 on account of this estate. Sixteen acres are being opened up, and nine orlongs (twelve acres) are already planted with pepper. I did not count the vines, as this was done in October last by Mr. Wise who reported that there were about 8,000 growing; about 25 per cent of those planted having died owing to the wet. Syed Musa has now however, adopted a more satisfactory system of drainage, which will no doubt tend to decrease this percentage. In the nurseries there are over 6,000 vines, but these will not be ready for putting out for some months. In the clearing first opened the vines are about twenty months old, and a number of them are coming into bearing. Nearly all the vines in this block are planted against *dedaps*, but by way of experiment, a few were put in against hard-wood posts. These latter I noticed were far in advance of the others. Syed Musa has now let contracts for the supply of 3,000 hard-wood posts, which he intends using in future in preference to the *dedap* trees.

THE ANNUAL MEETING OF THE INDIAN TEA ASSOCIATION was held in Calcutta on the 7th instant. The chairman, Mr. J. N. Stuart, referred in his speech to coolie recruiting, which, he said, had received a large share of the committee's attention during the last year. With regard to the abuses in the present system of recruiting the committee were of opinion that if the free *arkutti* coolies were not allowed to be put under agreement at Dhubri some of the abuses might have been disposed of. A suggestion to this effect was made to Government in April last, but an inquiry was then going on with regard to the working of Act I. of 1882, and Government did not see their way to adopt it. Since that time, on the report of the Assistant Commissioner of Assam, Government had decided to abolish Dhubri as a labour district. It remained to be seen whether the alteration of the working of the Act would have the desired effect. He thought it was generally known that the abuses in recruiting which excited so much attention this time last year had gradually abated, and that the state of things at present could be described as satisfactory. This result was largely due to the energy and tact displayed by Mr. Tucker, the officer deputed by Government to inquire into the state of affairs. The attitude taken by the Association was instrumental in bringing about an improvement. The *arkuttis*, finding that their method of binding coolies did not meet with the approval of the Association, were forced to adopt more honourable means of procuring labour. Amongst the resolutions adopted was one increasing the rate of subscription from 9 pies to one anna per acre under tea cultivation.—*Times of India*, April 10th.

COCONUT LEAF DISCOLORATION AND
ALLEGED DISEASE) IN CEYLON.

The Editor, *Tropical Agriculturist*, Colombo.

Colonial Secretary's Office, Colombo, March 20th.

Sir,—I am directed to forward to you the enclosed reports made by the Superintendent of the School of Agriculture on the coconut leaf disease in Ceylon.—I am, sir, your obedient servant,

R. A. BROHIER,
for Colonial Secretary.

KANDY, April 20th, 1889.

I beg to report that I visited Veyangoda on the 27th March, spending part of the 27th and 28th in enquiring into the subject of the 'disease' affecting the coconut palm. In certain areas in Veyangoda I observed that the trees were in a very backward condition—looking sickly and parched. I brought away with me leaves from affected fronds, and examined the discoloured portions of these leaves under the microscope at the School of Agriculture. [This instrument was neither complete in its fittings, nor powerful enough for the examination of minute fungi.] I was, however, able to discover a parasitic fungus in the specimens I brought away with me.

I had hoped to be allowed sufficient time to carry on my enquiry into the subject more thoroughly than I have done, using what intervals of time I had to spare, and availing myself of extraneous aid offered me in the matter of getting at better microscopic appliances.

I have, however, been able to visit districts where coconuts are cultivated both far from, and near to, the coast, and to note the different modes of cultivation and treatment of the soil adopted in the various plantations; and I have no hesitation in saying that thorough cultivation is the surest way of combating the evil. Where the trees have been helped to maintain their vigour the affection was at a minimum, and in places where I would have expected to see the trees badly affected, but where as thorough cultivation as one would have expected to find in the best agricultural districts in England, was adopted, there was hardly any indication of the 'disease' to be noticed. In areas where the attack was at its worst the soil was generally not in a condition favourable to luxuriant growth. A favourable chemical condition of soil is correlative to a good mechanical condition produced by working, liming, draining, &c. Thorough, deep cultivation must be adopted in soils inclined at all to be heavy—even at the risk of temporary loss, followed by liming—and if necessary—manuring. Deep draining is especially necessary for heavy soils. No one who has seen these operations carried out under necessary conditions, and seen their results, can doubt their efficacy in preventing those conditions in the crops grown which favour attack from fungoid and insect pests.

Now in enquiring into the cause of a weakly growth, I would enquire first, whether good "seed," from a healthy and well-developed stock was used, whether the planting was properly done, and whether the crop has been well treated. It is difficult in the case of a perennial like the coconut, to get at the remote antecedents of the plant, but to any one coming from a country where the art of agriculture is practised to perfection, the niggardly treatment of the soil, and especially coconut soils, in the generality, is most striking. Where the advantages of a fallow or a rotation are shut out, it behoves cultivators of coconuts to use every artificial means of maintaining the fertility of the soil. As exceptions, I have seen coconut estates under a very perfect system of cultivation, and as I mentioned before, they showed no indication of suffering from 'disease'—the plantations were, moreover, on a comparatively stiff soil, and at a distance from the sea. I cannot agree that salt, and salt only is necessary to raise the affected coconut tree to a healthy state, but I do not mean to underrate the value of salt in coconut cultivation; and I may here state

that a supply of salt under easier conditions, but with what precautions may be thought proper to preclude it from being used for culinary purposes, is a great desideratum. But it must be remembered that the use of manures must follow cultivation of the soil; and in heavy soils, without thorough deep draining, the advantage of manuring are nullified. Then all these operations so necessary to a soil continually growing the same crop, must be regularly and systematically carried out, not in patch-work style. No experiment is required to prove their necessity. Results must be waited for: it will take time under the effects of previous ill-treatment.

An outlay of capital is, of course, necessary, but the increased returns, and the resultant vigour of the tree—enabling it to withstand attack, will more than repay this outlay. C. DRIEBERG.

SUPPLEMENTARY REPORT.

In sending out this Supplementary Report on the Coconut Leaf Disease question I need not apologise for the delay in its appearance, for those who understand the nature of such an enquiry will admit that it must be based on close observation, and entail time sufficient for examination of leaves and of soil, for watching phenomena as they occur in time, for observing the effect of changes of climate and temperature, for enquiring into the history and progress of the plantations, and gathering a vast amount of information regarding various estates. I have spent much time in this, but no more than was necessary to enable me to come to the conclusions I have arrived at. During the past nine months I have, through the courtesy of estate proprietors and lessees, been enabled to visit a number of estates with the object of making observations, and of gathering information which they were only too ready to give me. I take this opportunity of recording my gratitude for the help they have afforded me in this way.

But perhaps I owe an apology to many who will read this report for entering too minutely into the chemical aspect of soil, cultivation and plant-growth. Many who are perfectly conversant with the facts.

Since my first report, however, questions in this connection have arisen in the columns of the daily press, and discussions have been carried on on agricultural chemical subjects, involving points that were scarcely fairly stated. I had neither the time nor the inclination to take part in these discussions, but at the same time, feeling it my duty to in some way help towards the clearing up of some of the points that have arisen, I take the opportunity of expressing my views and the authorised opinions in support of those views, in this report, for, as a matter of fact, the questions at issue are closely connected with the subject of the proper cultivation of coconuts.

I have endeavoured to summarise the discussion as much as possible, and at the same time to note the weighty opinions of men who have had long experience in coconut cultivation: and the conclusions I have arrived at are, as I hope to show, in accordance with the ideas of both practical and scientific men of repute.

Public attention was first drawn to coconut leaf-disease in Ceylon in a letter from the Veyangoda correspondent to the "Examiner" in its issue of the 31st January 1889, when it was thus described:—"It (the disease) is first observable as orange-coloured spots on the leaves. No fungoid growth is observable by the naked eye, only the discoloration of the leaf. As time wears on the orange coloured spots dry up and are of the colour of withered leaves. Some fronds are so severely affected as to die off, and in these an ashy substance very like fungus is observable by the naked eye." Specimens of leaves with the disease were forwarded to Dr. Trimen, Director of the Peradeniya Gardens, who, after a cursory examination gave it as his opinion that "their appearance suggests a failure of proper nutrition:" he would "look to the roots and the soil for the cause." "I cannot but think" said Dr. Trimen "that these (plants) are being grown under some uncongenial conditions.. ." "one requires to know the history and surroundings of the plants themselves and watch their progress

for some time." The Veyangoda correspondent writing of this opinion of Dr. Trimen makes the following statement:—"To support the theory of innutrition there is the fact that the severely affected plants are invariably the weakly ones: *per contra* all the weakly plants are not affected." The former statement is an important one, and the conclusions to be drawn from it are in no way affected by the latter. I hold, and I trust I shall make it clear further on, that it is the fact of a tree being insufficiently nourished that brings it under the influence of those agents, the effect of whose work is seen in coconut leaf-disease.

In an article on "salt in coconut cultivation" published in the "Examiner" of February 21st, 1889, the theory put forward by the writer "B" is that trees are possibly suffering from the absence in the soil of salt, or from its presence in too small quantities. This I considered very improbable in an island of the extent of Ceylon, which moreover comes under the influence of monsoon winds. Again there is the fact that a good many trees were affected and badly affected by "coconut leaf-disease" on the sea-border. Quite lately the same writer made the statement that the application of salt to badly attacked trees resulted in no beneficial effect, in fact that it aggravated the attack.

In the "Examiner" of the 22nd February 1889, the Veyangoda correspondent gives the opinion of "perhaps the most intelligent and practical planter engaged in the cultivation of coconuts" to the effect that trees are suffering from an insect attack, that the juices of the trees are weakened and diseased by want of nutrition, and that innutrition is due to the hard and impervious nature of the soil at Veyangoda (where the attack is prevalent in its worst form). This opinion is, in the "Examiner" of March 5th, 1889, said to be that of Mr. William Jardine of Goluva Pokuna estate, Kadirana.

Of the salt theory propounded by "B," Dr. Trimen says:—"I scarcely think that the mal-nutrition of your trees—to which I attribute the dead spots in the leaves—is due to want of salt in the soil; unless indeed the land where they grow is quite abnormally wanting in this almost invariable constituent. . . . I should rather look to the physical properties of the soil, and especially the drainage. That the mortified spots may be set going in the first instance by the punctures of a minute bug is by no means improbable. So far as I have seen, I am not disposed to consider these spots a very alarming phenomenon. They are pretty frequently to be seen on all palms if not in quite a healthy condition, and I quite expect that under a more liberal treatment they will cease to appear.

"W. J." recommended the following treatment to raise the condition of the trees so as to cope with the disease:—"Stiff and clay lands should be broken and turned over in clods to a depth of fully eighteen inches by means of strong steel-bladed picks, afterwards treated with 30 or 40 bushels of freshly slaked coral lime to the acre scattered broad-cast and allowed to be washed in by the rains. The clods would permit of free aeration, and all the rain would be absorbed and percolate through the soil, instead of as at present, more than one-half being lost owing to the impervious condition of the soil." I cannot pass over this recommendation without a word of support. The niggardly treatment which coconut land generally gets, as to the working up of the soil, cannot but tell disadvantageously on the crop. No amount of "trenching" as I have seen it done on some estates will compensate for this neglect. This thorough working up of the soil while it has all the advantages of draining, at the same time facilitates the preparation of plant food. The soil will then be able to draw its moisture both from above and below. The suitability of thorough drainage for coconut cultivation has been questioned.* It is against the principles

of agricultural chemistry that a tree whose roots rest on a water-logged strata should thrive for long. The sickly appearance of trees growing under such conditions is quite a common and familiar sight. It is absurd to point to a solitary apparent exception to this rule and, clinging to it, lose sight of facts founded on laborious scientific research. This mode of argument, characteristic of a warped judgment, is most unsatisfactory to meet. Water may be present to the roots to any extent, but the necessary condition is that it should not be stationary. On the sea-shore we see the roots of the coconut palms continually bathed with water, but the texture of the soil is such as admits of its ready percolation. Thorough draining not only relieves a soil of excess of water, but, paradoxical as it may at first appear, it greatly mitigates the effects of dry weather; when soil is drenched with water, and dried by evaporation, it becomes hard, especially if it be of a clayey nature. Land that is dried by drainage is absorptive and retentive of moisture dropped by dews and acquired from the atmosphere; while the soil deepened by drainage or deep cultivation permits the crop to put forth stronger and healthier roots, and thus becomes secured against drought. The most successful estates I have looked over have received the treatment which secures such results. I observe that within the last year the thorough working up of the soil is being adopted more generally, but the benefits to the tree to be expected in this case will have to be waited for. This mode of treatment must be considered a matter of routine at such intervals as may be thought advisable.

It is no argument to say that because the necessity for such cultivation has apparently not been recognised hitherto therefore it cannot be recognised now. In America once on a time, corn grew and gave large yields year after year with little attention and care, but the time came when this manner of cultivation was no longer admissible, for whatever the crops cultivated, it is plain that continued cropping without proper cultivation and the use of manures must ultimately bring us to a time when the crops grown will no longer pay the cost of cultivation.

As I mentioned in my first report, there is some considerable difficulty in getting at the history of the various plantations, affected and unaffected, but during the time that has elapsed since I wrote, I have been able to gather a good deal of information of this nature, in most cases from those who had a personal knowledge of the facts. I do not intend to mention the names of any estates or even indirectly indicate their situation, for I do not consider it fair (being convinced of the predisposing causes of the disease) to make disclosures regarding the history of any private property in a public report. I am thoroughly satisfied in my own mind that where I have seen the disease in its worst form there was always an antecedent of bad treatment, whether from sheer neglect, from motives of economy, from the use of bad seed-nuts and careless planting; or on the other hand there were natural disadvantages. For while a soil can be made fertile by much mechanical labour and the addition of such substances as it is deficient in, if this cannot be done except at a cost as great as, or greater than, that for which fertile soils can be procured, the soil may be regarded as practically worthless. I have during my observations, seen soils that illustrate all these conditions either singly or in combination.

The circumstance that the mechanical condition of the soil where the trees show the attack, is favourable, is not sufficient for healthy growth. It may occur that though the mechanical condition is not of the best, there may be present in the soil a sufficiency of soluble plant food for a certain period; but on the other hand though the mechanical

of them, more especially as that particular patch had received very generous treatment, he was surprised to find very little root growth, a marked absence of feeding-roots, and most of the roots rotted. This was an opportune bit of experience.

* In the "Examiner" of Sept. 10th, 1889, the Veyangoda correspondent says that having occasion to drain deeply a bit of rich clayey land on which coconuts did not make the growth that one can reasonably expect

condition may be of the most favourable nature, it is quite possible that most of the mineral constituents may be of the most insoluble kind, or of a perfectly useless nature—the necessary mineral ingredients of plant food being absent. Such results depend on the origin and history of a soil—not only on its derivation from particular rocks, but its modification by the natural agents, chemical, mechanical, and animal. If it can be proved that the chemical condition of a soil is faulty, that it lacks or is deficient in one or more of the elements of plant food, while the growth on it is healthy and vigorous, then can it be said that the principles of agricultural chemistry are unsound; while the same conclusion may be reasonably come to, if while both the chemical and mechanical conditions of the soil are favourable, the growth is weakly and unhealthy—of course assuming that the selection and planting of seed nuts were well done.

The existence of isolated areas of unhealthy growth must be accounted for as being caused either by unfavourable mechanical conditions, or by peculiarly congenial mechanical conditions of soil, possibly by an unsatisfactory substratum, or again by carelessness in selection or planting or seed nuts, or lastly by neglect for any period, especially during the early stages of growth. As I have stated before a tree which has up to a certain period appeared healthy and robust may begin to exhibit unhealthy symptoms from a deficiency of plant food, or moisture (possibly induced by a spell of prolonged drought—for water is necessary not only for the assimilation of food, but also for its elaboration and for the circulation of sap). This failure in very limited areas—more limited than in any coconut plantation—is often met with in cereal, root, vegetable and garden cultivation, and special treatment in various ways is necessary where the planting and seed are not at fault; such as improving the mechanical texture of the soil, adding either a material such as lime which liberates plant food, or some manurial substance. In certain cases a previous vegetable growth may account for the exhaustion of particular elements of plant food. It is on consideration of these causes of failure in cultivation that one is impressed with the need for caution in the selection of a property; and where one proprietor has had the opportunity of selecting his own seed-nuts, watching their growth in the nursery, superintending their planting out, helping their start in the field under the most favorable conditions,—for care during the early stages of life whether of the plant or animal is of primary importance for healthy development in after life—it is here that he has the advantage over another proprietor who takes over his estate ready planted. Hence the importance of a careful enquiry into the history of soil and crop to ensure a safe investment, especially in the case of trees of a perennial character. This is too much lost sight of. Often after-care and liberal treatment will improve the condition of trees, and this no doubt may have found by experience, can frequently be successfully done; but as before mentioned there is a limit, and if the effort at improvement entails a cost that is not commensurate with the returns that may be expected, then such a property must be considered a failure. I have in view an extreme case of this nature of an estate most perfectly planted and liberally treated, which every attempt to improve without incurring financial loss, has signally failed.

There have been reports from abroad of coconut trees being affected with disease. In an article by the Hon. B. Howell Jones, which appeared in the "Journal of the Royal Agricultural and Commercial Society of British Guiana," reference is made to the disease affecting coconut trees in Mahacony, thus: "Here and there we saw signs of an inexplicable coconut disease, not to be confounded with the attack of the beetle, and on talking over the matter, both Mr. Smith and Mr. Mustard were of an opinion that it results from the planting of green nuts which grow much more rapidly than ripe ones, and that after bearing one or two crops they seem to get exhausted and die away." Mr. Quelch, curator of the Museum and Editor of the abovementioned Journal, writes me that the disease in British Guiana is evidently identical with that in

Ceylon, and that it is now manifesting itself by a dropping of the half-ripe fruit and branches. I have observed this result in some parts of the Island where the attack is bad. The opinion recorded by the Hon. Howell Jones is worthy of consideration. The growth from an immature nut cannot be expected to be a healthy one; but whether the nut or the soil be at fault, it must be borne in mind that the disease is associated with an unhealthy growth. "The disease," says Mr. Quelch, "is common on the different parts of the Cocos, but it does not seem to spread to any alarming extent."

Mr. J. H. Hart, Superintendent of the Botanical Department, Trinidad, referring to the coconut palm disease in the West Indies and distinguishing it from the attacks of beetles and scaly blight, says that traced to its primary source the disease would appear to be caused by a state of semi-starvation induced either by drought or a deficiency of manurial constituents in the soil of the particular district, and that where these causes do not obtain it disappears. In my own experience I found this to be the fact, for during my visits about the middle of last year I found certain estates suffering from the effects of the prolonged drought which then prevailed and showing much discoloration of leaf, but with the return of the rains and the measures taken to combat the evils arising from a lack of moisture, these effects have ceased to appear. On other estates, however, the disease does not show any signs of improvement, and in such cases I cannot but agree with Mr. Hart that the want of a sufficient supply of plant food is the origin of the evil.

I am indebted to Dr. King, analyst to the City of Edinburgh and the leading Agricultural Chemist in Scotland, for help in the matter of soil analyses for which I had no appliances at the Colombo School of Agriculture. Mr. John Hunter of the Minto House Chemical Laboratory referring to the analysis of a mixed sample of soil and sub-soil from a part where the coconut trees were most affected with disease, says, "You will notice that the soil is very low in phosphoric acid, and low in potash; there is an abnormally high percentage of oxide of iron and alumina. . . . I may say that a soil recently analysed here contained more phosphoric acid than your sample does and yet was incapable of raising a healthy crop." Here I consider we have a flood of light thrown on the subject. The well known maxim of Playfair that "it is the body *in minimo* that rules the crop" instantly suggests itself in this connection. It may be that phosphoric acid and potash are present in the soil, but not in a condition available as plant food, and here it is that the importance of the operations which favour the liberation and distribution of soluble plant food comes in, for a soil may contain an abundance of phosphoric acid, potash and magnesia and yet be infertile if these exist as apatite, feldspar and serpentines. It is needless for me to cumber this report with suggestions as to the best means of supplying phosphoric acid and potash to the soil in a manurial form; let me only remind owners of estates that they should use the most soluble manures containing these foods if they look for early results, and if they wish to come to the aid of their trees before long—as they should. I mention this because I know of cases where manures are being applied in a most insoluble and almost worthless condition.

But on the texture of the soil depends its powers of absorbing and retaining manure. Now the fact that there is an abnormally high percentage of oxide of iron would seem to indicate that more thorough draining and work up of the soil would tend to a better balancing of the proportions of plant food. I am aware that the soils in many parts of Ceylon have very large proportions of iron oxide, as analyses I have before me show, but in the case in point, this preponderance of iron oxide is to be considered together with the abnormally low percentage of the most valuable mineral food ingredients of plants. Certain of the compounds of iron we know are noxious to vegetation, while "reverted phosphate" of iron, as such,

deprives the land of more soluble phosphates which might otherwise be formed.

Here I must support the recommendation quoted in the early part of this report, that lime should be applied to the soil on these infected areas. Not only will lime act mechanically and improve the texture of soil, which being made more porous is better aerated, but it supplies a base which forms soluble salts, and thus liberates plant food. If I remember aright it has been reported in the newspapers that an experiment with a dressing of lime to affected trees did improve their condition.

Where the balance of nature has been disturbed and one crop has been selected for a particular area to the exclusion of all others, contrary to the course of nature, it is but natural to expect that the soil must eventually fail in its supply of certain ingredients of plant food, and this more especially where the soil is not of the most fertile character, when the same food ingredients which the crop most affects are continually being drawn upon. Even were in a state of nature one crop is confined to restricted areas we know that there is such a thing as a natural course of rotation, and one crop gives way to another: this has been recorded in the case of natural forests of trees.

What is of great importance is that the feeding habits of cultivated plants and trees should be thoroughly understood from experience and the results of analysis, and that plants and trees should be so treated by cultivation and manuring as to ensure a sufficient supply of the food ingredients necessary for their healthy growth. Of course there are special circumstances such as the occurrence of long droughts which are practically beyond the control of cultivators, and these have to be dealt with as well as possible so as to mitigate their effects. I have examined some roots dug up from an infected area, which appear to have a tendency to die off, but have not been able to note the presence of any organism which can account for the result. It accounts for the withering tendency of the roots as the result of those causes which bring about the weakened condition of the tree, and specially a lack of sufficient moisture.

The term coconut leaf disease as used in Ceylon I consider incorrect in its application. It has been indiscriminately applied to every form of discoloration on the leaves, of whatever nature. Now there are some discolorations of a withered appearance resulting from the puncture and sucking of minute insects, and these are often seen in healthy trees, the discoloured patches being distinct in outline surrounded by a healthy growth, while the trees are not in any way affected in health. Those however occurring on weakly trees are the nuclei from which decay spreads to such an extent as to seriously injure the health of the trees. Again, there is the appearance of yellow discolorations either as spots or all throughout the leaf resulting from a failure of the leaf to elaborate chlorophyll, and this cannot but be the result of innutrition (where the leaf is not withering in its natural course). In weakly specimens I also found the presence of a fungus presenting to the naked eye a turgid brown discoloration in the leaf tissue, but I am convinced that there is nothing to cause any alarm in the occurrence of the fungus which from its nature need not lead to suspicion of its spreading, or indiscriminately attacking coconut palms.

There have been various means suggested for scaring away insect pests, whether fly, beetle or bug, which it is needless for me to repeat here, but keeping the land clean is of primary importance in bringing about this result. The unsatisfactory condition of the soil as shown by analysis is a matter that must command the attention of those whose minds are exercised about this so-called disease. Sir John Lawes, the greatest living authority on agricultural matters, says, "I consider that plants are liable to be attacked by fungi, parasites &c. in proportion as the soil is deficient in available mineral food . . . The greater the amount of mineral matter at the disposal of the plant, the greater would be its power of resistance."

I consider that there is no cause for alarm about the so-called Coconut Leaf Disease to those who are culti-

vating their lands after the most approved methods. The idea that danger or destruction is threatened generally by a fungoid attack must be put away. The consensus of opinion, and notably that based on analyses of soil, tends to prove that those areas where the disease prevails to such an extent as to disquiet the minds of proprietors and lessees, are suffering from an impoverished condition of the soil so far as the successful growth of coconuts is concerned: and to cope into the disease the soil must be by every available means—which I have endeavoured to indicate—raised to the required standard of fertility.

Member of the Royal Agricultural Society, England.

TEA CROP PROSPECTS IN CEYLON.

HEAVY BEARING OF TEA AT HIGH ELEVATIONS.

NO LIMIT TO PRODUCTION WITH THE TEA-BUSH FLOURISHING FROM KOLLUPITIYA TO THE RANGES ENCIRCLING NUWARA ELIYA.

Our readers will be interested in perusing the following report and opinion by an experienced Visiting Agent not usually regarded as over-sanguine. One lesson that may be inferred is that tea planters in other countries less favourably situated than Ceylon should beware of extending cultivation until they see what the next few years are to do for the crops in this island. Our correspondent writes:—

April 12th.—Prospects so far as *quantity* goes are favourable enough, and people are beginning to realize the fact that it is not only in the lowcountry, and at medium elevations, that heavy yields may be looked for, but even at extreme altitudes, and under conditions which one would have thought a few years ago, were unfavourable to vigorous growth and therefore opposed to great productiveness.

Take for example the higher features of the district of Udapussellawa, which, beside being cold and bleak, are exposed to the influences of a very heavy monsoon wind for several months of the year, and yet the tea on these slopes is exceptionally strong and vigorous, comparing well with some of the finest fields, in apparently more favoured districts. Nor is the yield in any way disappointing; on the contrary, it is surpassing the most sanguine expectations of an expectant public; and I learn on excellent authority that on one estate alone, about 300 acres in extent, upwards of 20,000 lb. of tea was made in the month of March!

Proprietors of lowcountry estates will have to look to their laurels; for the references made to Udapussellawa could be largely multiplied, and I may go further and say that though people generally are beginning to see that high grown tea is capable of producing heavy crops of leaf, there is probably not a man in the island who sufficiently appreciates the productive powers of the soil in such localities as the Agras and Bogawantalawa to enable him to correctly estimate the capabilities of a well-cared-for field of tea, at the seventh year.

'Tis true we have to wait for our returns up-country, we don't get them the second and third years as in the Kelani Valley; but given a good soil, fair jāt, and suitable climate, the yield of a 4,500 feet estate will go on increasing as the bushes advance in age, until full maturity has been reached, and under conditions such as I have named we none of us know when this will be. But these conditions are not exceptional: indeed they apply to a great number of estates—in the Central Province—to say, nothing of large extents of patana which experience has now abun-

dantly proved to be admirably adapted to the successful cultivation of the tea plant.

I frankly own that I see no limit to production of tea in Ceylon, if the bush continues to escape the serious ravages of insect pests and the enterprise is not stifled by causes beyond control. The shrub itself is as tenacious of life as lantana, and flushes over far greater ranges of temperature. It adapts itself to the sunny shores of Kollupitiya and before long will have approached the summit of the mountain ranges which encircle the frosted peak of Pedro.

INSPECTOR.

PLANTING REPORT FROM THE HILLS OF CEYLON.

THE "LITTLE MONSOON" GROWING—A NEW DEPARTURE—A GRAND SHOW OF COFFEE BLOSSOM—CINCHONA THRIVING WELL.

NANTOYA, April 16.

The "little monsoon" seems to be growing. Yesterday, after the usual very hot morning and forenoon, the sky darkened until between 3 and 5 we could scarcely see to read. But beyond a few scatterings the rain fell off until after midnight. This is a new departure, which if continued will be very welcome on estates and on the railway, where the day showers have hindered work. Between 6 and 10 p.m. the rain poured down until 75 cents of an inch was the record of the rain-gauge. This morning is, as usual, calm and watery-looking, promising oppressive heat ending in rain. When the lull before the great monsoon comes the tea ought to run rapidly into flush. There is a grand show of blossom on the Dessford flat of coffee which ought to result in fine crop if the rain does not injure the flowers.

It is surely the very irony of fate that when the bark of *Cinchona ledgeriana* was worth almost its weight in silver all the attention we could pay to the plant, in digging, manuring and terracing the soil, failed to procure satisfactory results; while now that the market is so low that Java plantations are being abandoned, plants the result of seed which came to us by a sort of chance grew well in the nursery and as planted along paths from 5,700 feet altitude downwards are flourishing most luxuriantly. Simultaneously *Cinchona officinalis* growing amongst some of our tea has thriven so wonderfully that in justice to the now more valuable plant we must cut the cinchonas down, storing the bark for that rise in the market which we trust will some day come.

PLANTING IN THE LOWCOUNTRY.

(By a Knight of the Tea Bush.)

April 7th.

The lowcountry has its charms. The cool dusky walk down to muster with the corner of night's mantle over everything, and the coolies half awake moving off slowly to the inevitable plucking. The morning tea in the back verandah looking out on the broken landscape of chena hills and distant jungle—the rays of the now-risen sun illuminating all nature, the crow of the jungle-cock, the sweet whistle of the batagoya, the deep moan of the imperial pigeon, the coo of the fruit pigeon, and the other various notes of birds. As I start for the field and factory the sun is rapidly occupying his throne and making all nature bow before him. By 10 o'clock the erstwhile vigorous planter slowly returns to the bungalow, bowed and weary, covered with honest sweat, thinking only of Pilsener and

shade. The tub gives a moment of coolness and a freshness for breakfast, and then the daily trial of the afternoon commences. Kick off boots, throw off coat, choose a light novel, and lie full length in bed. Deep slumber soon supervenes, and woe betide the man who disturbs the durai now. But hark that fowl has laid an egg and is too proud of it to keep quiet. It is chased and pelted till its shrill cackle dies away in the distance, and master turns over again, and quietness reigns. Sometimes the cock will crow, or the crows will caw, in spite of the anxious servants. About $\frac{3}{4}$ past 2 or 3, a shattered man plunges his fevered face in the cool basin, and has a cup of tea. What a wonderful effect tea has on a sleeping man! Coffee prevents sleep, tea refreshes after sleep. Coffee sustains a man for exertion. Tea refreshes and brightens a man after exertion.

Then I take an hour's walk round by the factory and see the leaf come in, and then perhaps ride over to my neighbour for tennis, or else I have a chair put out in front of the bungalow and enjoy a cheroot and whisky and water.

Men say lowcountry planters drink too much, I fear they do; but the question is, what is too much? I take 3 bottles of Pilsener and 2 or 3 whiskies and water a day. If I see men I take a whisky or two more. [Oh! too much altogether. —P. D.]

There is no doubt one requires a good deal of liquor in the lowcountry if one is over thirty. Youngsters under thirty will suffer if they exceed.

The evenings are very sweet; beautiful sunsets every night; and the air is pleasant, balmy, as the fierce sun is disappearing in the waves of the Indian Ocean. White drill and a huge pith topee is the proper dress.

The cooly strike a new comer from the hills as being very black;—whereas a lowcountry man fancies he sees a red tinge in the coolies' cheeks when he goes up to Dimbula. Such a tinge is visible to a close observer. Have none of your readers seen a cooly blush? A sort of maroon tinge on the cheeks. Then the gait of the up cooly is refreshing to a lowcountry man. The swinging stride and free energy is the result of fine bracing air and wholesome water.

TEA IN AUSTRALIA.

(From Rowbotham & Co.'s Monthly Tea Market Report.)

SYDNEY, March 25th, 1890.

There is only a small business to notice during the past four weeks, either privately or at auction, and the transactions put through have been principally confined to late arrivals, which have shown such excellent value. A small catalogue of these Teas was printed for the 5th instant—about 2,000 packages—Flavory Panyongs selling from 5d. to 7d. There has been no inquiry at all for finer first crop kinds, but it is expected that this will shortly be experienced. "Price" Tea in light weights maintains its position, but there is really hardly any demand for it, the quantity of better class teas available at an advance of $\frac{1}{4}$ d. to $\frac{1}{2}$ d. per lb. putting it quite out of the market. S. O. Pekoes are entirely neglected, and are fast becoming a dead letter in the trade, their place being taken by Indians and Ceylons and *Hang Mee*. This latter article is now being used by all the principal blenders, and the importation of it should be well worth the attention of some European house, the trade so far being in the hands of the Chinese.

Shipments both from Foochow and Calcutta may now be regarded as closed, so that the statistical position and consequent prospects for the remainder of the season can be reviewed.

Our own Imports are nearly 3 million pounds more than last year, the increase being almost entirely in Indians and Ceylons. Our bonded stock is also half a million pounds more than it was at this time last year, and then, although the arrival of the first steamer was delayed until the 11th August, we still had "more than enough."

The Melbourne bonded stock is said to be nearly a million pounds less than last year, but even this reduction is not sufficient to place that market in a healthy position—for, notwithstanding the late arrival of the New Teas in 1889, the stocks were even then far in excess of any previous year. It must also be borne in mind that, owing to the extra stock held here, we shall not draw on Melbourne to the same extent that we did last year between March and August.

We do not expect, therefore to find Melbourne with a stock much under 3,000,000 lb. (which is a million too much) by the 1st August next, and Sydney will have about 1,250,000 lb., which is half a million too much.

With these figures before them it is most earnestly to be hoped that intending Importers will, in their own interests, be moderate in their orders for the coming season, and that they will also be unanimous in their instructions to al low no shipments to take place from Foochow, on their own accounts, until at least as late as was the case last year. If the Foochow Houses object to this, and some of them decide to load the steamers on their own account and get them away early, the result (if the Teas are no better value than they were last season) will be the most disastrous to the shippers ever yet experienced. The consequence will be a fall in Foochow when operations may be undertaken with advantage.

ARRIVALS.—S. S. "Sikh," from Foochow, 552 packages; Coasters from Melbourne, 7,963 packages. Total, 8,515 packages.

INDIA AND CEYLON.

ARRIVALS.—S. S. "Nerbudda," from Calcutta, 289 packages; S. S. "Oceana," from Colombo 314 packages; S. S. "Doruuda," from Calcutta, 169 packages; S. S. "Clitus," from Calcutta, 324 packages. Total, 1,096 packages.

There have been no public sales of these Teas, but privately they have lately had more attention than Chinas. The demand is increasing extensively, and the small shipments that come to hand are readily placed. The "Clitus" shipment was sold to arrive a satisfactory prices.

The season in Calcutta is practically closed, and no further shipments of any consequence can be looked for until July.

VESSELS ADVISED.—S. S. "Taiyuan," from Hongkong sailed March 3rd.

Imports, Customs Returns from 1st July 1889, to 14th March 1890 7,003,439 lb.

Imports, Customs Returns from 1st July 1888 to 15th March 1889 6,304,160 lb.

Exports, Customs Returns from 1st July 1889 to 14th March 1890 379,800 lb.

Home Consumption, Customs Returns 1st July 1889 to 14th March 1890 4,403,530 lb.

Stocks in Bond, Customs Returns 14th March 1890 2,167,420 lb.

Stocks in Bond, Customs Returns 15th March 1890 2,623,690 lb.

Arrivals from Melbourne, from 1st July 1889 to 14th March 1890 922,570 lb.

Arrivals from Melbourne, from 1st July 1888 to 15th March 1889 1,133,920 lb.

Shipments from China to Colonies, season 1889-90 to date 21,500,000 lb.

Shipments from China to Colonies, season 1888-9 to date 21,125,000 lb.

Shipments from China to Colonies, season 1887-8 to date 21,370,000 lb.

Exchange—Foochow on London, 6 months sight, 3/2.

Freights—Foochow to Sydney, £1 10s.

COCONUT TREES AND CATERPILLAR BLIGHT.

(From a Coconut Planter.)

Have you noticed the condition of the coconut trees fringing the shore of the lake near the Slave Island Railway Station and the Ice Manufactory?

They are suffering from a bad attack of the caterpillar blight, and look as if they had been badly scorched. In fact when I saw them last evening my first idea was that some of the native huts in this neighbourhood had been recently burnt down! The caterpillar plague is one of the greatest pests on coconut plantations in the Batticaloa district, but I have never heard of it attacking trees in any other parts of the island, and this is the first time I have noticed it outside the Eastern Province.

Though not as a rule proving fatal to the tree it retards and sometimes altogether stops its bearing powers for a year or two after its first appearance.

Coconut planters in the Western Province and especially in the neighbourhood of Colombo will have to beware.

[How to check it, can our correspondent say? —Ed. T. A.]

TEA SEED AT WEYMOUTH IN DORSET.

About 18 months ago I sent a box of Ceylon tea seed to Mr. Wm. J. Skene of Weymouth who now writes to me:—"It may interest you to know that some of the seed you sent me home I planted in our garden in the open, just about 12 months ago and although we have had pretty severe pests and any amount of very cold east winds, the plants seem strong and healthy, but of course have not grown much since the winter began and have had no flush to speak of. I have some also in pots in the greenhouse (a cold one), but those outside look quite as well if not better. I gave away a lot of the seed, and everyone tells me it is growing well, but I fear labour is too expensive for us to compete with Ceylon, so you need not be afraid of our doing you any harm." Tea is undoubtedly a very ubiquitous plant.

—Planter.

THE CURRENT CROP OF CINCHONA BARK.

Our local contemporary published the following paragraph the other day:—

"In computing our annual estimates of produce we put down Uva as likely to despatch 2,200,000 lb. of cinchona bark this year. We divided this quantity as follows:—

Badul'a	1,000,000 lb.
Haputale	820,000 lb.
Madulsima	400,000 lb.

Total...2,200,000 lb.

"A gentleman well conversant with all the Uva districts, but more particularly with Badulla and Madulsima, informs us that his estimate for the output of these two districts this year is 2,150,000 lb., compiled from estate returns in most cases. This amount is more than we anticipated, being almost as much as we had put down for the whole of Uva, but, as our informant has only just completed his estimates and ours were made out in Jan. last, it is quite possible he may be more right than we. This would add some 700,000 odd lb. to our total estimate for the year, and bring it up to 7,250,000 lb.; and as we have already put 2,187,242 lb. on board ship to end of March, it is quite likely that that quantity will eventually be shipped."

We need only remind our home readers that our estimate for the year has been 7 million lb. Up to the 17th April, the total exports of bark are 2,288,184 lb.

Against for same period 1889 .. 2,993,960 "

Short 705,776 "

The total export for last year was 9,283,729 lb.—so that the present deficiency would point to an even lower export in 1890 than 7 million lb.

EXPORTS OF INDIAN TEA.

Indian Tea Association, Calcutta, April 14th.
 DEAR SIR.—The General Committee have the pleasure to hand you their Monthly Return of shipments of tea from Calcutta ;—

EXPORTS OF INDIAN TEA FROM CALCUTTA.

	1890	1889	1888
	lb.	lb.	lb.
Exports to Great Britain in March	2,782,942	1,010,703	571,850
Exports to Great Britain from 1st May to 31st March	97,746,652	92,270,813	83,155,086
Exports to Australia and New Zealand in March ...	30	1,931	56,333
Exports to Australia and New Zealand from 1st May to 31st March ...	3,382,041	2,858,499	2,407,979
Exports to America in March	10	13,634	450
Exports to America from 1st May to 31st March ...	164,707	169,418	48,145
Exports to other places in March	71,937	213,303	435,928
Exports to other places from 1st May to 31st March	1,463,971	1,068,231	1,088,666
Total Exports from 1st May to 31st March ...	102,757,371	96,367,041	86,699,876

—Yours faithfully S. E. J. CLARKE, Secretary.

FAILURES AT FOOCHOW: THE TEA GUILD.

(From the Foochow Echo.)

Quite a number of piece goods shops, we learn, have failed since the beginning of China New Year and their liabilities are computed at \$200,000. Owing to the inability of the native banks to grant the usual advances, it is feared many more failures will yet be recorded. The great falling off in the tea trade of last season has greatly affected all other trades of the port, which are entirely dependent on tea.

It is with great satisfaction indeed that we learn, that the so-called Tea Guild at this port is shaky, and many of its members are proposing to dissolve the association. We sincerely and earnestly hope that the report is true, as we consider this association, which was unwisely recognised by foreign merchants only a few years ago, has caused more harm to the trade than good, and no doubt the members themselves have found at last that it is so. We are indeed at a loss to understand why the interests of tea growers and buyers should be entirely placed at the mercy of this Society dictating rules and regulations which a few of its wealthy members only derive any benefit from. Let us hope however that as soon as its principal members return from Canton,—in whose absence we understand, no change can be effected,—the intended dissolution will be an accomplished fact, which will undoubtedly do a great deal of good to the trade.

QUININE AND ANTIPYRINE.

(From C. F. Boehringer & Söhne's Report.)

WALDHOF NEAR MANNHEIM, April 1st, 1890.

QUININE.—The statistical position of Cinchona Bark is constantly improving. Not only do the exports from Ceylon, and the arrivals by rail in Colombo, show a large diminution, but also the import and stocks in London have undergone a considerable decrease. The growth of Java exports on the other hand, is but small, and remains far below the truths of the prophets.

EXPORTS FROM JAVA.

1st July 1889 to 15th March 1890 about	3,520,000	Amsterdam	lb.
Do 1889 to 31st do 1889 do	3,276,574		lb.
Do 1887 to do do 1888 do	2,693,088		lb.
Do 1886 to do do 1887 do	1,733,153		lb.
Do 1885 to do do 1886 do	1,153,124		lb.

Business in quinine during the past month bore the same character as in February. Speculative purchases were reduced to a minimum, while the inquiry for actual consumption was continuous and strong.

The increase in the consumption of quinine in Central Europe, especially Germany is worthy of note. In no other country has the enthusiasm for the recently discovered antipyretics been so exuberant. Indeed some German physicians have entertained exaggerated opinions concerning the value of the new remedies, whereas experience teaches that they are not altogether so harmless and reliable as supposed. Quinine that in our country had been somewhat neglected, has lately begun to recover that position to which the experience of half a century entitles it.

Dr. E. Falk of Berlin has commenced the publication of a series of articles summing up the observations of European and American physicians concerning the effects of the new remedies, and to which we may have occasion to refer later on. His first article deals with

ANTI-PYRINE.—Among the ascertained consequences, partly disagreeable, partly even dangerous of this antipyretic, the following are given: 1 Vomiting; 2 Pressure or burning pain in the stomach; 3 Bleeding (after prolonged use); 4 Discolouration of the teeth; 5 Singing in the ears; 6 Amaurose; 7 Epilepsy; 8 (In 10 per cent of cases) Eruption of the skin (Exanthema) accompanied not unfrequently by most painful itching, irritation and fainting. 9 Tumours, 10 Violent sneezing and watering of the eyes. By seven authors an absolutely contradictory effect of Antipyrine is determined to obtain, the temperature of the body, instead of falling, rising rapidly accompanied by shivering, and to some extent by dangerous symptoms. Subcutaneous injection of antipyrine always attended by great pain, is sometimes followed by violent inflammation, formation of abscess, and even gangrene.

QUININE AND ANTI-PYRINE.—Some remarks on these products by Messrs. Böhringer & Sons of Mannheim, given above, well deserve attention. They consider the statistical position of cinchona bark to be constantly improving.

CEYLON TEA IN AMERICA.—In the *Tropical Agriculturist* (Ceylon) for January we find a letter from A. Melville White, dated from Philadelphia, in which he discusses the efforts being made to introduce Ceylon tea in this country. The American is fond of coffee; the German-American of beer; the Irish-American of whiskey; but nobody of account takes to Ceylon tea, disliking its body and flavor.—*American Grocer*. [We shall see how long it will be before the *American Grocer* alters its tone; the *English Grocer* did not think much of Ceylon tea at one time.—Ed. T. A.]

CHINA TEA is in such a bad way, says the *Indian Agriculturist*—that the time cannot be far off when either it will cease to be of account in the nation's foreign commerce, or the Chinese Government will be compelled to lower the transit and export duties on the staple. These duties amount to about 40 per cent on the value of the tea, and no doubt they are a welcome contribution to the imperial revenues, seeing that the annual export of tea exceeds 200,000,000 lbs. But the producers, who have more forethought than the collectors of revenue, note that in three years the export has declined from 290 millions to 214 millions, and they tremble for the future, especially when they observe that the exports of tea from India and other countries have risen in the same three years from 80 million lbs. to 160 millions. The significance of these figures is unmistakable, and it came home very practically to the China exporters last year when tea which they sent to London at a cost of 1s per lb. had to compete there with other teas of the same quality at 6d. In consequence of this damage to the trade the business of growing and drying tea is being neglected in the land of Chang, and many old planters are said to find a more lucrative employment in the cultivation of the bamboo.

SISSAL HEMP.—Mr. Paterson of Padalur, S. E. Wynaad, inquired whether the Agri-Horticultural Society of India, had any plants of the Sissal hemp for sale, and the price per mille, as he was desirous of procuring about 50,000 plants. He was informed that the authorities of Kew have been addressed on the feasibility and cost of importing sufficient plants to set up a trial plantation.

COCONUT LEAF DISEASE.—We call attention to the very sensible Supplementary Report furnished by Mr. Driberg, Superintendent of the Agricultural School, on the subject of the alleged coconut leaf disease. Mr. Driberg deserves the thanks of all coconut proprietors for so carefully and discriminatingly setting about the elucidation of the question entrusted to him. His very practical, judicious remarks on the cause of the leaf discoloration and on the poor appearance of trees planted on unsuitable soil—or soil not worked by lime into a satisfactory condition—will be generally approved of; and it is not too much to expect that both the scientist—Dr. Trimen for instance—and the practical planter will cordially endorse Mr. Driberg's findings, conclusions and recommendations. Dr. Trimen had previously relieved the public from any dread of a repetition of a widespread fungoid disease; but Mr. Driberg's Supplementary Report is no less timely, reassuring and useful.

IMPROVEMENT IN TEA CULTIVATION.—At the Annual General Meeting of members of the Indian Tea Association held on the 7th April, in the rooms of the Bengal Chamber of Commerce, Mr. J. N. Stuart (in the Chair) said in the course of a long speech:—

“A suggestion has come from Assam that the Secretary of the General Committee should from time to time visit the various tea districts for the purpose of conferring with local Committees, and obtaining the views of planters on various points; if a suitable man could be got, who might be a planter of standing, and who would inspire their confidence, the arrangement would probably do more good to the planting interest than anything else: the opportunity for adopting the suggestion seems a suitable one. Reference is made in the report to the efforts put forward in London for pushing the consumption of Indian tea in France or America; if the work begun at the Paris Exhibition is strongly supported now, the money spent will have been well laid out, otherwise it will be so much wasted. The Association has done what it could by guaranteeing a sum of £500 towards the Exhibition. This sum was nearly all subscribed by the agency houses, who moreover had most of them, already subscribed to the guarantee fund in London. There is now an opportunity for the many proprietors of private gardens or shareholders of Companies who have not subscribed to assist in developing the consumption of India tea in France. The General Committee, believing that improvements might be made in the system of cultivation, manuring &c., of tea, have associated themselves with the Agricultural and Horticultural Society in a scheme for analysing and reporting on the various soils, and the manures suitable for tea, and have guaranteed R10,000 for expenses. This expenditure will be spread over two or three years, and it is hoped that valuable information will be gained by the employment of an expert to be appointed, and that we shall have more reliable data than we at present possess regarding the soil, manure, and method of cultivation best adapted to the tea plant. I venture to think that a few years hence we shall look back with astonishment to the unscientific and happy-go-lucky manner in which we have carried on the cultivation and manufacture of tea, and I trust you will give your approval to the action of the Committee in attempting to place the industry on a more scientific and, we trust, sounder footing. In view of the expenditure to be incurred, the Committee propose to make the subscription as it was originally fixed, one anna per acre instead of 9 pie; the small increase will be grudged by no one, if the efficiency of the Association is, as we hope, to be increased.”

GUM ACACIA.—The Mysore Province produces large quantities of gum acacia commonly called gum arabic. The largest quantities come from Maddur and Chennapatam on the Mysore line, and from Gubbi on the Harihar Branch of the Southern Maharashtra Railway. Three qualities are sold in the local markets. Tears of gum, almost transparent, fetch the highest price. Pieces slightly discoloured are passed second, while an admixture of bark lowers the value to a third place. Now is the season for the gum harvest, and brokers from Madras houses are busily buying in all they can get. The prices vary from 1-8-0 to 2-4-0 per maund of 25 lb., while in the London Market as much as 50 shillings per cwt. are received for the same gum.—*Bangalore Spectator.*

THE RECENT FALL IN BARK.—is thus explained by the well-known London Brokers Messrs. C., M & C. Woodhouse in their report of March 20th:—

A large proportion of the Bark offered at auction during February consisted of Wynaad and other South East India, which being as a rule bright and well prepared, met with a good demand at full rates. The value of the unit was maintained about 1½d to 2d until the last Public Sales held on 11th inst., when the tone was decidedly flat and about one-third of the Ceylon and East India offered was withdrawn, the unit being quoted 1½d to 1¾d. This depression has been attributed to large Public Sales of Java Bark advertised for the 27th inst. in Holland, at which over 5,000 packages will be offered, estimated to contain nearly 600,000 oz. of quinine. This is no doubt a large amount, but if the flatness in the market is due to this cause it is a question if it is not being overdone—we should rather consider it in a great measure owing to some weak holders of quinine on the spot who are pressing their quinine on the market at declining rates, although the German manufacturers are holding back and will not offer below 1s 4½d per oz. for best marks. At the close there are sellers of second-hand quinine at 1s 1½d per oz. on the spot and a few sales have been made as low as 1s 1½d per oz.

TEA PROSPECTS IN ASSAM.—My forecast of an early season in my last has not come to pass, and at present it seems as if it will be a rather unusually late one. Little over half an inch of rain has fallen during the month, and we are some three inches short to the corresponding date last year. The drought would not have mattered much, but hardly a day has passed without very high dry winds which have materially checked the growth of the bushes, and I regret to say “red spider” is slowly but steadily making its appearance on most gardens. A few good heavy showers would soon see us in full swing, and, though badly wanted, I doubt if we shall have much heavy rain till after the moon has passed the full, although latter day meteorologists and scientists would have us believe there is no connection between the phases of the moon and rainfall. The earthquake on the night of the 8th or morning of the 9th instant reported by several of your correspondents from different districts was felt here also, and the shock was an unusually severe one. My Babu told me in the morning it lasted 10 minutes, but I think a similar number of seconds would be nearer the mark. His house is rather a rickety one. Local coolies, at any rate as far as Central and Lower Assam are concerned, are very short this year, and once more we are realising the unreliability of Kachari labour. I hear there is a good deal of competition going on for those available and looking out for work, and I suppose a lowering of rates or advance in rates will be the inevitable result. Should my surmise prove correct, a pity in these hard times for tea. At last the roads have been thoroughly taken in hand, and on parts of the Trunk Road I see very heavy work, raising the bund several feet. I only hope they will get it done before heavy rain falls, or travelling in parts will be impracticable. I hear that from 1st proximo all local works are to be directly under the control of the Deputy Commissioner, a change which should be an advantage.—*Cor., Calcutta Englishman.*

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE,

COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for May:—

INDIGENOUS FOOD PRODUCTS: CULTIVATED AND WILD.—VII.

By W. A. DE SILVA.

Celastraceae.

14. *Salacia Reticulata* Wight—Sin: Himbutoo.

This is an arboraceous creeper growing wild in the warm parts of the island. The slender stems which bend to form an arch and the dark green reticulated tough leaves are very marked. The fruits which are round in form are produced in large numbers; they are generally about an inch in diameter. The outer covering of the fruit is very smooth, and when young is of a dark green colour, but when ripening turns first into a slightly yellow colour, and when fully ripe to a reddish yellow. The fruits contain one and sometimes two large globular seeds, and around the seed and beneath the epicarp is found a soft fleshy substance, which, when ripe, is of a sweet taste, but in a raw state this substance is not fleshy but hard and astringent. The pulp found along with the seed is eaten. The woody stem of this plant is used by Native Medical Practitioners in cases of diabetes.

Ampelideae.

15. *Vitis Quadrangularis*. Wall. (*Cissus Edulis* Dalz). Sin: Hiresa.

This is a creeping plant commonly met with in the warmer parts of the Island. The stem is quadrangular and formed of as it were separate links or pieces from 5 to 6 inches in length, the joint between two such pieces is the node, and the stem is very green and succulent when in the young state; the leaves are simple dark green, and formed of three curves. There are tendrils by which the plant creeps and lays hold of others. The juice of the stem contains acid substances as well as slightly acrid Principles; the latter are not very marked.

The young stem is used in curries. It is cut into small pieces and split, when the pieces are first immersed in hot water to remove the acidity. After this process is gone through, they are cooked as usual, when they form a good curry. This plant is also in high repute as a medicinal one. The juice of the stems is used in the preparation of a medicinal oil, and is considered to be a specific in earache. It is also used externally in eye diseases and internally for piles and affections of the stomach. It also acts as a mild purgative, evidently owing to the presence of acids, and is successfully used as such by Native Medical Practitioners.

16. *Leea Sambucina* Willd: (*L. Staphylea*). Sin: Burulla.

This is a shrubby plant met with in the warmer parts of the island. The stem is characterised by its soft green appearance when young, and the black colour which it assumes when mature. The nodes are regularly set, and the stem contains a good deal of pith. Another feature of this plant is the readiness with which it gives out adventitious roots from the nodes. The leaves are compound (pinnate), and the leaflets are large and well-shaped with a terminating apex. The young leaf buds are of a pink colour and tree, while the full-grown leaves are dark green and well marked with the veins. The fruits appear in clusters and are green and hard, when raw, but when ripe they are succulent and assume a jet black colour. The succulent fruits are acrid and are slightly poisonous. The portion which is used for eating in this plant is the young leaf bud. These young buds are generally cut into thin shreds and made into a dry curry with coconut, chillies, &c. The very same leaves are used in lieu of hemp leaves and become slightly narcotic when allowed to ferment.

The *Leea* leaves are used by Native Medical Practitioners to expel worms in children, and also to our

ringworms and other cutaneous diseases and sores caused by burns. Its fruit is used in curing warts.

Olacineae.

17. *Otax Zeylanica*, L. Sin: Mella,

Is a small tree found growing in the lowcountry of Ceylon. The leaves are alternate and attached to the stem by short stalks. They are of ovate shape with entire margins, and the midribs are prominent owing to the slightly pink colour they bear. The leaves emit a peculiar foetid smell when bruised, and taste astringent. The fruit is a small drupe containing one seed.

The leaves are used for curries in different ways. One form is a dry curry, made into small shreds and cooked with coconut &c. They are also used fried in oil. For this purpose both fresh and dried leaves are employed. The curry is considered to have properties of curing windy complaints, &c. but is heating. It is said that the foetid wood of this plant is employed in malarial fevers.

CEYLON BEE CULTURE. IV.

By ABA.

The three classes of individuals which constitute a prosperous colony were illustrated in my former article, and a brief description of the queen and drones was also given. We now come to the workers who are the most important of the three classes.

The working bees, well-known I have no doubt to most of my readers, are imperfectly-formed females. Each worker is provided with a sac for carrying her supply of honey home. The wax from which the combs are built is supposed to be secreted under the scales of the body from the honey the insects eat.

The following is taken from Chambers's Encyclopædia:—"The combs of a bee-hive are parallel to each other, forming vertical strata of about an inch in thickness, and distant about half an inch from each other. The cells are therefore nearly horizontal, having a slight and somewhat variable dip towards the centre of each comb. The central comb is generally first begun, and next after it those next to it on each side. Circumstances frequently cause some departure from this uniform and symmetrical plan, which however still remains obvious. Each comb consists of two sets of cells, one on each side; and it may be mentioned as an illustration of the wonderful industry of bees, and the results of their combined labours that a piece of comb 14 in-long by 7 in wide, and containing about 4,000 cells has been frequently constructed in 24 hours. The greater part of the comb usually consists of the kind of cells fitted for breeding workers, a smaller part of it of the larger or drone cells. After the principal breeding season is over, the cells of some parts of the comb are often elongated for the reception of honey; and sometimes combs of greater thickness, or with un-

usually long cells is constructed for that purpose alone, in which case the mouths of the cells are inclined upwards, more than is usual with the ordinary brood cells. When a cell has been completely filled with honey, the mouth is sealed or covered with wax."

Wax is not the only material out of which combs are made. Another substance called *Propolis* or bee-glué is gathered by the bees from the trunks of trees, and is used for a great many purposes, such as stopping up crevices in the hive, for strengthening the cells, varnishing the inner surfaces, &c.

Bees are not without their enemies. Among these are certain species of moths, which enter the hives and deposit their eggs; when these eggs are hatched the larvæ feed upon the combs, &c.

(To be continued.)

THE CULTIVATION OF BARLEY IN CEYLON.

By W. A. DE SILVA.

The cereal barley (*Hordeum*) is one of the most extensively cultivated grains. It was known and cultivated from times far remote as evidenced by historical records of antiquity.

The original home of this grain is supposed to be Central Asia, where a suitable climate prevails for its successful culture; it gradually spread into Europe and India, and is at present cultivated to a large extent in such places where the soil is suited, as in Belgium, Holland, Prussia, Northern India, &c. Being a plant which is most productive where the climate is moderately dry and warm, it does not thrive in places where an excessive hot climate prevails, neither does it do well in very cool climates. In former times this grain was used widely as a food, but now it is mostly used in the preparation of beer.

The cultivation of barley must suit such parts of our island as are possessed of a mild climate: Some time ago its cultivation was tried in Uva and Nuwara Eliya districts with good results, but since nothing more is heard, whether it is still carried on, or it proved a failure by some unforeseen cause is not known. At any rate it would be interesting to know further particulars of its culture with a view to understand what improvement in the methods followed is required in order to obtain better results.

The results of its cultivation in Nuwara Eliya in 1886 is reported in the *T. A.*, taken from the Assistant Government Agent's Administration Report as follows:—"The Ratamahatmaya (of Hewaheta) grew it on some land at Hanguranketa and obtained 100 bushels, the seeds yielding about 12-fold."

A yield of 12-fold is not a bad one, as a bushel is worth from R2 to R3. But if the acreage of land in which the cultivation was done, and such other particulars as to the mode of growth and nature of soil &c. were given, it would have been more interesting, as serving as a guide for others to follow. The subsequent

TROPICAL AGRICULTURE IN PERAK:
RICE—PEPPER—COFFEE—TEA.

The prospects of the present rice crop are very hopeful, and there are a good many more fields under cultivation than usual, a number that have been lying fallow for years having been planted up.

The natives are beginning to realize the advantages the district affords for the cultivation of pepper, and applications for land under the Special Regulations are now almost daily received. During the year 196 acres have been allotted, though, owing to unavoidable delay in the demarcation, agreements have only been issued for a few blocks. It is to be regretted that the Perak Malays understand so little about pepper planting though they will have opportunities of learning something of it from the Banjer and Menangkabau Malays, who are now coming into the district with the intention of opening up pepper land. Mr. Cook's plantation at Gunong Pondok and Syed Musa's at Pasir Panjang have both been very successful so far, and the sudden rush for pepper land is no doubt attributable to this. As yet the majority of natives have a very vague idea as to the cost of opening up a pepper plantation, and I have several times received applications for a hundred acres from people who have not command of sufficient labour or capital to open up two.

Messrs. Huttenbach and Thompson Low examined the land along the northern side of the Taiping-Kuala Kangsa road with a view to selecting 2,500 acres as part of Mr. Huttenbach's agricultural concession. They pronounced the soil to be superior to any they had seen in other parts of Perak.

Coffee planting also bids fair to prove a success. The estate at Kamuning is doing well, and Mr. Thomas Fraser, manager of the Waterloo Estate, whose long experience of coffee planting in Ceylon and several years' experience in Perak, enable him to offer a valuable opinion, writes as follows:—

"The cultivation of coffee promises well, and, where land is judiciously selected and opened, it cannot fail, in my opinion, to be a success, with such liberal terms, as the Government is now offering to the public to take up and cultivate land with coffee Arabica. There should, when these terms are better known, be a very considerable demand for land."

Mr. Fraser has kindly furnished me with the following statement of the acreage of Waterloo estate now under cultivation:—

Old coffee	70 acres.
Young coffee, one to two years old	53 "
Do planted this season	103 "
TOTAL IN COFFEE	226 "
Grass planted this season	6 "
Land being opened for coffee	68 "

To be in cultivation this year ... 300

The experiment at the Hermitage estate of leasing at a nominal rent, seven acres of tea trees to four Chinamen, for a year, resulted satisfactorily. Three qualities of tea were produced. The first, styled Lun Fong Cha, was valued by the Superintendent of Plantations at 10d per lb.; the second, Pak Cha, at 9d or 10d, and the third, Nua Chum Cha, was reported to be of better quality than that sold locally at 25 cents for less than an ounce.

The "Cicely" tea estate is also to be leased to some Chinese, but there had been delay in preparing the title deeds, and they have not yet taken the estate over. There is, however, nothing to prevent them doing so now, as their objection to the duty clause, which was the reason of the delay, has now been withdrawn.

During the year 2,932 titles for agricultural lots were issued, the total acreage of land alienated being 3775 acres.—*Perak Government Gazette.*

SEEDLING SUGAR-CANE.—The last number of *Garden's Field, and Forest* (Demerara), contains an interesting account of six seedling varieties raised at the Dold's Botanical Station, Barbados. These were selected from a lot of natural self-sown seedlings, discovered in Barbados some two years since. They are spoken of as very promising. The seeds take about seven days to germinate.—*Gardeners' Chronicle.*

COCONUT PRODUCTS.

One hears and reads a good deal about the "pushing" of Ceylon Tea, but very little, if anything, about a similar operation in connection with Coconuts. A stir was made a few years ago about "pushing" Cinnamon; and the simple and obvious means to the end was, after much controversy, adopted of holding more frequent sales. The idea was that the frequency of auctions in London—the world's great emporium of commerce still, in spite of competition without and dissension within—would serve as an advertisement of the spice, and popularise it as a flavouring substance of undoubted wholesomeness. One should have thought that no one had any right to interfere with a Proprietor's choice of times and seasons for the sale of his produce. It turned out to be otherwise. The greatest opposition was manifested by the magnates of Mincing Lane to any departure from quarterly sales. The interests of buyers and sellers are not precisely identical—the one trying to pay the least he could, and the other to get the most he could. The producers at first exhibited firmness enough to tell the buyers that if they did not care to buy at the monthly sales, they might stay away; but the spice would be offered thrice a quarter. A combination to prevent bidding altogether by a few leading Brokers in the Lane failed, but the combination was strong enough to prevent any appreciable rise in prices at the sales. That a continuation in the policy of more frequent sales would have led to the results aimed at is, of course, only a surmise; but all reason pointed to the probability of success. But in a short time the producers of Cinnamon yielded to the pressure brought to bear on them the more confident few being unwilling to risk the boycotting of their produce in presence of the tendency to yield of the vacillating many. So, the idea of more frequent sales was knocked on the head, and Cinnamon has reverted to the comfortable antediluvian practice of quarterly sales, while other produce, including every spice in creation save that which has given its name to the Spicy Island, is sold once a week! It is not to be expected from people who yielded in so small a matter, that they would be able to carry out a more ambitious project, such as the engagement of a travelling Agent to bring the producer and the consumer nearer each other, and thus save to both, in reasonable proportions, the profits of middlemen, Cinnamon continues, as a consequence, to fetch disappointing prices.

We are not aware whether even so feeble an attempt as the foregoing has ever been made to push the sale of the products of the Coconut palm. If there has been any project, it neither originated with, nor was worked by, the producer. The Merchant—the local buyer of the raw products—may have done what in him lay, either alone or by combination, to make the Oil, the Nuts and the Fibre better known, and to open markets for them; but the Planter has been content to grow the product and get what he could for it on the spot. The difference between the two industries, which has led to such widely different proceedings, is that Tea planting is mainly in the hands of Europeans, and Coconut planting in the hands of Ceylonese. The former bring to bear on their work, not only a larger share of inherited energy and enterprise, but a more intimate acquaintance with the commercial methods which have earned for Englishmen the distinguishing appellation of "the nation of shopkeepers." One, and perhaps the main, explanation of the backwardness of the Ceylonese in this respect, is the system of education which has obtained here from the date of the British occupation, if not from before. The system has made the energies of the people run in particular grooves, and has rendered departure from them distasteful, if not impossible. There is nothing easier than for "reformers" to declaim on the backwardness of the Ceylonese in trade, commerce, manufactures and industrial pursuits. It occurs to few to find the explanation of it in the faulty system of education, and to seek to promote measures for industrial and technical teaching. The beginning of the remedy is to be found there, just as the remedy for destitution and disease among

villagers is a pure and abundant supply of water, and for short Paddy crops irrigation and improved methods of cultivation. While saying this much, and ready to do all in our power to give a more practical direction to education, we do not indulge in the hope that the millenium will dawn when a few Technical Schools have been established. Overcrowding is as much a complaint in the arts and manufactures as in the professions; and even in England, with its immense industrial and manufacturing resources, the rush for place both Government and private, chiefly Clerkships, is perhaps keener than ever. That it with altogether subside here is chimerical.

Nor must it be supposed that there are no Ceylonese who have not risen to their opportunities, and even gone in advance of them. Moratuwa men have become synonymous with skill in handicraft and enterprise in trade; and far off, neglected Jaffna still maintains its pre-eminence for devotion to agricultural pursuits in the face of overwhelming obstacles. The wealthy De Soysas, Pierises, Rajapakses, Silvas and Fernandos of the Western Province are but types of their less opulent countrymen who, as Traders, Merchants, Arrack Renters, Mine-owners, Building Contractors, Coconut Planters, Coffee Planters, Tea Planters, and Cinnamon Planters, have availed themselves of opportunities as they presented themselves, outside the professions and the Government services. Many public writers lose sight of the fact that prominent success in the professions and in office, such as has been attained by Ceylonese in the face of keen and continued competition, demands qualities at least as high, though of a different character, as those which secure success in the walks of agriculture and commerce. Another point that is forgotten is that the majority of those who have wealth or earn a competence, do invest in land and improve them. If they are the drones that they are represented to be, who are the Proprietors of the broad acres which annually add to the cultivated area of the Northern and North-Western Provinces? It will be found on enquiry that they are professional men, brokers, Government servants and others who are equally contemptuously spoken of. We advert to these facts to show that the Ceylonese are not quite as backward in industrial pursuits and in enterprise, as they are sometimes represented to be; that they have advanced with the times, and that there is in them the making of what their too hasty critics lament they do not intuitively become.

As we have said—and we have gone very far afield after we said it—the Ceylonese have not yet shown the skill and enterprise necessary for putting their raw products to all possible uses, and for pushing the sale of them in the best possible markets; but the advance they have made in the taste for agriculture and the arts is hopeful. Ceylon yet imports prepared Chocolate and Coconut confectionery, and has perhaps not yet even tasted Coconut Butter. It is time she bestirred herself, and added to her industries. In the Coconut palm the Island possesses an inexhaustible mine of wealth; and with the acquisition of scientific knowledge, Ceylonese might find new uses for its products which would increase its value. The extended cultivation of Coconuts—there is a larger acreage under this product here than under Tea, Coffee, Cinchona, Cocoa, Cardamons and Cinnamon combined, while it is not like Cinnamon a stranger to Southern and Western climes—has naturally lowered prices, especially for the great export of Oil. The mischief has been aggravated by the discovery of cheaper substitutes, both as lubricants and illuminants—as witness our own growing consumption of Kerosine Oil. Our hope should lie in putting the Nuts to new uses. Already, the demand created by the manufacture of confectionery in at least two Mills has helped prices; and from recent information the business is likely to expand. It is rumoured that the establishment at Veyangoda is at once to be doubled in size; and if the popularity for this manufacture grows, other competitors might enter the field. Then, if the efficacy of the substitute for animal butter is once established, the demand for it will be practically illimitable. The chemical and engineering knowledge for entering the

lists as competitors in such manufactures may yet be wanting to us; but why should not experiments be made to improve old familiar products? Copperah Oil turns rancid because of its careless manufacture; efforts might well be directed towards ensuring greater purity and more lasting qualities for the hand-made Oil, which is so widely used in cooking food. In sweets, too, much might be done, and the demand for them elsewhere be stimulated by making them known and appreciated here. The greater is the need for stimulating the demand, in view of the continued extension of Coconut cultivation.—Local "Examiner."

TEA NOTES.—DEHRA DUN, April 9th.—This time last year we had made thousands of pounds of tea; whereas this year we have hardly made a pound, it is the worst year it has ever been my misfortune to see. Some gardens are burnt already, and look worse than they generally do just before the rains.

DARJEELING, April 11th.—Rain at last! Gauged '85" yesterday. First good shower for seven months will do a lot of good all round. Small amount of leaf coming in throughout the district. Tea being manufactured fairly flavoury, but no tip.—*Indian Planters' Gazette.*

the tendril is young it moves round as it were in search of a support; but whenever its under-side comes in contact with a solid body, an expulsion of water from the cells of the irritated side occurs, and a contraction of the cell-wall follows, which causes the tendril to curve round the support which has stimulated it: as a result of this curvature a new part of the under-side is brought into contact with the support. Expulsion of water and contraction of cell-wall follows and results in a continuation of the curvature which thus goes on as long as the tendril grows in length. The periodic movements of leaves are due to unequal growth caused by diminution or increase of light and temperature. Such movements are illustrated by the opening during day and closing at night of many flowers, and the expanding and drooping of leaves, and are caused by unequal growth of the upper and under surfaces. Floral leaves open by epinasty, that is by the more rapid growth of the upper or inner surfaces, and close at night by hyponasty, that is by the more rapid growth of their lower or outer sides. Exposure to light renders the petals epinastic, to darkness hyponastic. Sometimes the reverse is the case, and then the flowers close by day and open by night.

The cabbage produces flowers epinastic by day and hyponastic by night.

Examples of flowers which are hyponastic by day and epinastic by night are the convolvulus and balsam.

Besides the movements of plants due to the phenomena of growth, there are other movements—sometimes called movements of variation—exhibited by mature leaves, or portions of mature modified leaves. These movements are due to stimulation, and when the sensitive organ is irritated, an expulsion of water from the cell-cavities of one side of the organ into the intercellular spaces occurs; the result is a contraction of the cell-walls of the irritated portion. But these movements in mature organs may also be spontaneous.

In the following plants the movements are due to irritation:—The sensitive plants (*Mimosa pudica*) which brings its opposite leaves together. Sundew (*Drosera*) exhibit these movements in its tentacles or modified leaves.

Spontaneous movements in plants are such as are not due to external irritation. The lateral leaflet of *Desmodium* (*Hedysarum gyrans*) commonly called the telegraph plant, belonging to the order Leguminosae, show a constant slow motion both in darkness and light. This is an East Indian plant which grows freely in Ceylon. These spontaneous movements are due to rapid changes in the state of turgidity of the cells.

NOTES FROM A TRAVELLER'S DIARY.

The cultivation of the cotton plant has not yet widely spread in places where it ought to, and the existence of a ready market in the island now for its

lint does not seem to be generally known to the poorer classes of agriculturists in the interior parts of the island. The interviews I had with these classes of natives during my travels, bore evidence to this fact.

Provision has been made, I believe, for buying up cotton grown by the villagers, through local agents; but I am afraid that it will not be an easy matter to induce these interior people to take up the cultivation of the plant unless "the Moorman" comes to our aid. It is generally known that the Moorish traders are most industrious, and they go far into the interior villages in search of native products, such as arecanut, pepper, &c., and give in exchange clothes, curry stuffs, &c., which the villagers are greatly in need of. These traders often pay money for these products. The Moormen must be encouraged to hunt for cotton also and I am sure they will not fail to find a few pounds of cotton lint in almost every house in the interior.

Much of the land in the Seven Korales in the North-Western Province appear to be well adapted for cotton cultivation. At a place called Munemale, which is about 14 miles distant from Kurunegala, I saw some beautiful specimens of kidney cotton plants growing almost wild. The plants were loaded with blossoms and gave promise of a good crop.

Balala, which is about 32 miles distant from Kurunegala, seems to have once been a centre of the cotton industry. Cotton of the Tinnevely variety is grown here in chenas, and it is spun and woven into cloth in native looms. A man at this place had several bags of the lint which he was keeping for spinning and weaving into cloth. The fact of his possessing so much cotton is not known to many, as he keeps it a secret.

Much is being done for the spread of cotton cultivation through the village schoolmaster. Theoretical agriculture is now taught in every Government Boys' school, and much valuable information published in the local Agricultural Magazine is also imparted to these boys. I was greatly pleased to find that several intelligent schoolmasters have attached small experimental gardens to their schools with a view to giving the boys lessons in practical agriculture. Cotton, Dhall, &c. are cultivated in these gardens. Education of this nature cannot but be of much use to the boys and of great benefit to the general community.

Many people say that the schools of agriculture and the schools for training teachers should go together. This, I think, is a very good idea, for then every trained teacher would be a scientific agriculturist as well. It is very important that every schoolmaster should have an elementary knowledge of Agriculture in all its branches, without which I fail to see how he can satisfactorily teach agriculture to his boys.

In Upper Hewaheta, I watched with interest some native looms at work. The cloth woven in these loom

is of a coarse texture, very strong and durable. The work is also done much quicker than I expected. I have ordered for a model of one of these looms, and I hope to send it to the Agricultural School Museum as soon as I get it. At Udagama, in Upper Hewaheta, I was shown a cotton plantation, belonging to a native carpenter, which is about an acre in extent. The plants which were of the Egyptian variety were about 3 months old and they were growing well.

(To be continued.)

NOTES FROM EXPERIMENTAL STATIONS.

NINTAVUR, 27th March 1890.

The whole of my experimental garden—consisting of 35 acres of paddy, 8 acres of cotton, and 3 acres of Native and English vegetables—is under crop. The crops are healthy and are growing in the most satisfactory manner. The Director of Public Instruction inspected my work on the 17th, and having compared my crops with those of the neighbouring cultivators, found them healthier and more robust. Five acres of paddy which I transplanted are looking well. The Director after looking into the accounts expressed the opinion that my cultivation should prove highly remunerative. I sowed my paddy on the 23rd of January, and the plants are now in ear. The following remark by our worthy G. A., Mr. Elliott, is of great encouragement to me:—"I inspected Mr. Chelliah's field this morning and found it flourishing and looking very much better than the neighbouring ones." As I knew that my land contained very little lime and too much organic matter, I applied 40 bushels of burnt lime to 30 acres of land just before sowing. Usually when the plants are about two or three weeks old, caterpillars prey on them and do much damage, and the plants of my neighbours were this year much damaged by these worms, but to my great surprise I have found none in my field this year, while my neighbours have removed these worms from their land literally by the basket-load.

There are four varieties of cotton in my gardens, and they are all coming up well. Some of them have both pods and flowers.

The twenty climax ploughs and the winnowing machine ordered by Mr. Elliott from Massey & Co., of Madras, arrived at the end of last year, and I have had numerous applications for ploughs in my neighbourhood.

S. CHELLIAH,

Agricultural Instructor.

OCCASIONAL NOTES.

Mr. Chelliah, the able Agricultural Instructor at Nintavur, writes at length on the subject of evil eye, citing cases where most disastrous and even fatal results were brought about by the power of the human eye, which he defines as "the vehicle through which the magnetic fluid of the body freely passes, that magnetic fluid having an inherent power in it which can somehow or other affect other bodies." Much as we would wish this abstruse subject to be thrashed out, we regret that we cannot open our columns to the discussion of the subject in an Agricultural Magazine. We trust Mr. Chelliah's contribution on this subject, which he has evidently thought much on, will not be lost to those who are interested in the question.

We are fortunate in securing the promise of a valued correspondent whose time is mostly spent in travelling about from place to place, and moreover one greatly interested in matters agricultural, that he will send us regularly, notes of his observations and the information gathered in his journeyings to and fro. These ought to prove very interesting, coming as they often will from places far remote, and from which little

news, especially of an agricultural nature emanates. The first instalment of "Notes from a Traveller's Diary," appears in the present issue.

GENERAL ITEMS.

Cattle murrain is still prevalent in many parts of the Island, especially in the Eastern Province; but Colombo and the vicinity have been almost quite free of the epidemic.

Some very severe thunderstorms passed over Colombo during the second and third weeks of April, accompanied by heavy down-pours of rain. These showers were very welcome to vegetation, but the heat is still great.

The School of Agriculture re-opened on the 15th of April, and work is in full swing again.

Reports reach us of coconut trees in the Eastern Province being attacked badly by caterpillars; and parts of Colombo too show traces of their ravages.

Prof. McAlpine, who last year brought out a translation of Stebler's remarkable book on the best forage plants, has just published a handbook on the grasses, which has been favourably reviewed by all the leading papers in England. He has discovered a method by which the commoner pasture grasses can be identified by their leaves. Hitherto few have been able to make examination to any good purpose, except in the period of inflorescence.

Several Dutch firms have commenced the manufacture of bamboo-furniture, which can be made very cheaply in Holland, as her Indian Colonies abound in the raw material. The furniture is also exported to France, Germany and England.

"In the Science of Irrigation" says the *Grocer's* criterion in an article on Japan rice, "no people in the world are more skillful than the Japanese, and their systems of sluices, conduits, dams, floodgates and other conveyances for water in many localities are wonderful in the ingenuity of their construction."

In more than one place in India it has been decided to adopt inoculation for the prevention of anthrax or splenic fever, the means recommended by Pasteur-

A Shropshire ewe, belonging to Mr. Blakeman, Haywood Lane Farm Market, Drayton, gave birth last month to the unprecedented number of seven lambs.

Egypt is evidently re-awakening to a sense of the importance of agriculture, and seeks the aid of scientific agriculturists to lay the foundation of a system of agricultural education and to improve the methods of cultivation. In our last issue we noticed the appointment of Mr. S. W. Wallace as agricultural adviser to the Government. We now hear of Mr. James Kerr who passed through the agricultural and scientific classes at the 'Edinboro' University, leaving for Egypt to assume the duties of assistant manager to the Aboukir Land Company, whose estates lie along the coast near Alexandria.

The *Straits Times*, referring to pine-apple leaf fibre, says that the Chinese weave the fabric into linen, and that it was long used in certain parts of India for making nets; while in the Philippines it is manufactured into a cloth of superior strength and fineness called Pina. Mixed with cotton or wool it is thought that pine-apple leaf fibre could form a good substitute for silk. A patent has been taken out for the production of thread from it. The leaves are best suited for extracting fibre after the fruit has ripened, so that the fruit crop need not be interfered with. The cultivation of pine-apple is vigorously pursued in the Straits Settlements.

experiments carried on at Uva in 1887 as reported in the "Times" have proved to be very encouraging. "Seed was given to Dambewinne R. M., who interested himself in the experiment, and he distributed amongst various cultivators in Udakinde, sowing a fair extent himself with the grain. The result has exceeded expectations, for not only is the barley grown in Uva equal in weight and fullness to the home-grown article, but it is found to be very much more prolific and profitable than paddy." The sample of barley which was exhibited by the R. M. was said to have weighed 56½ lb. per bushel, whilst the average in England is said to be 54 lb., and the finest sample of malting barley (in one year) in England weighed 57 lb. per bushel according to Prof. Tanner. This shows that the Uva district is capable of producing barley of superior quality. The cultivators had hardly any practice to guide them in this instance, but when used to it and the character of the plant better understood, there is no doubt that still better results would be obtained.

The soils best suited for the cultivation of barley are moist, strong, not too cohesive soils, perfectly free from weeds; and such soils are not absent in this island, in the milder climates. Moreover, barley is known to be a surface feeder, and it takes up materials only from the surface soil.

The seasons should be regulated as those for paddy, as an excess of rain induces the barley plant to run into a strong growth of straw. This may be arrested with suitable treatment, but it is always advisable to remedy it by regulating the season than by any other treatment. The regulation of the season is one of the most important points which should be borne in mind in making the goiyias to adopt any new cultivation. If they fail in their first experiment, by whatever cause it may be, it is a difficult task to make them try it again, or believe in the true cause of the failure.

In case the regulation of the season fails, and there are apprehensions of rain, the crop could be saved by a judicious treatment of an application of a slight dressing of salt to the soil, sown as soon as the seed barley has been put in. The good result from this proceeding is due to the steady check which the salt gives to vegetation, inducing a slower, steadier and firmer growth, tending to throw the crop into a seed-bearing condition.

Another important condition on which the success of a crop of barley depends is the proper preparation of the seed bed. All grains do require a properly prepared seed bed, but barley is said to be more sensitive in this respect. From some experiments recorded by Prof. Tanner on the cultivation of barley in England, he shows that in one instance where barley was sown on a well-prepared plot and a badly-prepared plot on the same field, the yield was 40 bushels and 24 bushels per acre respectively, and the weight of a bushel of grain was 58½ lb. and 54 lb.

Several reasons go to commend the cultivation of this grain in such places as Uva where the climate is

agreeable, among which may be mentioned the suitability of the soil, the non-requirement of irrigation water, and the good crops and prices obtainable for the product.

The large yield obtained during 1887 is thus reported in the *T. A.*—"Messrs. Fernando who obtained the 2nd prize and sowed less than 5 bushels over 8 acre obtained 150 bushels equivalent to about 33 fold or 13½ bushels per acre." This serves as an example of crop obtainable.

As there is a demand at the local brewery, there is no doubt that this grain could be added with advantage to the list of those cultivated in Uva.

DHALL.

Almost all kinds of soil are suitable to Dhall cultivation, but as the plant belongs to the natural order Leguminosæ, land in which lime predominate most favours successful growth, and analyses tend to prove this. The villagers about Batticaloa having seen that the plant can be grown without much trouble and attention, have taken to the cultivation of dhall on the plots of land surrounding their dwellings. They use the seed of the legume, of which there is nearly a constant supply throughout the year, for consumption after its preparation into a most wholesome and palatable curry. In cultivation, the seed is either first sown broadcast in a prepared bed and then transplanted when the plants are about a foot and half high, or the seeds are drilled in rows at a distance of 3 feet by 2 yards. The work of transplanting is generally done in the evening. The seedlings are watered morning and evening every day for about a fortnight, and well-rotted dung is the only manure required. It is best to begin the cultivation of dhall when the north-east monsoon sets in. The trees begin to flower when about 3 or 4 months old, and when the fruits are dry they are plucked and exposed to the sun. The seeds are separated from the pods, and the husk removed from the seed as follows. The dried seeds should be soaked in water made muddy with red earth which is very common in this district, and allowed to remain thus for two hours. They should then be removed from the water and placed in a heap, and the muddy water gradually sprinkled over the heap, which should be left standing for a night. Next morning the heap must be broken up and the seeds placed in the sun to dry. The earth should be removed by winnowing and the dhall seeds collected and put into a pounding machine, consisting of two grinding stones, one fixed and the other movable; the latter working round an iron rod fixed to the former. The seeds are fed into the space between the iron rod and the upper grinder which is then set in motion by a handle. The seeds get in between the two surface of the grinders which meet each other and the beans are broken up. The broken seeds are now again winnowed and the husk removed. Any sand or

mud or other useless matter will be also removed now, and the pure seeds without husks left. The seeds now termed "dhall" command a ready sale in the market, and it is found that dhall subjected to the process I have indicated for removing the husk, namely of soaking, is of excellent quality; the process inducing incipient germination which imparts a peculiarly agreeable flavour to the seed. With more suitable and convenient machinery for crushing and winnowing larger quantities, sufficient for export, may be produced without difficulty.

S. CHELLIAH.

ANIMAL PARASITES.

(Continued.)

The order *Teniada* derives its name from the Greek word for a ribbon, owing to the elongated flattened structure of the worms which resemble ribbon or tape in appearance. The commonest of the three tape-worms which occur in man is the *Tenia Solium*: the adult stage is passed in man, while the cystic stage is passed in the pig. In man the worm is found many feet or even yards in length, consisting of a number of flattened joints which incline to taper towards the anterior extremity and end in a point, where we find the head with its four suckers and a collection of flinty hooklets for attachment to the alimentary canal. As mentioned previously it is the head that is the real animal from which the joints are produced by budding, and the great object in the treatment of cases of tapeworm in man is to remove the head, for while the head remains in the body, the animal will continue to grow by putting out flattened joints. The eggs which are produced by the joints which contain the reproductive organs, cannot be developed in the body of man, but have to enter that of some warm-blooded animal before they can be "hatched." In cases of tape-worm in man, the flattened joints which are loosely attached to one another, are passed out at intervals, and the eggs are thus liberated to be blown about or to float in water till they are taken up by the pig. No sooner the egg enters the stomach of the pig the little embryo is produced, which bores into the muscles of the animal or into some solid organ. Once the embryo reaches the place where it intends to remain, it puts forth from its hinder extremity the bladder or cyst filled with fluid which gives it at this stage the name of "cystic-worm." While the embryo is boring its way through the tissues of the body of the pig great pain is evinced by the latter animal, but when the embryo comes to a state of rest no more discomfort is apparently felt. The presence of these cystic-worms in the flesh of the pig causes what is commonly known as "measly pork"—the disease in the pig being known as "measles." The cystic stage of *Tenia solium* which occurs in the pig is known as "cysticercus cellulose." To find whether a

is suffering from "measles," it should be examined

under the tongue and eyelids. If it is measly, small white cysts will be found there. Even after the animal is killed and made into pork the cysts can be discovered if the meat is bad. Such meat should be burned. If a piece of pork containing a cyst be eaten by man, unless the meat be very well cooked, it will be the cause of tape-worm (*Tenia solium*); for the cyst will fix itself in the alimentary canal of the man, throw off its cyst, and become at once the "head" of the full-grown tape-worm. Now it will go on producing buds from its posterior extremity, till it assumes the ribbon or tape-like form which characterizes the full-grown tape-worm.

IRRITABILITY OF PLANTS.

The irritability of plants may be conveniently studied under the two heads of (1) Nutation, or movements of organs due to growth, and (2) Irritability of mature organs. Under the first heading we may notice that the different surfaces of plants are usually unequal in growth, that is that one surface grows faster or slower than the other. This inequality of growth may be due to internal or external causes. The internal causes, aided essentially by external causes, such as light and gravitation, produce for instance the phenomena known as hyponasty and epinasty. Parts of plants are said to be hyponastic when they grow more rapidly of the under than the upper surface, and epinastic when the opposite condition obtains. The plumule or rudimentary stem of dicotyledons is at first epinastic, *i. e.*, it grows more on the upper surface and consequently tends to bend downwards, and then afterwards hyponastic, *i. e.*, it grows more on the under surface, and hence tends to bend upwards and grow erect. Again foliage and most floral leaves when in bud are hyponastic, but subsequently unfold by epinasty. The movements in plants caused by epinasty and hyponasty, or of the more rapid growth of the right or left of a growing organ are included in the term simple nutation. If the movements of a growing organ are in every direction, *i. e.*, if the organ revolves in a spiral manner in consequence of the more rapid growth of each of its sides in succession, it is said to exhibit revolving nutation. Twining or climbing plants (*e. g.* the bean) show revolving nutation very plainly. Twining plants as a rule twine to the left, though a few do so to the right. The bean and convolvulus, for instance, twine to the left: while the honeysuckle twines to the right.

But unequal growth may, as before stated, be due to external causes or influences, which are termed paratonic or kinetic, and examples of these are the movements in tendrils and the periodic movements of foliage and floral leaves. Now tendrils exhibit revolving nutation also, but while in twining stems it is immaterial which side comes in contact with a support, in the case of tendrils, only one side, namely the under side, is capable of becoming concave when brought into contact with a solid support. THE SILKWORMS OF INDIA AND SERICULTURE IN CEYLON.

"THE SILKWORMS OF INDIA"—CASUARINAS AS FOOD FOR SILKWORMS—AND FOR OTHER PURPOSES—SERICULTURE IN CEYLON, ITALY, AND INDIA—VARIETIES OF SILKWORMS AND THEIR FOOD.

NANUOYA, April 16th.

HAVE read the pamphlet issued from the Indian Museum on "THE SILKWORMS OF INDIA" with more than usual interest, because of the astonishing paragraph which recently appeared in the

Observer, quoted from a Madras paper, indicating that a plantation of young *casuarinas* had been specially prepared for silkworms to feed on, and that a member of the Council of Government, was personally watching the experiment! No premonition of such an experiment had been seen by me, and the last idea which would suggest itself to my mind is that of silkworms, which specially attack succulent leaves, finding congenial food in the pine-like foliage ("whorled teeth or bristles") of the *casuarinas*. A much more likely idea to my mind would be that of carding, spinning and weaving the bristles as those of the true pines have been in America for sackcloth. We have all the varieties of *casuarina* I believe on this estate and we never saw an insect of any kind of them until had read the Madras paragraph. Then, curiously enough, I noticed, during a morning walk, the tops of haladozen young plants affected by that queer little butterfly, that hops about a branch rather than flies, when disturbed. A white scum accompanied the insects. The whole were easily removed, and on no other *casuarina* has a single insect been observed. And yet, now that I look at the qualities attached to the *casuarina* foliage, especially that of coppiced trees, as a fodder for cattle, my surprise ought to be modified. Baron von Mueller states that beside the value of the *casuarinas* in binding drift sand and rendering it fertile, in being quick

of growth and most valuable for fuel, pastoral browse on the foliage, which is acidulous from a crystalline substance allied to bi-citrate of lime. Giles, the Australian explorer stated that the dromedaries used by him delighted in getting the branchlets of some species for food, and von Mueller says that all the species can be pollarded for fodder. Has the foliage ever been utilized in this direction in Ceylon? If not, why not? *C. equisetifolia*, the species so common and so beautiful in Colombo, is stated to be one of the best and fastest growing fuel and timber trees in the world. A few years ago I noticed an experiment at Matale with silkworms from Japan, introduced by Mr. Robert Fraser of Wariapola. The impressions I received were, that, with the aid of the Blackman fans and other expedients, the worms could be reared and utilized, provided enough of mulberry leaves could be grown for these very voracious creatures, and provided also that an abundance of very cheap labour were available. In Italy plenty of cheap labour and scientific supervision seem to be combined, for we read of one establishment in which 600 peasant girls are supplied with costly microscopes for the discovery and removal of the parasites to which the precious worms are liable. In Bengal the hot steamy atmosphere is specially favourable to the growth of mulberry, several crops of leaves in the year being yielded; but, although labour is cheap in India, careful and scientific supervision is not bestowed on the pursuit, which accordingly is in a low and decadent state. Indian silks can only in rare cases, it seems evident, compete with those of China and Japan, Italy and France:

There are many varieties of silkworms in India which feed on numerous other plants beside the mulberry, only two of which seem to be indigenous to Ceylon. Amongst the plants enumerated we have looked in vain for any mention of the *casuarina*, but it seems probable that in future editions it must find a place. Meantime we may quote the names, vernacular and scientific, of the various plants, some common to India and Ceylon, on the leaves of which the worms feed or are reared, first noticing that in

the pamphlet there is quoted from Riley's Manual of Silk Culture in the United States a most elaborate account of the cultivation of the *Bombyx mori* and of all the processes in production of silk. Those inclined to try experiments ought, therefore, to become possessors of this well illustrated pamphlet: *Bombyx textor* is only one of the worms said to be found in Ceylon. Passing over this and several other worms which feed on mulberry leaves, we come to the worm which produces the tusser silk, *Antheraea mylitta*. Of this worm it is stated:—

This insect, which is very variable in appearance and has been described under a number of synonyms,* feeds on many different plants,† and is found in a wild state in jungle land up to four or five thousand feet elevation‡ all over India: a closely allied or identical form is also found in Ceylon.§ The cocoons always command a price in the market, and are accordingly collected by jungle tribes wherever sufficient quantities can be found to be worth carriage, while the insect is regularly cultivated on the Central Indian plateau for the production of silk. The moths emerge from their cocoons in the beginning of the rains (June), copulate and lay eggs; from these eggs emerge caterpillars which become full-fed and spin cocoons which produce moths about August; these moths lay eggs which produce the worms of the second generation, and these worms spin at the end of the rains (September), yielding the cocoons which in their natural state remain on the trees throughout the winter and produce moths in the commencement of the following rains (June.)

The cocoons, which are each attached to the food-plant by a silken stem of singular strength and neatness, are hard and compact in structure, and contain a large amount of coarse, strong, buff-coloured silk, inferior in brilliancy only to the silk of the *Muga* worm (*Antheraea assama*). The cocoons can be reeled, but have first to be subjected to the action of some powerful solvent (e. g., caustic potash) to separate the threads.||

* Tusser=*Antheraea mylitta* (Hübner, Walker, Moore, Aurivilius, Wardle, Rondot, &c.)=*Phalena* (*Attacus*) *mylitta* (Drury)=*Attacus mylitta* (Blanch)=*Bombyx mylitta* (Fabr. and Oliv.)=*Phalena paphia* (Cramer and Roxburg)=*Antheraea Paphia* (Moore and Beavan)=*Saturnia mylitta* (Westw.)=*Saturnia paphia* (Helfer.) For details of the synonymy, see *Catalogue of the Moths of India* (Oates and Swinhoe), p. 228, Calcutta, 1889. Besides the above, which have long been admitted as identical, Hutton described *Antheraea nebulosa* as a distinct form from Ohta Nagpur and Central India; Hutton's type specimen is in the Indian Museum, and is obviously only a dark-coloured individual of the common tusser.

† Besides the trees—*Shorea robusta* (sal) and *Terminalia tomentosa* (saj)—on which the tusser is usually reared, Wardle, in his *Wild Silks of India*, notices that the following are food-plants: *Rhizophora calceolaris*, *Terminalia alata glabra*, *Terminalia catappa*, *Tectona grandis*, *Zizyphus jujuba*, *Bombax heptaphyllum*, *Careya spherica*, *Pentaptera tomentosa*, *Pentaptera glabra*, *Ricinus communis*, *Cassia lanceolata*, *Lagerströmia indica*, *Carissa carandas*, *Terminalia arjuna*, and *Ficus benjamina*; while Cameron in his report for 1887-88 states that in Bangalore tusser has been found to feed on *Dodonea viscosa*, *Weberia corymbosa*, *Shorea talura*, *Terminalia arjuna*, *Anogeissus latifolia*, *Cipadessa fructuosa*, and *Canthium didymum*.

‡ The late Otto Möller noticed that he had never met with the species in Darjiling (7,000 feet), though it is common at the foot of the Darjiling hills.

§ Described by Moore, in his *Lepidoptera of Ceylon*, London, 1882-88, under the name of *Antheveea cingalesa*.

|| One of the greatest difficulties in reeling tusser silk, after the cocoons have once been softened, is to make the separate strands cohere in the reeled thread; this difficulty does not occur in the case of mulberry silk where, unlike the tusser, the cement is only softened in the reeling basin, so that on again hardening it serves to glue the strands together.

Both the cement with which the caterpillar hardens the walls of its silken cocoon and also the fluid with which the moth afterwards softens this cement, prior to working its way out by the help of its wing spines, appears to be secreted in the alimentary tract and to be of excrementitious origin.

In Ohta Nagpur the worms are reared on *Shorea robusta* (sal, or sakoona), and *Terminalia tomentosa* (saj, assun, asain, or en); cocoons are also found on *Zizyphus jujuba*. In the Central Provinces they are chiefly reared on *Terminalia tomentosa*.

In his report on Silk in Assam (February 1884) Stack writes:—

"The wild silkworm called *kutkuri* is believed to be the same as the common tusser of Bengal. Its food is principally the *kutkuri* (*Tangueria spinosa*) from which it takes its name, or else the plant called (erroneously) the wild Rhododendron (*Melastoma malabaricum*), the Assamese name of which is *phutuka*. It has been cultivated in the palmy days of the Assam silk industry, but it is now almost entirely neglected as being inferior to *muga*, and, also, perhaps, because it yields only three* broods in the year. Its habits are now known only to a few old people in Jorhat.

Mr. Buckingham, to whom I am indebted for most of my information about this worm, says that the *kutkuri* is common in the wild state in the neighbourhood of Jorhat. It is also common in Cachar, but there also no use is made of it. Some worms reared in June and July took rather more than a month from the laying of the egg, to the spinning of the cocoon.

"The worms were fed on the *phutuka*. Worms put outside while very young were speedily devoured by ants, but if kept indoors till the second molting, they were then found to do very well on the bushes. Mr. Buckingham adds:—'I reared ten worms in this way, and all except one made their cocoons between the leaves of the shrub, one solitary worm descending and making its cocoon in the grass. The native had previously informed me that this wild species of worm was less liable to the attacks of crows, bats, &c. than tame species were, and it was curious to watch how the worm, at the slightest show of danger, let go the leaf or stem with all its front legs, hanging on by its holders behind, and in this position, with its head slightly curled round and its front legs well tucked up, it took an experienced eye to detect the difference between the leaf of the tree and the worm.'"

"The wild silkworm called *Salhi* is also a species of tusser. It is called *Deomuga* by the Kacharis, but must not be confounded with the *Deomuga* proper which is described below, and which is a *Bombyx*. The *Salhi* worm feeds on the *Kamranga* (*Barringtonia racemosa*) and the *Hidal*.

Tusser cocoons are met with extensively, in a wild state, throughout the submontane districts of the Punjab, chiefly on *Zizyphus jujuba* (the *ber* tree). It does not appear, however, that the insect has ever been reared otherwise than experimentally for the production of silk.

We next notice "Eri," or *Attacus ricini*:—

This is a multivoltine silkworm which is fed on the leaves of the castor-oil plant and reared entirely indoors in Assam, much in the way that the mulberry worm is reared in Bengal. It is cultivated throughout the whole of Assam, particularly in the submontane districts, the industry being mostly in the hands of non-Hindu tribes of low caste.

A most complete account of the insect has been given by Stack in his report, dated February 1884, on silk in Assam. The following therefrom is quoted *verbatim* from his report, foot-notes only being added in cases where further information has been obtained:—

"The eri worm (*Attacus ricini*) derives both its scientific and its vulgar name from its attachment to the castor-oil plant (*Ricinus communis*), called *eri* in Assamese. It feeds also on the *keseru* (*Heteropanax fragrans*) and there are several other trees, as the *gulan-cha* (*Jatropha curcas*), the *gomari* (*Gmelina arborea*) and even it is said the common *bogri* or *ber* tree (*Zizyphus*

* In Central India tusser yield but two.

jujuba), which the worm can thrive on in its later stages, if other food is not procurable in sufficient quantity. The *eri* worm is a multivoltine, and is reared entirely indoors. The castor-oil plant grows abundantly in the ryot's garden, springing up from dropped seed in every little patch of unoccupied land around his house. The tending of the worms devolves principally upon the women of the family, and goes on all the year round. As many as eight broods can be obtained in twelve months, but the number actually reared never exceeds five or six, and depends a good deal upon the quantity of food which chance has provided for the worms, since no care is taken to ensure a supply by planting out trees.

Their supply of food is occasionally intercepted by swarms of caterpillars* appearing on the castor-oil plant about the month of June. These must be carefully removed from the leaves that are given to the silkworms, and the leaves themselves washed in water. It is at seasons like these that the leaves of a variety of trees are used as substitutes for the favourite food of the worm.

We next notice "Muga," *Antheræ assama*:—A semi-domesticated silkworm which is cultivated in the open in the Assam Valley, much in the way that *tusser* is cultivated in the Central Indian plateau; though the *muga* is somewhat more domesticated than the *tusser*, its eggs being hatched, and its cocoons spun indoors.

It is reared on the *sum* tree (*Machilus odoratissima*), and on the *suahu* tree (*Tetranthera monopetala*), but will also feed on the leaves of other trees, e.g., the *mezankuri* (*Tetranthera polyantha*), and the *champa* (*Michelia* sp.) upon both of which it is said to have been reared in considerable quantities in former years, the silk produced by the worms fed on these trees being known as *mezankuri* and *champa* respectively, and being considered as whiter and of better quality than ordinary *muga*.

The following is extracted from Stack's Report on Silk in Assam dated February 1884:—

"The scientific name of the *muga* silkworm (*Antheræ assama*) denotes its peculiar connection with Assam..... Its Assamese name is said to be derived from the amber colour of the silk, and is frequently used to denote silk in general, so that *erimuga* means *eri* silk, *kutkuri muga*, *tusser* silk, and so on; the genuine *muga* being distinguished by the title of *Sompattia muga*, or silk yielded by the worm that feeds on the *sum* leaf. It is a multivoltine worm, and is commonly said to be semi-domesticated, because it is reared upon trees in the open air; but in fact it is as much domesticated as any other species, being hatched indoors and spinning its cocoon indoors, while during its life on the tree it is entirely dependent on the cultivator for protection from its numerous enemies. The *sum* tree (*Machilus odoratissima*) furnishes its favourite food; but in Lower Assam it is extensively bred on the *suahu* (*Tetranthera monopetala*). The leaves of certain other forest trees the *dighlate*. (*Tetranthera glauca*), the *patichanda* (*Cinnamomum obtusifolium*) and the *bamroti* (*Symplocos grandiflora*) can be eaten by the worm in its maturer stages if the supply of its staple food begins to fail; but the *sum* and the *suahu* are the only trees upon which the worm yielding the ordinary *muga* silk (as distinguished from *champa* and *mezankuri*, which will be mentioned hereafter) can be permanently reared. The *sum*-fed worm is considered to yield the more delicate silk, and *suahu* trees on the edges of *sum* plantations are generally left untouched, though small plantations of *suahu* only may occasionally be met with.

"An account of *muga* silk would not be complete without a few words on the two varieties assumed by

it when the worm is fed on the *champa* (or more properly *chapa*) and the *mezankuri* or *adakuri* (*Tetranthera polyantha*). *Champa* silk seems to be quite forgotten now. It is described as a very fine white silk, which used to be worn only by the Ahom kings and their nobles. *Mezankuri* silk is still to be procured, but with great difficulty. In 1881 there does not seem to have been a single piece obtainable in Jorhat. One of the reasons alleged for this falling off is that the new rules restricting clearances in the forests are unfavourable to the growth of the *mezankuri* tree. This tree springs up spontaneously in abandoned clearances, and it is in this early shrub-like stage that it is fit for the worms to feed on. In its second year the worms fed on it give coarser silk; in the third year the silk is hardly distinguishable from the common *muga*. Thus the mature tree is quite out of the question, and as the *mezankuri* is never cultivated, forest clearances were the only places where the breeders could look for young trees. When fed on the *mezankuri*, the *muga* worm spins a fine silk of almost pure white, about thrice as valuable as the common *muga*—in fact the most costly of all the silks of Assam. The thread was selling at R24 the seer in Jorhat in 1883. This silk is altogether an article of luxury.

Although sericulture is not likely, we suspect, to be added to the successful industries of Ceylon, there is popular as well as scientific interest in such a pamphlet as that briefly noticed, in which so many silk-producing insects and the trees on the foliage of which they feed are mentioned.

TEA IN AUSTRALIA.

GOOD PROSPECTS OF INCREASED DEMAND FOR CEYLON AND INDIAN TEA.

The S. S. "Arcadia" brought among other passengers Mr. H. M. Rowbotham of Rowbotham & Co., Tea Brokers, Sydney, with whose Tea Circular as quoted from mail to mail, our readers are generally familiar. Mr. Rowbotham has been absent from Ceylon for eleven years, so that very considerable changes both in Colombo and upcountry await his observation. In his old district, Dimbula, as we have mentioned to him, it will be difficult soon to find a coffee-bush (save in the Agra division) so prevalent has tea become. Letters are likely to appear in the Melbourne *Age* and a Sydney paper on "Ceylon Revisited" which may increase the interest in our staple; for Mr. Rowbotham, we are glad to say, believes that we are on the eve of a very considerable development in the Ceylon and India tea trade with Australia. We are naturally interested to learn that the China tea trade with the Colonies is steadily falling in repute—the financial losses of late have been very considerable—and Foochow dealers are largely blamed, the explanation apparently being that seeing the end is approaching, they have begun, in regard both to England and Australia, to endeavour to make the very most for themselves in the few seasons left to them, irrespective of the consequences. At any rate, it is a good sign when Mr. Rowbotham who is now widely known as a Sydney tea-broker, sees his way to leave his business on a special mission to Colombo and Calcutta—supported by several big Colonial tea firms—in order to make all necessary arrangements for a considerable extension of business in buying and importing our own and Indian teas. One drawback presented to the Ceylon trade is the comparative dearness and occasional scarcity of freight. In the case of Calcutta, the trade is so much larger that at intervals, special steamers are run to Melbourne and Sydney with teas. These can at least get a cargo of Australian coal back, apart from copper from Adelaide, stock, wines, &c. The day may shortly come when it may be possible to fill

* Specimens of a caterpillar, reported on by Mr. Mackenzie as having proved most destructive to castor-oil plants, used for rearing *eri* in Cachar, have been forwarded to the Indian Museum by Mr. R. S. Green-shields, Officiating Director of Land Records and Agriculture, Assam. They prove to belong to the species *Achæa melicerte*, a Noctuid moth which has also been reported as destructive to castor-oil plants in Lower Bengal and in Madras. See *Indian Museum Notes*, Vol. I, pp 52 and 104.

a steamer at Colombo with tea (and some other produce) entirely for Melbourne and Sydney; but so far we have to depend on the outwardbound P. & O., Orient, and N. Lloyd's steamers having some room for our tea, the freight being higher usually than from Calcutta. Another complaint, Mr. Rowbotham indicates is the very uncertain and uneven delivery of our teas, even when described as "bulked on estate" and under one mark. He constantly finds the greatest difference between different chests in such lines under one estate mark though noted as bulked. There being no rule for "bulking" at the Australian Customs offices, this discrepancy often leads to trouble and expense, and Ceylon planters must be more careful if they wish to get favour for their teas down south. There are some of our teas, Mr. Rowbotham considers, admirably adapted to the Australian market, while others which sometimes are shipped to Melbourne and Sydney, are not at all adapted and generally make a loss for the importer. It is to endeavour to put things on a proper working basis and to prepare the way for large orders, that Mr. Rowbotham has appeared, and if he prove the harbinger of a more extensive and steadily developing tea trade with the Colonies, his mission cannot fail to be regarded with interest. He tells us that the fact of our Colombo tea market being open all the year round is a decided advantage to Australian dealers as enabling them to work with less capital, in getting supplies at frequent intervals rather than one large supply as at the opening of the China and Calcutta seasons. — We call attention to our quotations from the Circular of Messrs. Rowbotham & Co. further on.

To show the progress made in our Tea Trade with Australia, we have only to contrast the quantity shipped from 1st January to 17th April 1890, namely 446,896 lb. with that for the same period last year, 193,217 lb.—increase this year, 253,679 lb.

Of the natural order *Orchidea* there are 30 different species, the names of which are not yet ascertained. Number of species not in A. Moon's Catalogue 97, Total, 688.

Colombo, Sept. 16th.

My Dear Sir,—I received the accompanying last evening from Mr. Lear, and beg to leave to Your Excellency's decision the expediency or not of my taking to Dr. Wight at Madras the Herbaria therein mentioned. If entrusted to me I will take care after due examination, naming, &c., they shall be returned, if required, to Trincomalee by a ship of war or some other vessel whence they may be easily transported to Colombo, Kandy, &c.

The knowledge of Ceylon Botany will by their Heads, in my opinion be greatly facilitated and extended, as there are probably many new and undescribed plants among them. It will at the same time enable us to make many Addenda to Moon's Catalogue, which is in much forwardness; and as the plan is in accordance with your former views and wishes, I have little doubt of His Excellency's approbation, although I do not like to act upon that idea by at once authorizing Mr. Lear to send down the Herbaria to Colombo in time for me to take them with me to Madras.

There is just time to receive them before leaving this, as in all probability we shall sail by the 28th in the "Rahmanee," which Captain Stewart has strongly recommended me to take in preference to the smaller vessel the "Fancy."

Together with the numerous Plants and Drawings we have sent home, I think Ceylon Botany will make a good figure in print. At this time much is in course of publication in Scotland.

I cannot sufficiently thank you for your last kind letter and its enclosures to Lord Elphinstone. I perceive by a Bombay paper received yesterday that Mr. Welard has taken his passage in a steamer.

We may possibly have the pleasure of again seeing you before leaving Colombo.

Mr. Stewart Mackenzie is about to give a Regatta on Tuesday on the Kalane Ganga. Picnic, &c. Perhaps hearing this is a mystery which I ought not to have betrayed.

I am &c., very faithfully yours,

G. W. WALKER.

Botanic Garden, Sept. 15, 1888.

Dear Sir,—I have just completed my examination of the Dried Specimens and Drawings at the Royal Botanic Garden, Peradenia, and I am happy to forward for your information the order in which I found them:—

In Mr. Moon's Collection there are

Total number of Specimens	2,004
Duplicates	535
Different	1,469
Spoiled	309

In good order 1,160

In Mr. MACRAE'S Collection

Total number of Specimens	2,567
Duplicates	780
Different	1,787
Spoiled	212

In good order 1,575

In Mr. WATSON'S Collection

Total number of Specimens	480
Duplicates	60
Different	420
Spoiled	34

In good order 386

The Drawings are

Total number	546
Duplicates	78
Different	468
Spoiled	30

In good order 438

The three collections of Specimens consist chiefly of the same kind of plants, but where there is a difference, if it is His Excellency the Governor's and your wish such specimens can be selected to make either collection a greater number, and in my opinion they are worth sending to Doctor White or any other professor to be named, which is also a proceeding very much to be desired. If you determine upon so doing, I shall feel much pleasure in attending to your directions and packing up the collection in the best possible order.

I remain dear Sir, Your most obdt. Servant,
J. G. LEAR.

The Rt. Hon'ble the GOVERNOR, &c., &c., &c.
Royal Botanic Garden, Peradenia, Sept. 18th, 1888

Sir,—I have the Honor to acknowledge the receipt of Your Excellency's letter of the 14th instant with 9 seeds (not 10) of an "American Creeper" which I have sown in conformity with Your Excellency's wish, and I shall attend to them with especial care. With respect to the collection of the seeds of plants and trees peculiar to Ceylon, for Your Excellency, I humbly beg leave to say, my conviction of the general indifference paid to the correctness and quality of seeds formerly collected by this Establishment condemned those I found in the Stores, upon my taking charge, and they were destroyed with but very few exceptions.

To replace them I have now far advanced an entirely new collection, to which I will add for Your Excellency's donation to the Horticultural Society, seeds of 150 species and some very beautiful, which I collected on my late travel to Putlam, &c. I have not yet been able to ascertain when the "Agnes" is likely to leave the island, but I hope to have your collection of seeds for the H. Society ready to despatch by that vessel, with my own for Mr. Knight, and also a collection for Brahan Castle. In my opinion it is not advisable to send plants from this Island to England before November or December, but as soon after that as possible I shall endeavour to dispatch my collection in hand to Mr. Knight, and at the same time I will take care to have ready 100 plants of the Rhododendron from N. Ellia, to be sent addressed agreeably to Your Excellency's direction with a letter from me to Mr. Knight, who I am sure will with much pleasure have them properly forwarded to their destination.

A report of my proceedings shall be early sent for Your Excellency's information, and every other command from Your Excellency shall have my best and strict attention. May I here also beg permission to say for Your Excellency's information, that no step has hitherto been taken by Government to release me of the Clerk, Mr. Solomons, or to place me upon a footing to treat him as a servant, which delay puts him in a very independent situation before me, and which he fails not to show upon all occasions. I sincerely hope I need not say more to ensure his dismissal from here, than the following. He (Mr. S.) came at night (only a few days past) into my apartments, in a state of complete intoxication and used the most violent, abusive and insulting language he could possibly frame, and otherwise put me in such a

state of nervousness and fear, that I would not upon any consideration experience again, if I could avoid it. This is only a single instance from the many I could bring to prove, that he has formed a complicated scheme to annoy me. I have written to Mr. Turnour soliciting Government interference and protection, and that gentleman has suspended Mr. Solomonsz, but I trust he will not be admitted again to occupy an office in this Department, otherwise I fear a failure in the proper performance of my duties.

I have the Honor to be, Sir, Your Excellency's most obedient Servant,

J. G. LEAR.

K. W. S. MACKENZIE, Esq., A. D. C., &c., &c., &c.

Royal Botanic Garden, Peradenia, Oct. 9, 1838.

Sir,—In conformity with directions I received from His Excellency the Governor on 16th Sept., I have the honor to forward for His Excellency's information, a report of my proceedings since I took the temporary charge of the Royal Botanic Garden, Peradenia.

Finding that the Establishment had been for a long time conducted in a very disorderly manner, I commenced an investigation of the office accounts &c., and found that there was much to charge the respectability of its management. The result of that investigation I laid before Mr. Turnour, the Government Agent for the Central Province, to be forwarded by that gentleman to the Colonial Secretary; I also assisted the Assistant Government Agent of the Central Province to make an Inventory of the Government property found upon the premises; I next proceeded to place the labour of the Establishment upon a more regular and better proportioned basis, in which I have succeeded to my best satisfaction. Instead of there being sometimes 15 and at others 50 coolies employed, and the labour allowed made up either improperly, or by accident as formerly, the required number now having a conditional engagement to fulfil, are become attentive to their employ and absent themselves only upon application for leave to do so; the good effects of my arrangements in this department are daily visible and acknowledged amongst the whole Establishment with every apparent satisfaction.

I abolished labour on the Sabbath day which had been rudely continued to the period of my taking charge. I next cleared away the jungle, from many of the overgrown flower borders and roads surrounding the Garden to shew me its position, and to enable me to complete a Catalogue of the plants on the premises, which I forwarded with a plan of the Garden and a report of its then present condition to the Assistant Colonial Secretary on the 15th September for His Excellency the Governor's information.

I next commenced to clear a portion of the land, formerly kitchen garden, to enlarge that department, and about 4 acres are now added to be trenched and laid out for that purpose. I have also cut down and cleared away many large trees that were common and unsightly at the entrance of the Garden, repaired one of the principal drives and a few of the water channels. I have also commenced operations for a nursery upon an extensive scale, so as to be enabled to grow and supply the island with such useful plants as appear in demand, or promise well to repay the cultivator. I have likewise made preparations for a classical arrangement of the plants upon the following plan, which I hope will meet with His Excellency's approbation. To clear and set apart which is convenient, 24 divisions proportioned to the extent of and to receive

separately, the plants according to the classes of the Linnæan system, but not to interfere with the three beautiful natural families, Palmæ, Orchidæ and Filices which I have proposed to arrange in separate divisions appropriated to them alone: one division also for aquatic and marshy plants, one division for specimens to exemplify the natural or Jussien system of classification, and one division for an Arboretum. The kitchen garden to be enlarged as above. The orchard to remain as at present adding more choice fruits as they may be received, and a small plot of ground for an experimental garden, form altogether the basis of improvements, contemplated and in progress. I have examined the Hortus Siccus consisting of upwards of 4000 specimens, the drawings of upwards of 500, as reported upon them and dispatched, the former to Colombo, to be sent to Madras under the care of Colonel Walker in conformity with His Excellency's directions. I have trenched a portion of the old kitchen garden and sown vegetable seeds at several different periods many of which appear in a thriving state.

I have also sown seeds of nutmegs and clove trees, about 1000, which are in progress of vegetation, cleared several pieces of jungle land containing coffee seedling plants for nursery, about 10,000, picked ripe coffee, in the husk about 25 parrahs, to be brought hereafter to Government account, cleared and soiled up the Cardamom plantation about one acre, which promises an excellent crop. I have made a new collection of seeds, to be disposed of to all applicants and brought to account accordingly. The garden is at present in very confused order under the progress of necessary alterations; to complete which I beg His Excellency will be pleased to grant me the assistance of some extra labour which I applied for to the Colonial Secretary on the 2nd instant.

I have the honor also to mention for His Excellency's information that I enquired respecting the chocolate nut tree, Theobroma Cacao, of Mr. Turnour the Government Agent, Kandy, but that gentleman has not yet furnished me with any particulars. I have however compared the species flourishing so beautifully at Peradenia, with the Botanical essential characters of Theobroma cacao, and find it to coincide with that exactly. Miller, in his Botanical Dictionary mentions two principal varieties of the tree, but no specific difference according to his description; the one we have here has some trifling advantages. The following is a method of preparing chocolate which agrees with Dr. Gregory's Arts and Sciences, Miller's Botanical Dictionary and Loudon's Encyclopædia of Plants:

"The seeds when fully ripe are taken from the pods and exposed to the sun until they are thoroughly dry, when they are fit for store. They are next roasted in an iron pot over a fire and divested of their external covering, which then separates easily. The kernel is levigated on a smooth stone, or pounded fine in a mortar, a little Arnatto is added and with a few drops of water is reduced to a mass and formed into rolls for use. This simple preparation of Chocolate is the most natural and best"—Gregory. The fruit in the Royal Botanic Garden is not yet ripe to make a trial according to the above receipt, but it shall have my best attention as early as an opportunity offers, and I will report the result in due course for His Excellency's information.

The tree bears two crops annually: one ripens in June, the other in December; the bearing trees in the Royal Botanic Garden are likely to produce in December next on a fair average calculation, about 300 lb. weight of the seed.

I have the honor to be, Sir, Your most obedient Servant,

(Signed) J. G. LEAR.
Acting Superintendent.

The Rt. Hon'ble J. A. STEWART MACKENZIE, Governor of Ceylon, &c., &c., &c.
Royal Botanic Garden, Peradenia, June 21st 1839.

Sir,—I have the honor to acknowledge the receipt of Your Excellency's letter of the 17th instant, accompanying which was a packet of flower seeds I have disposed of in the manner Your Excellency was pleased to direct, and I beg leave to say that I will give my most particular attention to the "2 boxes of plants" received from Calcutta (of which I herewith enclose "the original list") and report their condition immediately on their arrival at Peradenia; in compliance also with Your Excellency's wish, I will prepare a report of my latest proceedings in the Royal Botanic Garden, and forward it in due course for Your Excellency's information.

I have the Honor to be, Sir, Your Excellency's most humble and obedient Servant,
J. G. LEAR.

LIST OF PLANTS CONTAINED IN TWO GLAZED CHESTS BY THE HON'BLE MRS. STEWART MACKENZIE, &C.

CHEST No. 1.

- 1 1 Heliotropium peruvianum
- 2 1 Bignonia amoena
- 3 1 Spathodea uncinata, Spr. A charming S. American plant
- 4 1 Guaiacum officinale
- 5 1 Heimia myrtifolia, South America
- 6 1 Curcuma roscoe, Wall
- 7 1 Hitchenia glauca, Wall
- 8 1 Melodinus monogynus, Row
- 9 1 Gastrochilus pulcherrima, Wall
- 10 1 Kæmpferia elegans, Wall
- 11 1 do roscoe, Wall
- 12 1 Burma Bamboo. The largest bamboo in the world
- 13 1 Strobilanthes sabiniana, Nees
- 14 1 do callosa, Nees
- 15 1 Petalidium bignoniaceum, Wall
- 16 1 Canna discolor, Lindl
- 17 1 Olea myrtifolia, Wall

CHEST No. 2.

- 18 1 Spermadictyon azureum, Wall
- 19 1 Mimosa sensitiva, S. Amer.
- 20 1 Magnolia sphenocarpa, Brown
- 21 1 Cinnamomum candatum, Wall
- 22 1 Gendarussa neesiana, Nees
- 23 1 Ficus elastica, Roxb., the Indiarubber tree
- 24 1 Memecylon capitellatum
- 25 1 Cynometra polyandra, Roxb.
- 26 1 Volkameria adorata, R.
- 27 1 Cryptophragmium venustum, Nees
- 28 1 Cryptostegia grandiflora, Brown

CHEST No. 2.—(contd.)

- 29 1 Hura crepitans, L.
- 30 1 Kayea floribunda, Wall
- 31 1 Cnestis monodelpha
- 32 1 Securidaca paniculata, R.
- 33 1 Butea superba, R.
- 34 1 Lagerströmia elegans, Wall

A. MALLAH, M. D.,
Superintendent.

Botanic Garden,
Calcutta the 14th Decr, 1838.

His Excellency the Rt. Hon'ble the Governor, &c., &c., &c.

Royal Botanic Garden, Peradenia, Jan. 28th, 1839.

Sir,—I have the honor to forward enclosed for Your Excellency's information, a report on the con-

dition of the plants contained in the two cases from Calcutta, which came safe to hand on the 26th instant, and a statement of my proceedings in the Royal Botanic Garden as requested by Your Excellency's letter of the 17th instant. In compliance also with former instructions from Your Excellency, I have the honor to forward a specimen of chocolate I have prepared during the last few days from fruit grown in the Royal Botanic Garden Peradenia. It is pure, but of course manufacturer being myself, unacquainted with the practical process. The system however has been followed as nearly as possible that I previously had the honor to lay before Your Excellency, extracted from works of great popularity, and I trust the result will receive Your Excellency's satisfaction.

I have the Honor to be, Sir, Your Excellency's most humble and obedient Servant,

J. G. LEAR.

Royal Botanic Garden, Peradenia, 28th, Jany. 1839.

Chest No. 2 was a little broken, and the plants contained in it were more injured (from that cause) than those in No. 1.

J. G. LEAR,
Actg. Supdt.

Royal Botanic Garden, Peradenia, Jany. 28th, 1839.

For the information of His Excellency the Rt. Hon'ble the GOVERNOR,

Since I had last the honor of reporting the condition of the Royal Botanic Garden, and stating the alterations I had in view, the progress I have

made I am sorry falls something short of my calculation. It has nevertheless engaged the bulk of my most constant and laborious attention, and I hope formed the basis of some permanent improvement, and a resource from whence some ultimate good may be derived; nothing but a prospect of which has urged me to exertion, nor does anything else at present promise to reward me. It would be very difficult, if not impossible, for me to explain in the first place, the great hardship I have had to surmount, in endeavouring to introduce a system of labour amongst the people of the Establishment, which has been one great drawback to all my proceedings. I mention the circumstance, because it could not reasonably be supposed a fact, that where the best experience has been centered and encouragement given to establish the opposite, there could have existed even amongst the labourers, such a total disregard to order, or so much ignorance of common works. My endeavours to effect a change for the better have not been unattended with success to a certain degree, and I look forward with much satisfaction to the prospect of having removed an obstacle so troublesome and discouraging.

The work I have performed has been the enlargement of the Kitchen Garden, which has been all trenched, and now consists of about 3 acres, but the want of a regular supply of seeds, the necessity of which I have before stated, will render a portion of it still unnecessary, and I must here beg to mention that it is behind the reach of any individual to ascertain here the proper or best times for the different kinds of English vegetables, unless he has an opportunity of trying them at all: one season is not sufficient, but one year would be. The few seeds I have at different times received have as often varied in their produce, better or worse as the time may be (or perhaps the condition of the seeds), but from the above course I shall not be able to gather any satisfactory information. The establishment of a nursery for useful plants has received much of my attention, about 4 acres (which will require enlarging) have been trenched for the purpose, and is now nearly stocked. It contains at present (68,000) sixty-eight thousand seedling coffee plants taken up from the jungle and planted in beds, most of which will be fit to transplant finally in May next, 18,000 mulberry plants propagated from cuttings since last October, and will be fit for transplanting in March if the weather permits in any part of the island, 2000 seedlings of nutmegs and cloves, and a small quantity of many other kinds of fruit trees. 4 parabs of coffee seed are sown procured from Hoova to ascertain if a change of country will prove of any benefit to them, 9000 seeds of cacao, to which quantity I am daily adding. The good which will result from a nursery well attended to, and the accommodation it will be of to all planters who can avail themselves of such a resource, is too evident to require words to support it. Many gentlemen have expressed themselves to me in high terms of the opinion which they entertained of it, several have spoken to me on the subject of supplying them with plants, and one official application is now filed in the office for (100,000) one hundred thousand coffee plants at the rate per thousand to be fixed hereafter which I have calculated should be about 15s. A proper arrangement in the Botanical department of the Royal Botanic Garden has also occupied a great portion of my best attention, but the weather for the last few months having been so unexpectedly dry, put a check to the transplanting, which I had deemed expedient, and must now remain until the next rains, finding it quite impossible at other seasons to perform such work with any degree of success. I have notwithstanding endeavoured to put the borders in

fit order for the alteration, and also the roads accessible to them; for which purpose I have laid upwards of (12,000) twelve thousand feet of turf and used 400 loads of gravel, all procured by the strength of the Establishment. I have also felled many of the superfluous plants and trees with which the borders were thickly studded, repaired many of the channels for the conveyance of water, and am now engaged in forming suitable reservoirs for its reception in various parts of the premises.

J. G. LEAR,
Actg. Superintendent.

Memorial to His Excellency the Rt. Hon'ble the GOVERNOR.

Sir,—It having pleased Your Excellency to bestow upon me the honor of filling the situation as Acting Superintendent of the Royal Botanic Gardens, Peradenia, I have since ever felt it a pleasing duty to observe from time to time, as they occurred to me, such circumstances as had a tendency to advance the object and interest of that Establishment, for the purpose of laying the substance of them before Your Excellency to receive the benefit of that wise adaptation which characterizes the policy of your Government; confirmed in the opinion that such a course of proceeding, if honor'd by your notice, will terminate ultimately in some good to the Colony. The short experience however that I have had in the above situation, and exposed at the same time to many disadvantages, rendered it impossible for me to have completed the series of observations it was my purpose to do; yet, as the statement of many already known particulars may be unwisely delayed my presumption on this occasion I trust will, in consequence, bear no relation to the character of unwarrantable interposition; it is not my purpose to endeavour by supposition or unguarded statement to undervalue the existence of an Establishment of the above nature, even upon a much less respectable foundation than our present one; nor would I dare for a moment to suppose that Your Excellency is not perfectly aware that one of a more extensive and influential character would diffuse more generally through the island much required and proportionable benefits. My object is principally to show that under the existence of present arrangements, which govern and confine the exertions of our Establishment much good is lost to the community, which a little outlay and interference on the part of Government might easily secure, and that too little importance is attached to it generally, owing to the extensive knowledge of the fact, that means are too limited for much good to be produced or for many to feel its effects. There is but little at present upon which to build a safe calculation for those who are anxious to benefit by its example, its produce or discoveries, and that this may be remedied I most humbly suggest to Your Excellency, that the portion of land within the limits of the Botanic Garden, planted with coffee, and now occupied on lease by H. Wright Esq. be taken over to Government, that gentleman being desirous, I believe, to adopt such terms. That this would be an advantage to Government I farther beg to mention; it would at once make the Botanic Garden more private, give greater security to its products, and more ample means to accommodate all demands that may be made upon it. The rent at present paid by Mr. Wright is £63 per annum, its produce last year was worth a little upwards of that sum, the jack and coconut trees upon it, rent for £20 per annum, making receipts amount say to £84, which I think is within the actual sum; labour costs perhaps £30 to keep it a little cleared, which would make a loss of £9 per annum at present, and under good care, after years may be fairly calculated to

multiply this loss into some gain. By the above land being in other than Government hands (waving all other considerations) has the following very prominent and important objections. The coolies employed upon it have access to the Roads through the Botanic Garden, at all hours of the day, they become acquainted with the state and position of every thing in the Garden, and the which becomes widely circulated by these being often changed, and in consequence the Botanic Gardens are exposed to very numerous chances of depredation, and many times to my knowledge and regret they have been taken advantage of; in addition to this, the rent of the coconut and jack trees is annually sold by auction to one individual, who again lets the same off in lots, to suit the circumstances of the applicants, and the number of sub-renters exceed that of the coolies employed; these sub-renters sell their rents when it is inconvenient to hold them longer, or they employ other people to gather in their produce, and thus the Botanic Garden is made an open and continual thoroughfare to an unlimited number of natives, and frequently to known bad characters, whose traffic and depredations occasion the labour of one cooly at least from me to put in order. It may be here I hope with good prudence also observed, that the advantages to this flourishing Colony of an extensive nursery combined with an Horticultural department well provided with seeds for experiments, are so great and promising, that security, space and encouragement would be well bestowed upon it. In support of this opinion I beg to offer the following:—I have received from individuals who have known that I was an advocate for the introduction of such a practice, applications for coffee plants alone, to the amount of nearly 200,000, and at 1s per 1000 would produce £150—three times that quantity I may venture to say would be disposed of in a short time, were I empowered to publish, that I could supply them; but to some of the above applicants I was obliged to return an answer doubtful of the probability of being able to serve them at the periods required. Several verbal applications have also been made to me for coffee, nutmegs, cloves, chocolate, cardamoms, &c. Some I could not encourage from the above reason to be officially given. Should it please Your Excellency to give encouragement to this important department, I should here again most humbly suggest that the Superintendent be allowed to employ at fit seasons for the work, such a quantity of labour as would be sufficient to accomplish it in due time, and discharge them when their labour became unprofitable; this involves a very important consideration, for if such liberty cannot be exercised, the result must inevitably be dissatisfactory; however, I will not presume to enlarge upon this subject here, being sensible that Your Excellency is too well acquainted with the principles of nursery business to require it, particularly as relative to it in a Colony, where every-day experience shows, that the above attention is more necessary than in countries where seasons can be more firmly relied upon. A nursery should be at least 10 acres in extent and be enlarged as occasion served, to keep up a stock equal to the demands upon it. The expense of 12 coolies calculated to be employed constantly would manage it, but the strength equal to it should be employed at the most urgent and necessary seasons.

The best season is now approaching to form a nursery, and to the extent above given I am prepared with young plants to stock it. Should Your Excellency therefore be pleased to favour the opinions I have here ventured to state, and direct that they be acted upon, every command from Your Excellency respecting them shall have my most constant strenuous attention!

I have the Honor to be, Sir, Your Excellency's most obedient and very humble Servant,

J. G. LEAR.

Nuwera Eliya, 6th, April 1838.

COCONUT CATERPILLAR BLIGHT.

(From a Coconut Planter.)

In reply to your paragraph, I know of no thoroughly effective remedy for the caterpillar blight on coconut trees. In the Batticaloa district smoking them out is resorted to by burning the rubbish and dry leaves under the trees or between the lines, but this works only a partial or temporary cure.

A FEW LAST WORDS ON CEYLON BY AN EX-GOVERNOR AFTER 4 YEARS' ABSENCE.

BOTANICAL GARDENS.

I must not omit noticing the improved condition of our Botanical Gardens, which redounds to the credit of Dr. Trimen and his assistants. The Peradeniya Gardens were always one of our show places: they are now more deserving of a visit than ever. The park sward is a model of what grass grounds should be; the nomenclature of the trees is simple and effective and gives all necessary information to the ordinary visitor; while the scientific botanist is always sure of a hearty welcome from the Director.

The Garden of Hakgala is now one of the most beautiful spots in Ceylon, and is worth a pilgrimage, and the Garden of tropical products at Henaratgoda is well kept and most valuable by its display of various products, some which are being cultivated and others may possibly be cultivated with advantage in the lowcountry. There is one disparaging remark which I am obliged to make in regard to this Garden, namely the protection afforded in it to thousands of flying-foxes. It is a cruel hardship to the native owners of fruit trees that these voracious bats should be protected, indeed encouraged, in a Government institution. It is impossible to calculate the loss caused by the damage of these creatures, which think nothing of a journey of 20 miles at night to rob some garden. I well remember the constant complaints which used to pour in to me at Kandy on the subject of a colony of these bats at Peradeniya Gardens. They have now been expelled, and a few coolies armed with guns would soon drive them on flight from this city of refuge at Henaratgoda. Once dispersed from their present stronghold, the natives will make short work of them, and the coolies will gladly join in a battue and convert them into curries.—W. H. GREGORY.

NOTES ON PRODUCE AND FINANCE.

A decrease of 40 per cent in the tea trade of China naturally alarms the Celestials, who contemplate reprisals on the cotton interests of India. An order has been placed from Canton for a thousand looms and other plant, at a total cost of near £85,000, and it is expected that by next winter the cotton industry will be in full swing in China.

In the dispute between the importers and brokers and the dealers the position arrived at is explained by the following letter from the hon. secretary of the London Wholesale Tea Dealers' Association:—"With reference to the resolution passed at the meeting of the trade on the 14th inst., respecting the delivery of tea, I have the pleasure to inform you that a

conference of importers, dealers, brokers, and warehouse proprietors was held yesterday, at which the principle of having tea ready for delivery before being sold was unanimously admitted, and the following clause in lieu of Condition 4 was recommended for adoption:—“4. All teas to be ready for delivery on the day of sale. The weight notes to be delivered within three working days from the day of sale, or the buyer to have the option of refusing to accept such lot or lots for which he cannot obtain the weight notes. Missing packages, if equal to bulk, and not more than five per cent., are exempted from this condition, and are to be taken by the buyer at the original price and prompt if tendered within fourteen days from date of contract. In case China teas should be required by the buyer to be inspected, a further allowance of two days, making five in all, to be allowed for the completion of the delivery of the weight notes.” The only difference between this condition and the one passed at the dealers’ meeting is the completion of the delivery of weight notes on the third instead of the second day, but as the tea will be weighed before being submitted for sale, it is thoroughly understood that delivery of a part of the tea when demanded will be given as soon after the sale as possible. Although some catalogues have been printed on the old terms for next week, it is also understood that this condition will apply to these catalogues also, and that after next week the printed conditions will be altered, and no teas will be sold or purchased except on the new conditions.”

Discussing the Revenue and Mr. Goschen’s surplus, the *Standard* says:—“There have been more brilliant surpluses in the history of the country, but it is quite possible for a man of first-class financial ability and courage to do much with three millions. How will Mr. Goschen dispose of it? Will he abolish the tea duty? If he does, he might almost as well put an end to the Customs service entirely, and make tobacco a monopoly, spirits and wine matters of Excise, and throw all ports open unwatched by a single exciseman.”

There have been a great many crimes of adulteration perpetrated in the name of coffee, and this is the latest: A substance purporting to be coffee has come under analysis in Germany, which, instead of being the genuine article, is a mixture of chemicals and other ingredients harmful to the human economy. The chemical analysis revealed the following constitution in percentages:—Crude proteins 17.90, fat 2.03, ash 2.27, woody fibre 10.33, caffeine 0.04, sugar 1.99, non-nitrogenous extracts 64.04, matter soluble in water 24.85. When this concoction was examined by means of the microscope, the presence of lupin seeds, the cells of the outer skin of some kind of grain which could not be definitely determined, together with tiny hairs which might have been derived from wheat, were observed. The caffeine, it will be noticed, occurs in about the same proportion as it exists in genuine coffee. The objectionable ingredient in this mixture is the lupin seeds: these contain a certain bitter principle, which is well-known to have a harmful effect upon the human system.—*H. and C. Mail*, April 3rd.

CEYLON TEA IN MELBOURNE.

(From a Melbourne Correspondent.)

As one should always hear *cons* as well as *pros*, I can scarcely help repeating, for what it is worth what the manager of the tea department in Jas. Service & Co.’s house here said to me yesterday:—

“We are getting sick of Ceylon teas; they go ‘off’ so soon; supplies coming down, getting weaker in flavor every season, which is not the case with Indians.”

I have heard nothing of the kind from any other tea men, and will find out whether this man’s opinion is considered of value. I trust not.

THE CHINA TEA TRADE.

‘O. M. P.’ writes as follows to the *North-China Daily News*, under the date 28th March:—

Dear Sir,—Mr. Clement Allen, in his last year’s Report to the Foreign Office on the Tea Trade at Hankow, quotes largely from a letter which had appeared in your columns, from one whom he styles ‘A Pessimist Merchant of Shanghai.’ The season’s prospects at there foreshadowed were gloomy and unfavourable but the bad results both to native middlemen and to foreign exporters have far exceeded the gloomiest anticipations. The losses in many instances are almost past belief, and as many sales reported from London lately show a droop of from 33 to 47 per cent. on prices realised for counterpart early in the season, the winding up of this season promises to beat the record of bad times. Many native middlemen who commenced last season with fair capital have become bankrupt.

The reasons are not far to seek. Encouraged by the profit of the previous year the teamen brought down a large crop of first crop tea, most of which had been prepared hastily in bad weather, and was consequently one of the vilest crops as regards quality that has ever been brought to market for foreign use. After the Russian buyers had first taken their pick in Hankow, and the continental exporters had taken their pick in London, the stuff left for the discriminating British public was almost nauseating. I have no hesitation in saying that more than three-fourths of the first crop was tainted with some unpleasant flavour or other that made it positively unpalatable, and some was actually half rotted from rain-damage before it had been fired for use. Nothing else could have been expected where there are no proper buildings for receiving the raw leaf, and where the cottager growers adopt a plan of drying the freshly picked leaf over smoking straw or over a green wood fire. It is one of the crying evils of China that wealth of the country is wasted by the neglect of the most ordinary care in preparing her splendid raw materials; and her produce is brought into disrepute through this neglect. The damage incurred by the want of buildings for housing the newly picked leaf last year caused a difference in values which would have covered the cost of such buildings many times over.

As usual after a heavy first crop the ‘second’ crop was poor, hungry, and flavourless, and in a month or two it lost all the little briskness which made it at all serviceable. The ‘third’ crop was unimportant, and of much the same character as the second.

We are promised a better crop this year; that is to say, proclamations have been issued by the native authorities in many of the producing districts prohibiting the use of anything except charcoal in the firing processes. If these proclamations are effective a grand step in the right direction will have been taken, as so much depends upon the material used for the firing, and most of the objectionable flavours will be eliminated. The high prices obtained for really fine teas last year are likely to induce early picking in more districts, but of course in the end the quality depends entirely on the state of the weather during the picking time, as no improvement is spoken of in the facilities for housing the incurred leaf.

There is one point, however, on which too much stress cannot be laid. The stock of China Congou in the London warehouses is very large, considering the reduced consumption, and almost all of it is worth considerably less than it costs to produce the very commonest descriptions in China. Until this quantity is reduced considerably by the cessation of shipments of similar qualities from China there is no possible hope of prices raising to a paying point for the producer, at any rate so long as the enormous export duties and inland taxes exist. The real tug has at last come on us, and it has become evident to all connected with the trade that the imposts on tea in China must be considerably reduced, if not altogether abolished, or the trade will be reduced to a minimum. The taste for tea is increasing yearly, but China cannot hold her own in the competition to supply the demand unless these crushing taxes are removed.

It is rumoured that only four steamers will load teas in Hankow for London this season. It would be better if none went there to load, and that steamers should be despatched from Shanghai on fixed dates with part cargoes only. This sounds retrogressive, but if the Chinese will not keep level with other producing countries either in quality of their teas or by reducing their tariff and giving a cheap article, we must look for retrogression, if not extinction. It is a sad comment on the trade that four steamers should be now considered enough, whereas fifteen were at one time nought too many.

There is very little doubt that as far as English buyers are concerned the business this year will be a dragging one, and much of the first crop teas will have to be held by the Chinese and brought down to Shanghai for sale. It would be a great boon to many tea men, if they were allowed to bring down their teas in bond and pay duty in Shanghai at the time of export. At present it necessitates obtaining an advance on which interest has to be paid, of 30 per cent to 50 per cent of the value of a good deal of the tea which comes to Shanghai for sale before it can be forwarded, and this prevents much tea being sent down which would otherwise find its way to this market. This would probably have the double effect of encouraging the use of the bonded system, as well as of bringing the tea trade back to Shanghai.

The stock of China Congou in London on 1st June next will be at least 30,000,000 pounds, or six months supply at the present rate of deliveries for England and the Continent.—*C. Mail.*

COFFEE IN NETHERLANDS INDIA.

The Rajah of Jembrana, in Bali, intends, it is said, to carry on coffee cultivation there as a Government enterprise. He has already sent a commissioner to Java to see how that branch of planting is managed there, and to engage labourers for his behoof.

The *Batavia Nieuwsblad* says that the Java coffee crop this year will fall so short as to give rise to serious financial difficulties with the Government. The paddy crop too looks unpromising, and the sugar yield is no better. A deficit in the Budget looks alarmingly near, but the diminished tax-bearing power of the impoverished people allows no hope of additional revenue.—*Straits Times* April 15th.

CEYLON UPCOUNTRY PLANTING REPORT.

HOPEFUL TIMES AND THE PROSPECTS OF THE PLANTER—SIR ARTHUR GORDON AND HIS ADMINISTRATION IN CEYLON—HIGH PRICES FOR CACAO—OPINION OF A VISITOR ON CEYLON CACAO—COFFEE DOING VERY WELL.

April 23rd.

The spirit of the times is very hopeful, and we hear on all hands that the prospects of the tea planters are good. Knowing ones who profess to have their finger upon the pulse of the tea industry don't hesitate to talk of "a boom" coming; and there are visions, more or less distinct, of the near advent of the "gilded youth" seeking investments in tea property, and insisting on playing sterling money, and that down. The Tea companies are doing us a lot of good among the moneyed class, is what we are told; and it only wants time to allow the knowledge of what handsome returns some of them give, to filter into the imaginations of home investors, and then—we will be all in clover. Even the V.A's, as your columns show, are turning hopeful, and it is pleasing to learn of the authority of those infallibles, that we

have all made a mistake in our estimates of young tea, but a very much greater one in understanding what it will do when old. It is a comfort that the bright vision is ahead and not behind us; and that some having already lived through the original blunder, they will find the latter more easily borne with, when their old tea gives more than they expected. But against all this, we have to place the rising exchange, sickness among our coolies, and the Governor's things to "hand us down," and keep us humble. As to exchange, although we may not benefit when it spurts up, somebody else does; the influenza epidemic helps the consumption of quinine, and makes, or at least tends to make, our bark more valuable; but the Governor and his despatches—how can they be estimated? Is Sir Arthur benefited in any way by his wrong-headedness, is the planter benefited, are the coolies benefited? I don't know what object His Excellency has set before him as his aim in life; but if it is the high one of an inscrutable providence, he has, in his action regarding our labour laws, surely attained it. His ways are past finding out. I suppose it would be too funny a thing for Sir Arthur to leave a colony over which he has ruled, in peace and love with all men, or even on decent terms with the majority. He has not done it in the past, and it is clear he is not going to make an exception with Ceylon.

The splendid prices which Cacao is fetching make a cacao garden in these days a veritable Eldorado, and the tree itself seems to be responding as if it wanted to live up to the good times. Where it has been at all well cared for, there is now a fair spring crop, and a luxuriance of blossom which speaks well for the coming autumn one. The other day the island was visited by one of the big continental chocolate makers, and he was strong in praise of our Caracoe variety and as vigorous in denouncing the Forastero. There are very many more difficulties to be overcome in the roasting and manipulating of the latter; and it never does produce the same delicate flavoured chocolate which can be made from the plumper bean of the Caracoe sort. The highest prices will always be got for the red kind, whereas the others have to meet the competition of the West Indian growers. A planter who has both kinds growing has come to the conclusion that the Forastero pays better. He made a careful experiment of the weight of beans got from an equal number of pods of the two varieties, and found that the Forastero took considerably less to make a cwt, than the Caracoe did. This extra weight more than counterbalanced the lower price which Forastero gets in London, and that taking the thing all round Forastero could be grown at a better profit than Caracoe. To establish this a good many more experiments would have to be made. Meanwhile it is settled beyond doubt, that in Ceylon's possession of the true Caracoe variety which has died out of the West Indies, we have one reason why our produce has a booming market, and prices at 112s: whereas West Indians are dull, and go down as low as 50s. No doubt we cure better, and generally take more pains, but a flat bean would never be cured into a plump one, and it is the round, red, fat one which the chocolate manufacturers desire, and for which they are prepared to pay.

What Coffee there is promises to do very well on this side. There have been some three blossoms, two of which at least have set well, and the other may do so in spite of the rain which fell while the flower was out. But there is a little bug hanging about, which one would rather be spared, as it is a factor which may upset calculations however carefully they may have been made.

PEPPERCORN.

IRRIGATION AND CULTIVATION.

KALAWEWA AND ITS WATER SUPPLY—RAILWAY EXTENSION TO THE NORTH—THE DANGER TO CEYLON OF CONNECTING IT BY RAIL WITH INDIA—IRRIGATION WORKS, AND EUROPEANS VS. NATIVE AGRICULTURISTS—THE PROPOSED ADDRESS TO SIR ARTHUR GORDON: IN WHAT HE HAS DESERVED WELL OF THE COLONY AND HIS FAULTS—VAIN VATICINATIONS REGARDING THE WEATHER—A FIERCE STORM—THE LINDULA VALLEY REVISITED—COFFEE AND CINCHONA—THE PATRIARCH'S LATEST THEORY—GREVILLEAS, BLUE GUMS, AND SAPUS—SAD RECOLLECTIONS.

NANUOYA, April 23rd.

If, in the abnormal drought of the early part of this year, a tank at this elevation became almost dry, it is scarcely a matter for wonder that Kalawewa should run out, considering the demands made on it. I see that Sir Wm. Gregory agrees in the opinion that a third stream ought to be diverted so as to fully supply this important tank. On hearing of the dried-up condition of the great North-Central Province tank from a party who had visited it about three weeks ago, I wrote to an authority with special means of information on the subject; and even after a delay which I regret, although it was largely due to indisposition, I now give the reply as interesting and important:—

"Water, like other matter, cannot be in two places at once; and if the water of Kalawewa has been let into the tanks it is meant to supply, it is naturally reduced in the store tank itself. In 1888 and again in 1889 the whole of the tanks fed by the Yodiela were filled twice in each year, which means two harvests where there was only one before. This has been an exceptionally dry year and the tank was reduced to a depth of seven feet. The Dambuluoya is now (April 12th) again running and the tank is rapidly filling, and the water has been let down to the tanks below. In ordinary years the present supply is amply sufficient for all the tank has at present to do. When the channel to the N.-W. Province is opened it will require an additional supply of water and additional height in the spill; nothing more."

You will see that my correspondent talks of an additional supply of water, as if that could be easily obtained, while, as you are aware, Mr. Wrightson's plan of the spill included an ultimate addition to its height of 5 feet. When that is effected and the tank is filled, it will be a truly grand lake. Let us hope that it will speedily be rendered more accessible than it now is. While I do not understand my well-informed and able correspondent to be opposed to an extension of railway facilities to the tank region, even should the effect be to increase more than ever the successful competition of South Indian with native-grown rice, he has taken a very grave view indeed of the danger to which Ceylon would expose itself by directly hastening what is probably inevitable, the junction of our island with the Indian continent by means of a railway across Adam's or rather Rama's Bridge, as the series of reefs in the dividing channel are called. The objections stated below are worthy of deep and serious consideration. There may be defects in our system of island government, but we may well pray to be preserved from absorption in the Indian Empire. Half our revenue would then be expended in what we now so much deprecate, an enhanced military contribution. Here are the views of an able and farseeing man:—

"Will you allow me to suggest to you some considerations which make me hesitate to anticipate un-mixed advantage to Ceylon from the construction of a railway bridge connecting us with India.

"It will no doubt render Colombo the port of Southern India, and that equally no doubt will be a very good thing for Colombo, the population and prosperity of which will be greatly increased. Whether the coun-

try through which the railway passes will be equally benefited by the mere transit of Indian goods through it is another question, but to some extent, at all events it will benefit also.

"This is the favourable aspect of the matter, but there is another way of looking at it. Anyone who has the slightest acquaintance with practical politics must perceive that when once the watery boundary between India and Ceylon has been abolished, and Colombo has become virtually an Indian port, the absorption of Ceylon by India is inevitable. There are many and excellent reasons why it ought not to be so absorbed, but as I have said before no practical politician can fail to see that plausible general views (called 'broad') and the force and weight of the stronger Power (which will desire the annexation) will prevail. It is just as clear as that the abolition of the import duty must follow the abolition of the grain tax. People may ask 'Why should it?' and give very good reasons why the import duty should continue nevertheless. We, who have any political instinct, hardly take the trouble to answer their arguments. We know the one must go with the other. And so, believe me, it is in this case. If once Ceylon becomes, geographically, only the most southern promontory of India, she must soon, if not immediately, become administratively a part of India, and that I think will be anything but a benefit to Ceylon. Not only does the Central Government of India take to itself a fixed percentage of all taxation raised by its local governments, but it without scruple helps itself over and above this to any more, the absolute necessity for the expenditure of which locally cannot be shown: The result is that all local public works are at a stand-still. A high Madras Civilian recently stated that last year after having pared down the expenditure of the Presidency to starvation point the Central Government helped itself to no less than seventeen lacs of Madras Revenue in addition to the regular fixed percentage. Under this régime Colombo might swell, but the rest of Ceylon would shrivel."

As the writer of the recent article advocating a scheme which I suggested through the *Observer* so long ago as 1841, you will, of course, give full consideration to these views adverse to the proposed connection. I consider them very weighty, although the comparison with the grain taxes somewhat fails. It is now a principle of free trade policy that if a local excise on a locally grown product is abolished, the import duties on the similar article must also disappear, as otherwise the latter would be protective. But there is no absolute principle which would necessitate the absorption of Ceylon by India, on the connection of the two countries by railway. The probabilities, however, amount almost to a principle.

I had somehow received the idea that when the lands under the Kantalay tank came to be disposed of a special despatch from the Secretary of State directed the local Government to give preference to the native Company which had been formed, over Europeans who might desire to purchase. In truth I largely shared the view, which I believe is very generally held, that, when means of irrigation are provided for lands, such lands will be sold by Government if not exclusively yet preferably to rice growers. To settle all doubt on the subject, I wrote to a Government officer able to give the true state of the case. His reply was:—

"You ask whether 'it was in deference to express orders from the Secretary of State that the lands under Kantalay were handed over to natives, application by Elphinstone and others being refused.'—So far as I am aware, there were no such orders. And I think you must be mistaken about applications from Elphinstone and others being refused. Christie certainly, and I am all but sure Elphinstone also, had land below Kantalay.

"You also ask whether if land were applied for under tanks to plant cotton or some similar purpose there would be any hesitation in granting it. When land under tanks is put up for sale, Government do not

ask who buys it, and the best practical answer I can give is that Mr. Pole Carew a few weeks ago bought several lots of land under one of the branches of the Walawe scheme, for, I believe, the cultivation of cotton and tobacco."

Again, in reply to a second letter of mine, my correspondent wrote:—

"You are substantially but not verbally right in your interpretation of what I wrote about land under tanks. You say that you are glad to hear that 'lands supplied by Government with irrigation water are open to all purchasers and for all purposes.' I think I said all lands put up for sale by auction would be so available. But in some cases, just as Government sell a planter a bit of land next his estate for extension, without auction, so they sell land needed for the extension of the village fields or practically in possession of the villagers through a long succession of chena permits. But this does not apply to large blocks of land newly supplied with water."

If, therefore, even in remote parts of the island, Indian rice should ever be able so to compete with the native-grown article as to render the production of the latter unprofitable, the irrigation works will facilitate other enterprises such as the cultivation of cotton, tobacco, palms &c., as also the watering of grass meadows for the feeding of cattle. This consideration should tell with Europeans in modifying their objections to liberal votes for irrigation votes, which after all, from the time of Sir Henry Ward until now, have not aggregated more than half a million sterling. I quite anticipate a very large and profitable growth of cotton and other products in of dry and arid portions of the island by means the irrigation.

NANUOYA, April 25.

I wrote yesterday that if such a morning as had then dawned did not mean fair weather human vaccination was vain. And vain it is! On the lower portion of this estate there was fierce thunder- and rain-storm which gave 2.40 inches of rain in 45 minutes, the total being 2.56. That was at 4,700 feet altitude in the valley of the Dimbulanda. At the upper bungalow, altitude 5,750 feet, the measurement this morning is only 1.28, pretty well, however, after all we have had. The thunder was terrific and the flashes of lightning vivid beyond description. While all this was going on up here, we were down at Lindula, where, although the storm was felt, it was in a modified degree. On our return journey the flooded and roaring rivers, yellow and even red with silt, dicated what had been going on amidst the mountain heights.

It was interesting, after the lapse in a couple of years, to traverse the once familiar "Lorne Road" and to look down on the pretty scene of mingled cultivation and extended buildings, town merging into estate bungalows and stores in the low-lying valley of Lindula. It must still be a prosperous place, for Jordan & Co.'s store is one of the most extensive and well stocked beyond the capital. *En route* we were struck with the quantity of coffee and cinchona which still exists, although gradually giving way to tea. Near Lindula we saw some of the first planted succirubras, perfect giants. The sight of them led our friend "the patriarch" to broach his theory, that the cinchona has not been and cannot be naturalized in Ceylon: that fresh seed should constantly be obtained from South America. On the other hand, the latest Nilairi report indicates the success of the fine hybrid, *C. magnifolia*. The *Grevillea robusta* trees along the roadside were sights to see, those belonging to Dessford and Lorne being in a blaze of brilliant comb-like orange-coloured blossom. For symmetrical growth those at Somerset excelled. The roadside along Lamliere was lined with young grevilleas of most luxuriant foliage, planted by Mr. Wright, I understood, from seed yielded by a few old trees at his bungalow. A row of these

trees, severely trimmed and standing up tall and straight, along the road to the store, was very striking. I regard this tree as, for ornament and use, one of the greatest acquisitions in arboriculture the colony has even made. From the pruned branches of those lining the road through Dessford and Lorne a very appreciable supply of good fuel is available. Then both the blue gums and the sapus, at the lower elevations and in shelter, showed grand growth. The "earns" thus grown are not our indigenous *Michelia nilagirica*, but *Michelia champac*, an introduced plant with much larger leaves. More beautiful trees than those along the roadside at Langdale could not be wished for, and many of these also were in blossom,—covered with the large fragrant flowers so conspicuous in Hindu poetry and legend. About 4,600 feet is evidently the zone for these splendid trees. At a thousand feet higher up, with us, they have merely, as a rule, struggled for existence. That and worse we found to be the condition of some "white toons" which we recollect as fresh and flourishing after being put out some half dozen years ago. Now we found them with bare tops. So that clearly 4,600 feet must be too high for the typical *Cedrela toona*, while the red flourishes equally in the Kotagala valley and in Nuwara Eliya. Altogether the drive through the once familiar scenes, now revisited, was pleasant and interesting, although the sight of Langdale, Lorne and other places called up sad recollections of so many "Old familiar faces"

vanished into the land of the hereafter.

A NEW COCONUT PRODUCT.

Paragraphs have been going the round of London and provincial journals concerning a new manufactured product of the coconut, so much the reverse of correct, and so calculated to leave a wrong impression as to the future development of the new industry, that it may be well to correct these errors.

The product to which we refer is what has been termed "coconut butter," a name which is incorrect, and is probably accountable for much of the ill repute into which it has fallen. Being regarded as a "butter," and produced at about half the market price of ordinary butter, those who have written on the subject raise a cry condemning it as a new adulterant of the dairy produce, and a rival of margarine. In the first place, it is not a butter in any sense of the word and is not at all likely to be employed as an adulterant by reason of its peculiar flavour and colour. It is in fact a vegetable lard, and as such it is intended to be used, and is so employed in German kitchens in all cooking processes. We are desirous of correcting the erroneous statements regarding this article, because we believe there is a great future for it in a way and in a direction which we will indicate further on. It is, moreover, worthy of notice as being one more product added to scores of others from the same remarkable tree—the coconut palm—regarding which the British public are but inadequately informed. The graceful form and bright hue of its golden fruit and feathery foliage are well enough known to most readers of illustrated botany and books on the East; but how few are acquainted with the numberless uses to which every fraction of its stem, leaves, and fruit are applied by the natives of Eastern countries! So numerous are its uses, such a blessing is the tree to the races of tropical countries, and so little is known of its original habitat, that it has been termed "a gift of the gods."

We think it necessary to remove the wrong impression created by allusion to this new article as an "adulterant," because we believe it will build up a future trade in the eastern and western worlds. Throughout India wherever Indian coolies are found as labourers, as is the case in the west Indies, the natives of that vast country employ in their culinary operations a large quantity of fat under the name of "ghee," answerin in colour and quality to our "lard." It is the product of

buffalo-milk, and in as much as Hindoos will not use any animal fat, and Mohammedans avoid the use of hog's lard, this ghee is the only article in use throughout India for culinary purposes, and being in such large demand it is by no means cheap when purchased in the bazzaars. Now, in the newly introduced coconut fat, misnamed butter, there is at once a better and a cheaper article for Hindoo and Mussulman use. Being a purely vegetable product, it is commended to the scrupulous Hindoo and the prejudiced Mohammedan, and cannot fail to come into extensive use throughout India, and when we say this we say a great deal, because we have to deal with a population of two hundred millions. If it can be produced by German chemists at Mannheim at half the cost of butter, after incurring the charges on importing the bulky raw material from the East, how much more economy may be studied by its manufacturers in localities where the coconut is produced in such lavish abundance? The production of the nut may be indefinitely extended on the poorest soil in both the East and West Indies, offering employment and profit in our own colonies and dependencies.—“Ceylon Advertiser.”

NEW INDUSTRIES IN JAMAICA.

It is not too early in the day to contemplate the good to result from the proposed Exhibition. All Exhibitions, commencing with the pioneer Exhibition held in London in 1851, have had as their motive and their result the development of the resources and trade, not only of the countries in which they were held, but also of the countries which participated in them. An Exhibition to be held in Jamaica will have great scope for the fulfilment of these objects; for this is a country not simply abounding with products that by the application of science may be rendered of great commercial value; but one in which there are for the most part products which the commercial world is just now eager to obtain, either as a raw material for manufacturing purposes, or for the new or improved manufactures to which they may be applied. At a meeting of the Committee for the United Kingdom, an account of which appeared in a recent *Gleaner*, it was pointed out that among the machines that should be sent out for exhibition should be cheap and easy ones for the extraction of oils by compression, and the preparation of fibres, as well as the extraction of fibres from the stems of ramie, plantain, banana, silk-grass, penguin, bowstring hemp, pineapple, dagger, curatoo, &c., all of which are already common to this island. This points in the direction where lies the materials of which the industry of the world is waiting to get possession. Other parts of the West Indies are equally as rich as Jamaica in these products, and the only question is, who shall be first, and who shall be the most enterprising in turning these things to account?

Jamaica has for a long time been talking about her fibrous products; but for over a quarter of a century she has done no better than talk, whilst one sister colony has already established an industry for Sisal hemp, worth £50 a ton in the English market; and another is seeking to do the same in respect to the Silk Grass, said to be worth even more than Sisal hemp. By Trinidad papers just to hand, we find that in the little island of Tobago, an adjunct to the Government of Trinidad, a determined effort is about to be made to turn the silk grass to account by preparing the fibre for market. The Government botanist had reported that “as a fibre product the plant ranks among the first of its class, and as a new culture I can recommend it with considerable confidence to the facilities for its growth and the certainty that it will thrive derived from the fact that it now covers large areas as a weed and is present in every part of the island to the exclusion of others of its order. On the strength of this and other scientific reports, a company was formed with a capital of £4,000 to work the enterprise. It will thus be seen that Tobago has gone ahead to do that which Jamaica has been talking about for these thirty years or more. Fibres, not from silk grass alone, but also from a dozen other plants, have been prepared and sent to various Exhibitions; but beyond making the exhibits, in which

our people have always felt great pride, there has never been any practical result. The samples have always been pronounced to be excellent; but beyond that enterprise has never gone; as if people were only content to know, or content to have the world acknowledge that Jamaica abounds in fibre producing plants that if turned to account might realize wealth for the country.

The Silk Grass (*Furcraea Cubensis*) is found in different parts of Jamaica, and there is hardly any part of the island where, if encouraged, it would not grow. It should be of interest to us to observe and carefully note what Tobago is doing, and especially note the class of machinery which she employs to bring about the success of the enterprise upon which she has entered. The great drawback hitherto has been to obtain suitable machinery. The surmounting of this difficulty is one of the benefits to result from our Exhibition to which we look forward. It will be the interest of inventors and manufacturers to send out on exhibition machines that may be applied to our wants, in which case, not silk grass only but many other fibre yielding plants as well, which are just now troublesome weeds, might be turned to account. The Dagger and the Penguin have been referred to. Just now they have been allowed to over-run hundreds, perhaps thousands of acres in parts of the country adapted to their growth. The only use to which they are applied is in making fences, for which Penguin is extensively employed, otherwise they are absolutely worthless and pre-occupy the land to the absolute exclusion of every other description of growth. A fibre is obtainable from both these plants from which fabrics of a delicate texture might be manufactured.

But when we speak of the Silk Grass, the Penguin and the Dagger, we mention but a limited number of the fibre-yielding plants that are indigenous to this country; and then, perhaps, not the readiest and most available. As a few minutes conversation with the intelligent Manager of the Hope Botanic Garden would soon disclose, there are numerous fibre-yielding plants known only to botanists abounding here, in addition to those that are generally known. Mr. Harris has himself been giving much attention to the subject. But we need not go beyond the Banana for the present. It has long ago been demonstrated that the fibre of the banana is applicable to rope making and other purposes. It has been tested and found acceptable by manufactures, but there has come in the usual question by which our people have so often been stumped: “How much of it can you supply?” It is feared that Jamaica never succeeds in supplying other than samples. And yet to be able to put a large quantity of banana fibre in the market should not be attended with any difficulty, seeing that we are now growing bananas by the million for exportation. Each plant, or sucker, of the banana produces but a single bunch of fruit, and when this comes to maturity the stem has to be cut down, for it never bears a second time; but in its place from four to, in favorable districts, seven young shoots spring up. Those who have studied the subject have demonstrated that the fibre is the more valuable part of the plant, and that if enterprise were fairly directed towards it, the fruit would become of entirely secondary value, and it would be worth while to cultivate bananas, not for the fruit, but for the fibre. But the fruit, which has proved such a valuable resource during the long depression of the sugar industry, adding thousands upon thousands of pounds to the income of the island, is all that is turned to account; and the millions of stems, rich in fibre, that have been cut down every season have only been used as manure for the young plants.

It is time that our people begin to think seriously of turning waste materials to account, and there is no waste material of greater promise than that which is obtainable from our fibre-yielding plants. If we are not up and doing, we shall find ourselves outstripped in the race by even little Tobago, 26 miles long and 6 or 7 miles broad, with a population little more than half of that of the city of Kingston.—*Jamaica Gleaner*.

THE RUBY MINES OF BURMA.

A good deal of renewed interest has naturally been created in Burma and its ruby mines, in consequence of the recent visit to Burma of Sir Lepel Griffin. A gentleman writing from Bombay gives an account of the mines, which is highly interesting at the present time:—The ruby mines, as at present defined, may be considered as limited to the four valleys of Mogok, Say Boo, Kathey, and Kyatpyen; and, although they cover a nominal extent of 50 square miles (ten by five), the well-defined areas where ruby mines are known to have been actually worked are included in a total space of less than five square miles. The remaining space, although not worked in the past, is, however, considered likely to prove not less prolific of rubies in the future than that part which has been already exploited by the natives. Although they might be further subdivided, there were two principal modes of native mining—one adapted to the plains and the other to the hillsides. In the former the byon, or ruby earth, lies at a depth of from 3 to 20 feet; and in the latter the operations of the natives have been restricted to the clay in the fissures of the rocks. Fortunately, these mining operations can be carried on to the most advantage at different seasons of the year, the dry season being the most favourable for working the byon in the plains, and the wet, when the water is more abundant, for acting on the lodes in the rocks. At the same time, it may be observed that working on the lodes can be carried on during the wet season with little or no interruption. Experience has shown that while common stones are abundant in the byon, the larger and more valuable have generally been discovered, under greater engineering difficulties, in the lodes. These have only been worked by the natives in the soft clay which fills up the fissures of the rocks, and one of the first suggestions made for the improved working of the mines was to establish a way, or working, through the rocks in proximity to some formerly productive fissure. Should a profitable lode be reached, it would be easy to sink the necessary shafts, or establish drifts. For these operations only the simplest appliances, in the shape of drills, jumpers, and dynamite work by hand labour, would be requisite. With sufficient water power, which is rarely deficient, compressed-air machinery and diamond drills can be used. In one important point the native workmen were extremely deficient and behind the time. They neither understood nor could they supply artificial ventilation, and a large number of mines have evidently been abandoned, not because they are exhausted, but because the miners were stopped by accumulations of carbonic acid or oxide gases.

In working the byon in the plain of the valleys, it is most essential that the supply of water should be copious, continuous, and well regulated. Under native management the supply was provided in open aqueducts, and these are, of course, antiquated, and will have to give place to wrought or cast-iron pipes. On the supply of water depends the substitution of true hydraulic mining for the crude systems hitherto in use among the Burmese. The success of the mining operations in the past has arisen from their simplicity, and, probably, it will not be very different in the future. In dealing with the byon in the valley, very likely no mode will work better, or prove more remunerative, than the total removal of the crust of earth covering the byon, and then carrying the byon itself to the washing-house; and this operation might be continued over successive plots, until every inch of ruby-bearing gravel had been extracted. This mode of working

the byon applies evidently to that which is nearest the surface. Much of the byon lies at a depth which can only be made accessible by regular mining operations; but it is desirable, from every point of view, that the productiveness of these mines should be made evident without any avoidable delay; and for that reason, if for no other, the simplest and most economical—in the sense of certainty of result, as well as cheapness of cost—procedure should find favour.—*E. Mail.*

SELF-COLONIZATION OF THE COCONUT PALM.

The question whether the coconut palm is capable of establishing itself on oceanic islands, or other shores for the matter of that, from seed cast ashore, was long doubted; and if the recent evidence collected by Prof. Moseley, Mr. H. O. Forbes, and Dr. Guppy, together with the general distribution of the palm, be not sufficient to convince the most sceptical person on this point, there is now absolutely incontrovertible evidence that it is capable of doing so, even under apparently very unfavourable conditions.

In the current volume of *Nature* (p. 276) Captain Wharton describes the newly-raised Falcon Island in the Pacific; and in the last part of the Proceedings of the Royal Geographical Society, Mr. J. J. Lister gives an account of the natural history of the island. From this interesting contribution to the sources of insular floras we learn that he found two young coconut palms, not in a very flourishing condition, it is true; but they were there, and had evidently obtained a footing unaided by man. There were also a grass, a leguminous plant, and a young candle-nut (Aleurites), on this new volcanic island—a very good start under the circumstances, and suggestive of what might happen in the course of centuries.

W. BOTTING HEMSLEY.

KOLA.

Our Paris correspondent telegraphs:—A rival to caffeine as a muscle-bracing and stimulating drug has been found in kola. Professor Hæckel, of Marseilles, admits the virtues of caffeine, but he says those of kola are greater. He used it in the food of members of an Alpine club, who performed mountaineering feats of an unusual kind without being tired. The colonel of the 160th Regiment at Perpignan, dosed by the Professor with kola, made the ascent of the Canigou Mountain near Perpignan to a height of 9,137 feet, and felt quite fresh after his climb, which lasted twelve hours. He only halted once, and for twenty minutes, and ate nothing. The 124th Regiment was able last July to accomplish a march of fifteen and a half hours from Laval to Rennes under similar conditions. They covered a distance of 72 kilomètres, and were able to go much further in the last hour. They walked at the rate of 3½ miles an hour. Kola is better than oats for giving mettle and staying-power to horses. Perhaps the fasting-men have got hold of alkaloid of kola, of which a very small quantity goes a long way.—*Daily News*, 10th April.

Mr. Thomas Christy, F. L. S., writing from 25, Lime-street, E. C., yesterday, says: "I notice in your today's issue a paragraph respecting a remarkable drug. As I have for the past ten or twelve years been principally concerned in advocating the use of this important nut (kola), will you permit me to say that I should be most happy to give to any applicants

particulars of the same? At first the supplies brought to this country did not exceed perhaps 1 cwt. per annum, but now it is imported in quantities varying from 1 to 5 tons per month for use as a substitute for tea and coffee, especially for those who suffer from indigestion. Should any of your readers feel interested in this nut, and have at their command low-lying damp land in the Colonies, such as would exist on the shores of Ceylon, I would strongly advise them to cultivate the kola, as it is one of the most promising products of the future."—*Daily News*, 11th April.

THE FOOCHOW TEA GUILD,

TO THE EDITOR OF THE "DAILY PRESS."

SIR,—On reading the weekly issue of the *Foochow Daily Echo* of the 29th ultimo, I notice the Editor says that the Tea Guild is shaky, that many of its members are proposing to dissolve the Association, and that the rules issued with the approval of the Foochow General Chamber of Commerce, which were unwisely recognized by Foreign tea buyers, have caused harm to the trade. The Editor also wishes to know why the interests of tea growers and buyers should be entirely placed at the mercy of this Association, and says its dissolution will undoubtedly do a great deal of good to the trade.

In order to explain more fully the organization of the Association I beg to say (1) that the Guild is not a trading concern, and its assets consist only of a few thousand dollars lodged in a bank of good standing, upon which interest is paid. Whatever expenses are incurred have to be met by the payments made under the by-laws. (2) I can confidently say, as to the proposal of dissolving the Association, which has worked very well, that the statement of the Editor of the *Echo* is nothing more than a guess. (3) As to the rules, I can state that previous to the formation of this Association many of those interested in the tea trade were well aware of the ways and doings of unscrupulous buyers, who purchased large quantities of tea, payment for which was dependent on the chances of good markets at home, as you play the game of heads I win and tails you lose. Some of them were also in the habit of taking advantage of the weakness of the tea hong and only paid for the tea purchased after long delay; say, the tea bought in 1885 was not paid for till the year 1886, and in one instance a very small, almost nil, dividend was paid out of the estate of the defaulter. I refrain from giving many more instances till I am contradicted. As the tea hong had to contend against rash speculators, they were compelled to consult some of the high principled tea buyers as to the best way of conducting the tea trade, so that the reckless trading of the unscrupulous speculators might be curtailed, and after much discussion they agreed to make rules for the guidance of the trade. Consequently the organization of the Association, with the approval of the Foochow General Chamber of Commerce, was established in 1885.

I may here add, for the information of the reader, that the Association places no restriction whatever upon the tea growers and Chinese buyers in the tea districts, the only relations it has being with the tea hong, so, there is no foundation for the statement that the tea growers, &c., were entirely placed at the mercy of this Association.

As to the prophecy regarding the dissolution of the Association, I hear nothing of that kind has been proposed at the Association since the return of the principal members from Canton some days ago.

It may be well to remark that though the rules were in force, yet the tea hong were in no better condition than before. The reason why I say so is that if an unscrupulous speculator buys and ships of large quantities of tea, and uses the money obtained upon the hypothecation of such tea in some other way, paying, nothing to the tea hong at the agreed time, as mentioned in the Rules for the conduct of the tea trade in Foochow, what guarantee have the sellers for the safety of their money? To which can only answer one. They have only the remedy of recoures to law

to stop the tea *in transitu*, and how is this to be effected? for the bills of lading are in the hands of the Bank which advances the money upon the tea. I dare say the tea hong have no cause of action in this matter, though they have a case against the unscrupulous speculator, but if the man has not a penny to pay, will not the loss fall upon the tea hong? There was a case of this kind some two years ago in Foochow.

I must now conclude, for I think what I have stated above will suffice for the present, and at the same time beg to apologize for the length of this letter.—Yours respectfully,
NO ADVOCATE.
Foochow, 3rd April, 1890.—*Hong Kong Daily Press*.

COFFEE IN BRAZIL.

Rio, 22nd February, 1890.

To the Editor:—Dear Sir,—It may be of interest to your numerous readers to have a report on the present position and future prospects of Brazilian coffee. In any case the subject should be fairly ventilated in the interests of all concerned. I therefore beg to submit to you the following simple figures and shall be glad, if in doing so, I can call for reply, for or against my figures. From good information received, I calculate that from the 1st March we may estimate the stock of coffee in the interior at 1,500,000 bags. I estimate receipts in Rio at 7,500 bags per day from 1st March to 30th June. This would leave us with about 600,000 bags to carry over to next crop. I estimate the 1890-1891 crop: Rio 3,000,000, Santos 3,500,000. The 1890-1891 crop may be expected early to market and both Rio and Santos coffees promise to be of good quality.—I am, dear sir, yours truly,
NEMO.
—*Rio News*.

DRINK ANTIDOTE.—A Russian physician announces his great success with subcutaneous injections of strychnia in the treatment of drunkenness. He says it is as rapid as it is infallible, producing a positive loathing for alcohol, the result being brought about immediately; the patient is completely and permanently cured of the habit in eight or ten days. Dissolve 1 grain of strychnia in 200 drops of water, and inject 5 drops every twenty-four hours.—*Burgoyne, Burbidges*.

HYOSCINE, which is taking the place to some extent of *hyoscyamine*, when injected at the dose of one milligramme (1/65th grain English) subcutaneously, says Dr. Maguan (*Société de Biologie*), produces calm and induces sleep in maniacs and sufferers from alcoholic delirium. By means of one-half milligramme of hyoscine (1/13th grain English) he arrested an attack of tic in a child, and quieted profuse sweating in a hysterical patient. Dr. Laoorde says that 1/10th of a milligramme of pure hyoscine (1/650th grain English) is sufficient to produce these effects.—*Ibid*.

DYNAMOS AND WIND POWER.—The use of wind power for producing the electric light possesses the recommendation that it is cheap, and engineers are beginning to introduce motors driven by the wind where practicable. Such a motor has been in unsuccessful operation for some time at the northernmost lighthouse at Cape de la Hogue, where a windmill drives two dynamos, supplying electrical energy, which is stored up in accumulators. The mill rests upon a timber framing, and transmits motion by means of a vertical shaft and two pairs of conical cogwheels to a horizontal shaft. Pulleys are fixed to the latter, which drive the dynamos by means of belting. The windmill works automatically both during light winds and gales. This point is looked upon by engineers as the most difficult problem of the whole arrangement, but success has been obtained by employing a spherical regulator. This regulator acts by friction upon a shaft closing and opening the apertures in wind wheel in such a manner that the surface exposed to the wind, according to its force, is enlarged or reduced, a principle employed in turbines. The two dynamos work alternately in accordance with the amount of energy stored in the accumulators. The dynamos are thrown in and out of gear automatically.—*Court Journal*.

PYRETHRUM (INSECT POWDER PLANT).

The following compilation of particulars respecting Pyrethrum, the insect-powder plant, will probably be interesting to those who know the value of *petites cultures* in piling up little profits.

During the long series of desultory campaigns kept up by the Russian Government in the Caucasus, and resulting in the annexation of the country, the military cantonments simply swarmed with fleas. Like Pharaoh's frogs, these insects were everywhere, but were not as easily kept at bay. The floors of some of the tents seemed to be alive with them, and the men were at their wits' end to get rid of the pests. They so effectually banished sleep, that whole companies would prefer to lie in the open and take their chance of weather; rather than share the tents with the fleas.

Some of the Tcherkess prisoners, who knew the ways of the country better than their invaders, at last let out the secret of a plant whose smell was fatal to the lively flea; this was the Pyrethrum roseum. It did not appear to be in commerce, but was gathered up the mountain slopes at an altitude of 6,000 to 8,000 ft., whenever wanted, hung up to dry, and rubbed to powder between the hands. However, before long, the collection of plants became a regular occupation among the shepherds, and a Russo-Armenian merchant named Yumtikoff bought all that was brought in, and manufactured the powder.

From that small beginning arose a very considerable industry, the export tax upon which is a valuable item in the revenue of the province.

It is not quite clear whether the success of *P. roseum* as an insecticide induced trials on other allied species, or whether the mountaineers of Dalmatia had already knowledge of the properties of a similar plant. But ere long Pyrethrum cinerariæ folium was largely cultivated in the Littorale, and so anxious were the growers to keep the monopoly in their own hands, that all the seed sent out for sale to agents of other countries was carefully baked to prevent its germination. In 1856, M. C. Willemot commenced the cultivation of Caucasian Pyrethrum on a large scale in France. His plants were examined by Duchartre, and, not being recognised as a slight variety of *P. roseum*, were called by him *P. Willemotii* Duch. This accounts for the two synonyms in vogue.

For ourselves, it will be handiest to call the two species Caucasian and Dalmatian Pyrethrum respectively. Willemot recommends a somewhat open, dry soil, well-drained, and not too clayey in character, the plant being very ready to die when germinating in too much humidity, and easily killed when mature by water-logging the nursery-bed with careless irrigation. The seed is best mixed with light sandy soil, sown on the surface of a well-prepared bed, and covered with a thin stratum of sandy mould. A light rolling after sowing is beneficial. The bed must not be allowed to dry out to the shallow depth of the seed. In about thirty days the young plants make their appearance, and as soon as large enough to be handled, are transplanted 6 inches apart on a well-prepared bed. Three months subsequently they are re-transplanted at double the former distance. The plants bloom in the spring of their second year. Thus far for the French practice. Here the greater heat of our climate, and a little careful management, may ensure flowering the first season. The best rule will be to treat the plant in about the same way as we are accustomed to treat *Asters*, *Zinnias*, and the like.

In California the cultivation of the Dalmatian plant is carried on by a settler from Dalmatia much in the same way as Mr. Willemot has directed. A fine, loose, open soil with a little old manure, form the nursery bed. The seed is mixed with sand, sown on the surface, and raked in to not more than half-an-inch in depth. Too much water will destroy the seed. Weeding and transplanting in damp weather, when about a month old, concludes his directions.

Of the two species, *P. roseum* is by far the more showy. Its flower is not at all unlike a rather poor

Aster, the rays varying from pinkish-white to deep blood-red. The leaf is cut like a Fern. *P. cinerariæ-folium* is white-flowered, and has a considerable resemblance to the *Lasioppermum*, or Cape white Camomile-weed, which covers outspans and roadsides, having a yellow disk and brilliant white rays, the underside of which is discoloured to a dull grey. The leaves are also Fern-like, but more coarsely divided than in the *P. roseum*.

In the manufacture of the powder the flower-heads must be gathered in fine weather, immediately on their opening, as that is the period when the essential-oil, on which its insecticide virtue depends, is most plentiful. They are then dried in the shade, where a draught of air can be secured. Exposure to the sun, to moisture, or to artificial heat, deteriorates the produce extremely. When quite dry they may be ground at once, or preserved in tin canisters till the whole harvest is ready for manipulation. The plants themselves are also cut to within 4 inches from the ground, and after drying are ground up. Of this inferior produce, one-third part by weight is added to the powder of the blossoms. There is no doubt that the Colonial snuff manufacturers could grind a better and more saleable article than could be prepared by any foreign appliances. Of course, a coffee-mill, finely set, will somehow grind the material, but as the effect of the powder depends to a certain extent on its degree of fineness, it would be a pity to lose the advantage to be got by the special work of the snuff-mill and graduated sieves.

It is not to be expected that Pyrethrum will be of any great use as an insecticide in agricultural operations. Mr. Willmot, zealous to promote the new industry, proposed to protect wheat and maize from weevil by mixing ten ounces of his powder with ten bushels of grain. The effect would be scarcely appreciable. With bisulphide of carbon readily applied and certain in action, there is little reason to try Pyrethrum.

It has been tried in the United States to destroy insects in gardens in various ways, e.g., in form of dry powder puffed over the plants, in a mixture with water, and in fumigation. In all cases there is so much loss of the volatile oil by free contact with the atmosphere that its use can scarcely be said to be economical on any but a very small scale. *Roses* and *Cinerarias* may be cleared of aphids or green-fly by its means, but even in these cases the plan is amateurish, and presents no advantages over the old methods with tobacco water and tobacco fumigation. Domestic use as a safeguard against the lively flea is probably the proper outlet for the sale of Pyrethrum.—P. MAC-OWAN, F.L.S., Cape Town Botanic Garden.—*Gardeners' Chronicle*.

ARABIAN COFFEE,

There is nowadays no question that *Coffea arabica* is of African origin. Its natural habitat seem to be the country of Gallas and Harar. The plant was introduced into Yemen at the date of the Abyssinian conquest, and the downfall of the Himyarite Empire, about a century before the era of the Hegira. The culture of *Coffea* rapidly spread in all the western parts of Arabia Felix—that is to say, in the regions subject to tropical rains.

The system of cultivation has not altered for centuries, and the plantations of *Coffea*-shrubs on horizontal terraces on the mountain sides are to-day still like those of which Niebühr wrote, more than a century ago. The natural slope of the ground is sometimes very steep, consequently the walls of rough stones which sustain the terraces are built up to a height of from 20 to 26 feet, which is equal to, or even more than, the width of the terrace itself. This arrangement ensures perfect drainage, which is very salutary for such plantations. The soil is carefully prepared, and almost always shaded by large trees (*Ficus*, *Tamarindus*, *Ehretia*, *Dobers*, &c.), planted in a row. Many plantations are irrigated during the dry season

by means of reservoirs placed on a level with the highest terrace, and fed by the deviation of a spring or neighbouring stream. The plants are generally supplied from nurseries, and are obtained from seed. The seeds, before being used, receive a certain preparation which consists in the removal of the pulp, and the submission of the seeds to a slight drying in a layer of ashes. They are sown from October to December, in borders of good soil, enriched by cow or sheep dung. The seedlings are shaded from the extreme heat of the sun by a covering of boughs, and are watered at least once a week. At the end of six or seven weeks the young plants are carefully picked out and removed, wrapped in mats, to the prepared plateaux. The Coffee shrubs are planted in lines about 30 to 40 inches apart, they are watered once a fortnight, and the soil is manured when necessary. From two to four years must elapse before the shrubs begin to bear. In Haraz, some growers consider that plants obtained from natural seed-plots are more vigorous than those germinating from seeds submitted to the process above described.

The natural seed-plot is managed thus:—Many of the berries, when fully ripe, are attacked by birds, which eat the fleshy part of the pericarp (the pulp). The stone covering the seeds is thus laid bare, becomes detached from the plant, and falls to the ground. The cultivator examines the plantations every day, and hastens to lightly cover over these seeds on the place where they have fallen. They do not germinate for two or three months, but the young plants are said to grow to a height of from 12 to 15 inches in the first year, and to continue to develop rapidly. It is known that the pulpy portions of the fruits, dried in the sun and pounded, constitute a material used for the preparation of a stimulating beverage, possessing analogous properties to an infusion of tea. This warm draught has a very pleasant flavour when it is properly prepared. Scented with ginger or some other spice it is, with "Qât" (leaves of *Oatha edulis*), a favourite stimulant with the Arabs of Yemen, who do not use Coffee, as do the Turks and Europeans. Everywhere, in the sandy solitudes of Tehâma as well as on the steep summits in the Gebeli district, is raised the "Mikaye;" this is a hut made of branches, or a shanty of rough stones, often far away from any populated centre, where is sold, in default of any more substantial fare, the decoction of gische, known as "gafal," which is always to be had fresh, from earthen jars with long necks and large rounded bases.

The fruits of the Coffee trees, dried in the sun, arrive from the interior in their natural condition, in bags of matting. In the centres of exportation, the most important of which is the port of Hodeidah, the gafal is submitted to a process which is intended to separate the seed from the pulp. The operation is conducted by means of millstones moved by hand, which is very fatiguing work, and must necessarily be replaced by perfected machinery as soon as ever hand labour becomes dear. For some time past, mortars of English manufacture have been used at Aden. The material thus pounded is estimated to consist of 50 per cent. of the seeds proper, 35 per cent. of pounded pulp, 12½ per cent. of powder yielded by the stones, and 12½ per cent. of waste produce. The commercial value of the prepared seed is at the quay of Hodeidah from about £7 to £8 for 220 lb.—Translated from "Voyage au Yemen," by A. Deflers.—*Gardeners' Chronicle*.

PLANTING IN NORTH BORNEO.

Yesterday, I accompanied Mr. Resident Davies to the Hakka settlement, which was opened in 1883, about three miles to the north of Kudat. This is the only surviving evidence of the large sums of money spent in 1882 and 1883 on Chinese immigration. I was then stationed at Kudat, and it fell to my duty to superintend the clearing of the jungle, and to mark out the allotments of land given to some ninety-six Chinese—men, women, and children who were sent down by Sir Walter Medhurst, from Hongkong. The first care of

these settlers was to grow a crop of vegetables, and when I left Kudat in September, 1883, the Kudat residents were already supplied with fresh vegetables from the Hakka settlement. Some Liberian coffee and tea plants were obtained from the Silam-gardens, and the coffee soon showed that the situation was suited to its growth. Pressed by Mr. Resident Davies, the Chinese planted more coffee, and yesterday I was much struck with the appearance of the trees. The few trees, about fifty, planted in 1883, are magnificent. Then follow a few hundreds planted about 1887, from seed obtained from the older trees, and now the planting of coffee appears to be in favour with all the Chinese settlers, old and new. The large new clearings near Kudat—about 100 acres—are carefully planted with Liberian coffee, at about eight feet apart, while between the rows an interim crop of bananas, or pineapple, or vegetables, is planted to supply the settler with present means of subsistence. On our way we passed through the Victorian Coffee Estate, opened by Mr. Christian in 1886, and noted with satisfaction the heavy crops and general blossom on the trees. This estate is about to be handed over to a company now being formed by Mr. T. W. Richardson, of Swatow, who has obtained a gift of land—1,500 acres—from the Government, and a promise of 3,500 acres, at one dollar per acre, for a coffee plantation. The new company will start with every prospect of success. I never saw Liberian coffee thrive in Ceylon, as it does here, and the price of coffee is likely to be high for years; I expect the Government will derive great benefit from this production, which is one that both Chinese, Natives, or Europeans can take up in small or large quantities, and, as I learn from Mr. Davies, that Chinese settlers are coming down by each steamer, and that they already number nearly 1,000, I am led to believe that coffee-planting near Kudat will be prosecuted on a large scale, and will hereafter afford means of living to a large immigrant population: The Chinese can only be convinced by success, as Mr. Davies remarked; they have been selling a little crop for some years; and have found by experience that coffee yields a most profitable return, and they want more of it. H. W.

March 2nd, 1890

MAURITIUS.

Port-Louis, April 9th.

SUGAR: THE WEATHER AND THE CROP.—The plantation have been well watered by rain during the month, and vegetation is exuberant throughout the island. The season for cyclones having passed for the present year, it is probable that the production will nearly reach that of the last two years.

VANILLA.—Transactions have been very limited. We have to quote the sale of a few small lots at R22 to R23 per kilo for best quality, above 6 inches. A lot of about 150 kilos was offered for sale last week and withdrawn at R15.50 per kilo, (including vanilloes. As we mention in our last the outturn of the present crop will not exceed 12,000.

ALOE FIBRE.—The market is dull and we have no important sales to record. Prices are therefore nominal from R360 to R370 per ton for 1st quality and R330 to 340 for second quality.—*Merchants and Planters Gazette*, April 10th.

DR. VOELCKER, accompanied by Mr. W. B. Wishart, President of the Cawnpore Chamber of Commerce, has been making a short tour through the indigo districts visiting the leading concerns in Tirhoot and Chumparum.—*Indian Planters' Gazette*.

"**KEW BULLETIN.**"—The last number of the *Kew Bulletin* is devoted to a list of seeds of hardy herbat ceous plants, shrubs, and trees which may be had by way of exchange from the Royal Gardens at Kew. The list occupies no fewer than thirty-three pages in double columns.—*Gardeners' Chronicle*, March, 8th.

THE DECLINE OF THE TEA TRADE.

NATIVE OPINION.

The depression in the tea trade reached the lowest depth yet known in 1889, when the losses to Chinese tea merchants amounted to over Tls. 5,000,000. Such a depression inclines many to doubt if a revival is still possible. The native banks have not suffered yet to any great extent by the losses of the teamen, as the latter had not borrowed to any great extent from them, and therefore underwent these heavy losses without involving the banks. The banks, however, while congratulating themselves on having come out of it so well last year, are this year very chary of making advances for the tea season. By 15th March 1889, they had lent here about Tls. 1,000,000, and on 15th March 1890, so far as we can learn, they have is yet advanced next to nothing. The tea-season is likely to commence later than usual, partly owing to this cause and partly to the fact that many Chinese firms, warned by the number of failures last year, have ceased to do business in such an uncertain article as tea has lately proved itself.

At Hankow the principal Chinese tea firm is the old established Ts'ien Shên An, next to which in the magnitude of the business done came the Oh'un Hwa Siang and the I T'ai Oh'ang. The second-mentioned has, we hear, borrowed little or nothing as yet from the Hankow native banks, the first-named is said to have obtained from them advances of a considerable amount after China New Year, and the last-named, the I T'ai Ch'ang, is said to have been accommodated to the extent of over Tls. 100,000, intending to carry on the campaign this season with still greater energy than the preceding one. A new firm, the How Shêng Siang has started. The remaining old native houses seem to be in a manner paralysed by the bad results of last year's operations.

Forty-two new Canton firms and two new Shansi ones have started, with perhaps others, and in the tea growing districts of Yang-low tung and Ch'ang show-kai in the hills, the agents who purchase tea from the growers had already made their arrangements for renting premises before China New Year, and so we may expect that although the tea season may begin later, the business with those two districts will be as brisk as ever, though the tea growing districts of Ch'ang-yang, T'ung-shang and Han-ning will miss some agents who went there last year.

To come to foreign honges, we hear that Yuan Fang will do nothing in tea this year. It is also rumoured that four others, Li Ki, Ts'ien T'ai, Hwa Ki, and King Ki will do nothing.

The Russian black tea exporters were last year hampered in their operations by a dread of Indian tea being used to adulterate the Chinese leaf. Several Shansi firms of hundreds of years' standing, who enjoy the entire confidence of the Russians, nevertheless did a good business with them.

This dislike of the Russians for Indian tea is encouraging in the face of the constant tirades to which we are treated by the European press on the supplanting of Chinese tea by Indian, which they assert to be advancing with such alarming rapidity. It confirms us in a suspicion that the principal recommendation of Indian tea is not its excellence, but its cheapness, which it owes to its freedom from export duty.

We have tasted Japanese tea, another rival of Chinese, though very different in quality from Indian, which is black, while Japanese is green. The cup we sampled was some brought to China from Japan, not intended for export to Europe or America. It was delicate and fragrant, but better to smell and look at than to drink; a smoky flavour was perceptible with the first mouthful, and the second pot made from the leaves was like water. The Japanese soil is thin and wanting in solid constituents, and its product delicate and ephemeral, and very different from Chinese Hyson.

At Shaohing a friend sent us some *ming-t's'ien* Pingsauy tea. *Ming-t's'ien* is so called because gathered before the Ch'ing Ming anniversary, and thus still

earlier than Hyson, which means 'before the rains.' It was excellent both in colour and flavour, but only stood two infusions.

The bonze Ka Tao, in charge of the Wan Nien Sze Monastery on Tientaishan, once gave me some tea called *Yanwu*, 'Mistcloud,' because it grew on the top of the Tien Tai mountain, where there are almost always clouds resting. It gave an excellent pot of tea at the tenth infusion of the same leaves. It is very doubtful if any tea can be grown outside of China which can do as much; but perhaps this is no recommendation with foreigners, who generally only require one infusion and hence can make even the weak Japanese leaf serve their purpose. Some even eat the leaves with the liquor.

In our own opinion, we repeat, the decline in the Chinese tea trade is due to no deterioration in the quality of Chinese which the Russians are right in considering as good as ever. It is simply due to the advantage which its rival the Indian tea enjoys in cheapness caused by the absence of export duty.

Against such an advantage we fear that the remedies proposed, to employ machinery and to supply a purer article, will avail very little. The only effectual remedy will be the reduction of export duty and *likiu* dues, if practicable.—*Shu Pao*, in *C. Mail*.

THE ADVANCE OF SCIENCE IN 20 YEARS.

Nature on the 20th Anniversary of its first issue, publishes the following concise summary of the progress of Science in that period:—

In the physical sciences, the enormous development of the atomic theory, and the establishment of a connection between the theories of electricity and light, are perhaps the two main achievements of the years we are considering. Methods of accomplishing the at first sight impossible task of measuring atomic magnitudes have been devised. Our own volumes contain some of the most interesting papers of Sir William Thomson on this subject, and the close agreement in the results attained by very different methods is sufficient proof that, if only approximations, they are approximations we may trust. The brilliant vortex atom theory of Sir William Thomson has not as yet achieved the position of a proved hypothesis, but has stimulated mathematical inquiry. A number of very powerful researches have added to our knowledge of a most difficult branch of mathematics, which may yet furnish the basis of a theory which shall deduce the nature of matter and the phenomena of radiation from a single group of assumptions.

The theory of gases has been extended in both directions. The able attempt of Van der Waals to bring both vapour and liquid within the grasp of a single theory is complimentary to the extension by Crookes, Hittorf, and Osborne Reynolds of our knowledge of phenomena which are best studied in gases of great tenuity.

The gradual expansion of thermodynamics, and in general of the domain of dynamics from molar to molecular phenomena, has been carried on by Willard, Gibbs, J. J. Thomson and others, until, in many cases, theory seems to have outrun not only our present experimental powers, but almost any conceivable extension which they may hereafter undergo.

The pregnant suggestion of Maxwell that light is an electro-magnetic phenomenon has borne good fruit. Gradually the theory is taking form and shape, and the epoch-making experiments of Hertz, together with the recent work of Lodge, J. J. Thomson and Glazebrook, furnish a complete proof of its fundamental hypotheses. The great development of the technical applications of electricity has stimulated the public interest in this science, and has necessitated a more detailed study of magnetism and of the laws of periodic currents. The telephone and the microphone have eclipsed the wonders of the telegraph, and furnish new means of wresting fresh secrets from Nature.

Science has become more than ever cosmopolitan, owing chiefly to the imperative necessity for an early agreement as to the values of various units for a com-

mon nomenclature, and for simultaneous observations in widely separated localities. International Conferences are the order of the day, and the new units which they have defined are based upon experiments by many first-rate observers in many lands, amongst whom the name of Lord Rayleigh stands second to none.

On the side of chemistry the periodic law of Mendeleeff has become established as a generalization of the first importance, and the extraordinary feat of foretelling the physical properties of an as yet undiscovered element has attracted to it the attention of the whole scientific world.

The once permanent gases are permanent no more. Duong and Petit's law has found a complement in the methods of Raoult. The old doctrine of valency is giving way to more elastic hypotheses. The extraordinary progress of organic chemistry, which originated in the work and influence of Liebig and the Giessen school, has continued at an accelerated rate. The practical value of even the most recondite investigations of pure science has again been exemplified by the enormous development of the coal-tar industry, and by the numerous syntheses of organic products which have added to the material resources of the community.

The increase of our knowledge of the sun by means of localized spectroscopic observation; the application of photography to astronomy, and more recently still the extension and generalization of the nebular hypothesis are perhaps the most remarkable developments of those branches of science which relate to astronomy. Stars which no human eye will ever see are now known to us as surely as those which are clearly visible. The efforts to reduce nebulae, comets, and stars under one common law, as various cases of the collision or aggregation of meteoritic swarms, and the striking investigations of Prof. Darwin on the effects of tidal action, and on the application of the laws of gases to a meteoritic plenum, give promise of a fuller knowledge of the birth and death of worlds.

In the biological sciences, the progress during the last twenty years has consisted chiefly in the firm establishment of the Darwinian doctrine, and the application of it and its subordinate conceptions in a variety of fields of investigation. The progress of experimental physiology has been marked by increasing exactitude in the application of physical methods to the study of the properties of living bodies, but it has not as yet benefited, as have other branches of biology, from the fecundating influence of Darwin's writings: hence there is no very prominent physiological discovery to be recorded. The generation of scientific men which is now coming to middle age has been brought up in familiarity with Mr. Darwin's teaching, and is not affected by anything like hostility or *a priori* antagonism to such views. The result is seen in the vast number of embryological researches (stimulated by the theory that the development of the individual is an epitome of the development of the race) which these twenty years have produced and in the daily increasing attention to that study of the organism as a living thing definitely related to its conditions which Darwin himself set on foot. The marine laboratories of Naples, Newport, Beaufort, and Plymouth, have come into existence (as in earlier years their fore-runners on the coast of France), and served to organize and facilitate the study of living plants and animals. The *Challenger* and other deep-sea exploring expeditions have sailed forth and returned with their booty, which has been described with a detail and precision unknown in former times. The precise methods of microscopic study by means of section-cutting—due originally to Stricker, of Vienna—have within these twenty years made the study of cell-structure and cell-activity an essential part of morphology as it had already become of physiology. These, and the frank adoption of the theory of descent, have swept away old ideas of classification and affinities, and have relegated the Ascidian "polyps" of old days to the group of Vertebrata, and the Sponges to the Coelenterates. The nucleus of the protoplasmic cell—which twenty years ago had fallen from the high position of importance accorded to it by Schwann—has, through the researches of Bütschli, Flemming, and Van Beneden

been reinstated, and is now shown to be the seat of all-important activities in connection with cell-division and the fertilization of the egg. The discovery, of the phenomena of karyokinesis and their relation to fertilization will be reckoned hereafter as one of the most, if not the most, important of the biological discoveries of the past twenty years.

Apart from Darwinism, the most remarkable development of biological studies during these "twice tedious year" is undoubtedly the sudden rise and gigantic progress of our knowledge of the Bacteria. Though the foundations were laid fifty years ago by Schwann and Henle, and great advances were made by Pasteur and by Lister just before our period, yet it is within this span that the microscope and precise methods of culture have been applied to the study of the "vibrions," or "microbes," and the so-called "bacteriology" established. We now know, through the labours of Toussaint, Chauveau, Pasteur, and Koch, of a number of diseases which are definitely caused by Bacteria. We also have learnt from Pasteur how to control the attack of some of these dangerous parasites. Within these twenty years the antiseptic surgery founded by Sir Joseph Lister has received its full measure of trial and confirmation, whilst his opportunities and those of his fellow-countrymen for making further discoveries of a like kind have been ignorantly destroyed by an Act of Parliament.

To particularize some of the more striking zoological discoveries which come within our twenty years, we may cite—the Dipnoous fish-like creature *Ceratodus* of the Queensland rivers, discovered by Kreff; the jumping wheel-animalcule *Pedalion*, of Hudson; the development and the anatomy of the archaic Arthropod *Peripatus* worked out by Moseley, Balfour, and Sedgwick; the Hydrocorallineæ of Moseley, an entirely new group of compound animals; the fresh-water jelly-fish *Limnocoelium* of the Regent's Park lily-tank; the Silurian scorpion of Gotland and Lanarkshire; the protozoon *Chlamydomyxa* discovered by Archer in the Irish bogs; the Odontornithes and the Diocerata of the American palæontologists; the intracellular digestion obtaining in animals higher than Protozoa, and the significance of the "diapedesis" of blood-corpuscles in inflammation, and the general theory of phagocytes due to Meeznikow; the establishment of the principle of degeneration as of equal generality with that of progressive development, by Anton Dohrn; the demonstration by Weismann and others that we have no right to mix our Darwinism with Lamarckism, since no one has been able to bring forward a single case of transmission of acquired characters. Perhaps the attempt to purify the Darwinian doctrine from Lamarckian assumption will hereafter be regarded—whether it be successful or not—as the most characteristic feature of biological movement at the end of our double decade. Its earlier portion was distinguished by the publication of some of Darwin's later works. Its greatest event was his death.

In botany, twenty years ago, the teaching in our Universities was practically sterile. In one of our earliest numbers, Prof. James Stewart defended with some vigour the propriety of intrusting botany to a lecturer at Cambridge who was also charged with the duty of lecturing on electricity and magnetism. It is startling to compare a past, in which botany was regarded as a subject which might be tackled on anywhere, with its present condition, in which there is scarcely a seat of learning in the three kingdoms which is not turning out serious work. The younger English school would be ungrateful if it did not acknowledge its debt to the eminent German teachers from whom it has derived so much in the tradition and method of investigation. Sachs and De Bary have left an indelible mark on our younger Professors. But it would be a mistake to suppose that English modern botany has simply derived from Germany. It has developed a character of its own, in which the indirect influence of Darwin's later work can be not indistinctly traced. There has been a gradual revolt in England, the ultimate consequences of which have still to be developed, against the too physical conception of the phenomena of plant life which has been prevalent on the Continent. Darwin, by his researches on insectivorous plants and plant movement

from a purely biological point of view, prepared the way for this; Gardiner followed with a masterly demonstration of the physical continuity of protoplasm in plant tissues. This has thrown a new light on the phenomena studied by Darwin, and we need not, therefore, be surprised that his son, F. Darwin, has started what is virtually a new conception of the process of growth, by showing that its controlling element is to be sought in the living protoplasm of the cell, rather than in the investing cell-wall. On the whole, English botanists have shown a marked disposition to see in the study of protoplasm the real key to the interpretation of the phenomena of plant life. The complete analogy between the processes of secretion in animals and vegetables, established by Gardiner, and the essential part played by ferments in vegetable nutrition, illustrated by Green, are examples of the results of this line of inquiry. To Germany we owe a flood of information as to the function of the cell-nucleus, which it is singular has met with general acceptance, but little detailed corroboration in this country.

In morphology a review would be ineffective which did not go somewhat deeply into detail. The splendid hypothesis of Schwendener, of the composite nature of lichens as a commensal union of Algae and Fungi, has gradually won its way into acceptance. In England there is little of the first rank which calls for note except the researches of Bower on the production of sexual organs on the leafy plant in ferns without the intervention of an intermediate generation.

In vegetable physiology there seems a pause; the purely physical line of inquiry, as already suggested, seems to have yielded its utmost. The more biological line of inquiry has only yet begun to yield a foretaste of the results which will undoubtedly ultimately flow from it.

Something must be added as to systematic and geographical botany. The "Genera Plantarum" of Bentham and Hooker, the work of a quarter of a century at Kew, affords a complete review of the higher vegetation of the world, and has been accepted generally as a standard authority. To Bentham also we owe the completion of the "Flora Australiensis," the first complete account of the flora of any great continent.

In geographical botany, perhaps the most interesting results have been the gradual elaboration of a theory as to the distribution of plants in Africa, and the botanical exploration of China, of the vegetable productions of which, twenty years ago, almost nothing was known.

In the classification of the lower plants, perhaps the most interesting result has been the happy observations of Lankester upon a coloured Bacterium, which enabled him to show that many forms previously believed to be distinct might be phases of the same life-history.

In geology probably the greatest advance has been in the application of the microscope to the investigation of rock structure, which has given rise to a really rational petrology. All except the coarser-grained rocks were only capable of being described in vague terms; with modern methods their crystalline constituents are determinable, however minute, and the conditions under which they were formed, can be inferred.—*Nature*.

A GEOLOGICAL SURVEY OF CEYLON.

The recent successful search for coal in the South of England has led an old Colonist at home who has read our recent deliverances on the above topic, to write to us begging that we will not allow the subject to drop. "Here," he says, "have we been frightening ourselves because of the rapidity with which our coal fields are becoming exhausted, while all the time, as now appears to be probable, we have under our feet in the Southern districts, and within practicable working depth, perhaps a further almost limitless supply. If this should prove to be the case, Macaulay's New Zealander may remain, at least for another decade of centuries or so. He will not be wanted to gaze upon the ruins of deserted London for a pretty long spell yet!"

Now we can, we think, with tolerable justification adopt our friend's view as to what may at least be future possibilities for Ceylon. We have never heard that it has been held by such geological experts as have visited Ceylon that its formations are altogether opposed to the possible existence of coal beds within a workable depth. We may even be possessed of oil bearing strata sufficient, and even more than sufficient, for all local wants. But whether that be the case or not, we can readily imagine many other sources from which our island wealth might be increased; and it does not do to limit, after what has been accomplished elsewhere, the rewards to follow attempts at discovery. There is another matter besides which might be accepted as a strong inducement to undertake a systematic Geological Survey. We are at present wholly ignorant of how our water-bearing strata are situated. We go to a vast expense to store thousands of acres of rain water, and lose a very large proportion of that water by evaporation under our burning sun. All the time that we are doing this, it is far from improbable that, deep down in the bowels of the earth, perhaps immediately under those giant tanks which are among the wonders of our Eastern world, there may exist vast reservoirs of pent-up waters which need but the touch of the magician's wand—in other words, the diamond drill—to pour upwards their inexhaustible volume to refresh our thirsty soil at our will. Such considerations as these are not necessarily wide of the mark. Wholly unexpected resources may be lying beneath our feet, and some at least of these might be revealed to us by an expert Geological Survey based upon the use of efficient drilling apparatus.

Ceylon has too often been referred to as being a country possessed of little or no natural wealth. Her soil is generally described as poor, and as needing wealth to be "lugged" from it by sheer dexterity and the exercise of almost superhuman patience; while as for minerals, except as regards a few miserable plumbago pits, such have no place in Ceylon! "It is a one-horse sort of place altogether, sir, I tell you," is too often the verdict. We do not admit the description to be deserved, but undoubtedly we should do all we can to render it so absurd in the minds of most men that no one, however prejudiced, would in the future attempt to repeat it. Now if mineral deposits were to be discovered in Ceylon, or subterranean waters obtained to irrigate our arid soil in the north and east, it is easy to see that every possible ground would be cut from under the feet of the London city gossip, who is oftentimes both ignorant himself and the cause of ignorance in others. A new era of development would set in for this colony were it but once proved that it is possessed of extensive and varied mineral resources. Such proof we should say is never likely to precede systematic investigation, but we can readily conceive its following upon such a course. We strongly counsel that the need, both of the men and of the machinery for undertaking it, should be pressed upon Sir Arthur Havelock. The cost, relatively speaking, would be but small, and there could not be a better adviser for Government in this matter than our recent visitor, Mr. Barrington Brown. In the one item of plumbago alone—the monopoly in supplying which Ceylon has, of late years been rapidly assuming—there is ample encouragement to go the expense of a Survey; for there can be no doubt whatever of its leading to the discovery of new and extended deposits of this valuable mineral, apart from gem-bearing strata and the possibility of coming on a

paying auriferous quartz reef. For very good and weighty reasons, therefore, let us have the Geological Survey at the earliest possible date.

FUEL.

Rules Regarding the Supply of Firewood to Tea Estates in the Western Province and Province of Sabaragamuwa are published in the *Gazette*. Proprietors or managers of tea estates desirous of obtaining a permit to cut firewood for estate use in Crown forests shall make written application to the Government Agent of the Province; and then follow no less than 29 rules with schedules and list of trees not to be used for fuel in any case.

TOBACCO INDUSTRY IN THE PHILIPPINES.

Since the abandonment by the Spanish Government of the tobacco monopoly in the Philippines in 1882 the trade has received a great stimulus by the investment of private capital, and the more equitable treatment of native cultivators. The trade is now almost wholly in the hands of a Spanish Company which with a capital of three millions sterling, owns the largest tobacco estates. It has in its employment 10,000 hands, and the annual production is 80,000,000 cigars, 400,000,000 cigarettes, and 5,000,000 lb. of cut tobacco. There are also in the islands six other Spanish companies, two German and several Chinese. The Government demand at present is a license tax of about £20 annually for manufacturing tobacco. During the period of the Government monopoly each unmarried native was bound to plant 4,000, and each married native 8,000 plants a year, the leaves being delivered to the Government officials at a fixed price about 50 per cent below what they fetch now. The gross revenue to the State from the monopoly was about £800,000 per annum. The best tobaccos are manufactured from the plants grown in the provinces of Cagayan and Isabella in Luzon, and amount annually to between 60,000 and 100,000 tons. All the tobacco is manufactured into cigars and cigarettes, and is classified in six grades according to the size and quality of the leaves. About 60,000 acres in the island are under tobacco cultivation. During the year 1889 the cigars exported from the islands amounted to 112,074,000 of which Spain took 26,715,000 and Great Britain and its dependencies 17,871,000.—*M. Mail*.

TEA IN FOOCHOW.

(From the *Daily Echo*.)

We understand that very few tea manufactories in the country are making any preparation for the coming season. Pakling is the only district where repairing and preparation is general, in the tea hong. We have been assured that more than half of last year's teamen will be laid up for want of means and credit.

Though on every side we hear nothing but bad prospects for the coming tea season, nevertheless the tea box makers seem to be already actively preparing different sizes of boxes; in fact during the week quite a number of ready-made boxes were to be seen in the streets. Mysterious Foochow!!!

SUBSIDY TO JAPANESE TEA EXPORTERS.

Some time ago a meeting of Japanese merchants interested in the export of tea was held in Tokyo, when it was decided that a Company should be formed with a capital of half a million *yen* for the purpose of endeavouring to develop the brick-tea trade with Russia. Originally it was proposed to assist the project by levying a tax of 2 *sen* per box upon all tea prepared for export to Europe and America—or, to speak more correctly, upon all tea over which the Tea Guilds exercise control. Against this proposal, however, strong opposition speedily manifested itself, the tea men justly claiming that to tax the trade already

established for the purpose of opening a new and precarious market, could not be called a wise policy. Long and earnest debates took place on the subject, the final discussion being attended by the Minister of State for Agriculture and Commerce and by other officials, in the capacity of audience. A resolution was then adopted to the effect that application should be made to the Government for a subsidy at the rate of sixty thousand *yen* per annum for five years. The Government, on being approached, refused to accede to the request in this form, inasmuch as it is obviously inexpedient to enter at present into engagements binding the Treasury for a term of years. There seems, however, to have been a strong disposition to assist the enterprise, for in the end the Treasury agreed that a sum of 200,000 *yen* should be deposited in the Bank of Japan by way of subsidy, there to be held to the credit of the Finance Bureau of the Agricultural and Commercial Department, and be drawn against, if necessary, by the tea men with the consent and approval of the Bureau. In consideration of this subsidy, the new Company agreed to be bound by a charter of very stringent character, providing that no alteration could be made in the business programme of the Company without the endorsement of the Agricultural and Commercial Department; that any change in the Company's constitution which might seem advantageous to the Minister of that Department, could be made at his instance and by his direction; that no such change could be made by the Company without the Minister's assent; that the Minister should appoint inspectors to supervise the Company's accounts; that the profit and loss statements should be submitted twice annually to the Department of Agriculture and Commerce, and that the Minister of the latter should, within certain limits, exercise the power of appointing the Manager and Directors of the Company. The Government, in short, while agreeing to assist the Company financially, retained for itself very thorough control of all the Company's affairs. It may well be supposed that this arrangement has evoked much comment. As yet the leading vernacular journals have not all spoken, but two or three newspapers of the second rank have condemned the Government in very emphatic terms, and one of our local English contemporaries goes so far as to dub the Company's procedure "a bare-faced attack on the funds of the nation," declaring that the only result of the affair will be to "put into the pockets of the few gentlemen who have engineered the scheme a good many of the dollars wrung from the impoverished peasantry." We are by no means so rash as to assert that these criticisms may not be justified. It strikes us, however, that to utter them without any knowledge of the Company's real purpose or programme, is at least premature. Our English contemporary is plainly under the impression that the object of the subsidy is to assist in renewing disastrous attempts to divert the export trade from foreign into Japanese hands. He says, indeed, that "there is no reason to suppose that the Japanese will be any more diligent in pressing the sale of tea than foreigners are already." So far as that question is concerned, we are entirely at one with our contemporary. We believe that the foreign merchant, accepting, as he does, all the risks of the trade, and conducting it with the greatest intelligence and enterprise, is the best possible agent Japan can have at present. This, however, is a general verdict. With regard to the tea trade in particular, we are persuaded that the present system of preparing the staple for export invites material reforms which will surely be effected one day or another. Whether the new Company contemplates attempting such reforms we do not know, and until fuller information is procurable, we refrain from discussion. One point, however, is worthy of note. The idea which we have formed by examining the meagre details thus far published, is that the Company conceives no project of interfering with the present course of the tea trade to America and Europe, its chief, if not unique, purpose being to promote the export of brick-tea to Russia. Looking at the returns for

1889, we find that the value of the brick-tea exported to Russia during that year was only 4,315 *yen*, the aggregate value of all other kinds sent to the same destination being 1,320 *yen*. In fact, the export of Japanese tea to Russia may be said to have no existence as yet. The tea men think, apparently, that this state of affairs might be greatly altered by a little enterprise and the outlay of some capital, especially when they observe that Chinese brick-tea, their principal competitor, is saddled with an export duty of over 12 per cent. They may be right or they may be wrong—the former we trust—in this hypothesis. For the moment we note only that their apparent purpose is, not to enter into competition with the present foreign exporters, but to open up a field which the latter have not yet thought worth exploiting. At the same time we cannot but express surprise that the Government has been persuaded to resume, even on so small a scale, a rôle which it was thought to have wisely abandoned in perpetuity. Very strong arguments must have been forthcoming to convince the Cabinet of the expediency of taking this step, and we await their statement with curiosity. —*Japan Weekly Mail*.

SINGAPORE.—Mr. Ridley has published a report on the damage inflicted on the Coco-nut Palms in Singapore by two beetles. The illustration which he gives shows more forcibly than words can do, the terrible extent of the mischief. One beetle is the *Oryctes rhinoceros*, recently figured in the *Gardeners' Chronicle*; the other is the red weevil, *Rhyncophorus ferrugineus*. In the case of the *Oryctes*, it is not the grub which is destructive, but the perfect insect which flies by night to a Palm and burrows into the heart of the terminal bud or cabbage, not unfrequently destroying the growing point and causing the death of the tree. The pest can be kept in check by diligent destruction by fire of the decaying foliage in which the grubs live, and of the dead trees. The beetles may be extracted with a dart fixed on the end of a wire probe. Unless, however, these operations are made compulsory on all the growers, there is no hope for the careful planter surrounded by others who are careless. The red weevil deposits its eggs into the base of the living leaves of the Palms, the eggs are hatched, and the grubs find plenty of food in the succulent foliage. Their extirpation is a more difficult matter than in the case of the preceding, but the same methods may be tried.—*Gardeners' Chronicle*:

NEW GUINEA PLANTS.—Through the favour of Baron von Mueller, we have received advance sheets containing the descriptions of the plants collected in the highlands of New Guinea by Sir William Macgregor. The vegetation of the alpine heights in the Tropics is naturally of extreme interest to botanists, and hardly less so to horticulturists, who may fairly look for at least some novelties, more particularly at the lower elevations. Higher up, the conditions of alpine vegetation, even in the Tropics, are so similar to those met with in temperate alpine or in arctic regions, that there is a very considerable degree of uniformity of type in the vegetation: thus on the mountains of New Guinea, Baron Sir Ferdinand v. Mueller tells us, may be found the Dandelion, *Taraxacum officinale*, *Aira cæspitosa*, *Festuca ovina*, *Lycopodium clavatum*, *L. Selago*, *Hymenophyllum*, *Tunbridgense*, *Aspidium aculeatum*, all plants common on our Scottish or Welsh hills and elsewhere in Britain. Several new *Rhododendrons* are described, in connection with which the Baron reminds travellers unable to collect specimens or seeds for exportation, that they might collect the pollen and send it home to be used for hybridising purposes. We should prefer to pack it in soft dry paper rather than in oil-silk, which would favour the development of mould. New *Epacrids*, some suitable for cultivation, are described, and a new *Gentian* of interesting character. The *Conifers* include *Phyllocladus hypophylla* and *Libocedrus Papua*. The latter is a particularly interesting discovery, the distribution of the genus in California, Chili, New Zealand, Central China, and now in New Guinea, being very remarkable.—*Ibid*.

PROSPECTS OF CHINA TEA.—Writing here on the decline of the China tea trade and its causes and on what may be done to assist its recovery, we write from an interested standpoint, while the *China Overland Trade Report* writing in Hongkong is a more disinterested spectator of the calamity, and its advice will thus, perhaps, engage more attention. It says on its latest issue:—The trade has become unprofitable for foreign merchants and the number of firms engaged in it is diminishing. For a few years they continued working without profits in hope of better times, but these have not come, and one after another is giving up the struggle. With the total abolition of export duty and *likin*, bright days would again dawn for the tea trade of China. The fact that it has maintained its ground so long, handicapped as it has been, shows how highly China tea is appreciated by consumers and how readily it would be taken were the price reduced by the amount now paid as taxation. No lesson of political economy is clearer than that export duties are inherently vicious. The question of protection or free trade may still be open to argument; the policy of giving bounties on exports also finds supporters; but to handicap the products of a country, especially when there are keen competitors in the field, is a self-evident mistake. To give up the duty would be a great sacrifice to the Chinese Government, who would lose a revenue of nearly five million taels; but that is bound to disappear in any case; the only question is whether it shall be allowed to dwindle away gradually until at length the trade is annihilated or whether it shall be sacrificed at once, and the trade be preserved.—*N. C. Herald*.

LINNEAN SOCIETY.—The Society met on March 6, Mr. Carruthers, F.R.S., President in the chair. Mr. S. Lithgow was admitted, and Messrs. J. Lane, E. R. Waite, and G. F. Elliott were elected Fellows of the Society. Mr. Thomas Christy exhibited a dried specimen of *Picramnia antidesma*, the plant from the bark of which medicine known as *Cascara amara* is believed to be prepared, and which is a useful alternative in diseases of the blood and skin. A paper was read by Mr. D. Morris on the production of seed in certain varieties of Sugar-cane, the *Saccharum officinarum*. It was pointed out that, although well known as a cultivated plant, the Sugar-cane had nowhere been found wild; nor had the seed (carvopsis) been figured or described; it being the generally received opinion that having been propagated entirely by slips or cuttings, it had lost the power of producing seed. Spikelets, however, received at Kew, had been carefully examined and the seed found which was now for the first time exhibited by Mr. Morris. He anticipated that by cross-fertilisation and selection of seedlings, the Sugar-cane might be greatly improved, and much importance was attached to the subject, as it opened up a new field of investigation in regard to Sugar-cane cultivation. Mr. J. G. Baker and Mr. Christy concurred. A paper was then read by Mr. Spencer Moore on "The true Nature of callus: Part I. The Vegetable Marrow and *Ballia callitricha*." It was shown that the callus of sieve-tubes of the Vegetable Marrow gives marked proteid reactions, and since it is dissolved in a peptonising fluid, there can be no doubt of it being a true proteid, and not a kind of a starchy mucilage, as is usually supposed. The "stoppers" of *Ballia* also yield proteid reactions; but as inasmuch as they resist gastric digestion, the substance cannot be a true proteid, and may, perhaps, be allied to lardacein. Mr. Moore maintained the view of Russow, Strassburger, and others, that callus is deposited upon the sieve, to be correct in the case of the Vegetable Marrow, since a peptonising fluid clears the sieve-plates, and leaves them in their pristine condition, which would not be the case if callus were formed by a swelling up of the sieves. A discussion followed, in which Dr. F. W. Oliver, Dr. D. H. Scott, Professor Reynolds Green, and Mr. George Murray took part.—*Gardeners' Chronicle*.

WHALES AND ELEPHANTS.—The weight of the great Greenland or right whale is said to be 100 tons, or 220,000 lb.—equal to that of 88 elephants or 440 bears. The whale-bone in such a whale may be taken at 3,360 lb., and the oil at from 140 to 170 tons. There are annually killed in Africa a minimum of 65,000 elephants, yielding a production of a quantity of raw ivory, the selling price of which is about £850,000.—*South of India Observer*, March 22nd.

CYLON TEA IN AMERICA.—We call attention to the letter of Mr. A. G. Stanton of Gow, Wilson & Stanton on this subject further on. Mr. Stanton tells us a good deal that is interesting, more especially with reference to the Establishment of the Ceylon-American Co. in New York, and we shall look forward with pleasure to his future letters. The prospect of our teas getting into the American market and catching the taste of the people is decidedly improving.

A GIANT FLOWER.—A contemporary says:—"The biggest flower in the world was recently discovered by Dr. Alexander Schadenberg. It was found on Mount Parag, one of the south-eastern Philippine islands. The native who accompanied Dr. Schadenberg called the flower *bolo*. The *bolo* in bloom is a five-petalled flower, nearly a yard in diameter, as large as a carriage wheel. A single flower weighed over 22lb. The five petals of the immense flower are oval and creamy white, and grow around a centre filled with countless long violet-hued stamens."—*Pioneer*.

ENGLISH VEGETABLES AND FLOWERS IN INDIA AND CEYLON.—The above is the title of a small book by Mr. D. McDonald, dealing with the vegetables and flowers of the white residents in India, and which seems to comprise nearly everything of value in the way of vegetables for the table, and plants to decorate the flower garden. Many of the latter are silent reminders of home, and would seem to be ill at home in tropical India, but as the area of the country is as immense as its climatic conditions are very varied, there are places doubtless to be found where the most unlikely plants will thrive with a due amount of care on the part of the gardener.—*Gardeners' Chronicle*.

INTERESTING DISCOVERY IN RELATION TO SUGAR CANES.—Much interest is evinced in scientific circles by a discovery which has just been made at Kew by Mr. D. Morris, the assistant director. Hitherto the sugar cane has been produced from cuttings or slips exclusively, as no one knew that there were such things as seed in the plant. After a long search Mr. Morris has at last discovered that each cane produces a number of seeds, from which it is possible to grow a variety of improved canes, and it is anticipated that by cross fertilisation and selection of the best seeds a considerable increase will be made in the yield of sugar in the tropical plantations. In instances the case of beet, which when first introduced for sugar-growing purposes yielded only about six per cent., but now, by the method of selection of proper seeds, it produces about 18 or 20 per cent. of saccharine juice. The seeds of the cane have been discovered in the panicle or flowery head of the cane, and the difficulty of finding them has been increased by the similarity of the glumes and the havis. It was only by the aid of a powerful microscope that tiny seeds were detected, and a number of plants were exhibited at the last meeting of the Linnean Society, with the seeds attached. At Kew Gardens there are some plants about nine inches high which have been grown from seed obtained from canes sent from the Barbadoes. The importance of this discovery cannot be over-estimated, as it will tend to drive beet sugar out to the market.—*Manchester Courier*.

DOES THE NUISANCE JUSTIFY FLOGGING?—The Grenada papers (Windward Islands) report the alarming extent to which the larceny of cacao and spices is being carried on. The landowners and merchants contend that nothing will tend to suppress "the habit" but a severe system of punishment. They have accordingly prepared a petition to the Government praying that whipping be resorted to as a deterrent, and that all business in cacao be carried on exclusively in the towns. It is said that in some parts of the island the pods are cut open on the trees and the beans stolen therefrom, leaving the pod hanging as if it were in "full" bloom. This petty thieving may be very tantalising, but one would think that something effective could be done for its suppression without resorting to flogging—a punishment to which a not unimportant section of opinion in the home country would be too sensitive to subject even burglars convicted of using firearms.—*Daily Chronicle*.

FARMING IN ENGLAND.—Mr. J. Allanson Piton, M. P., is of opinion that if the English tenant farmers were only placed in as good a position as their brethren in Ireland, a talk about "depression" would disappear. Here is a passage from a paper by him in the latest *Contemporary Review* :—

The depression of agriculture is no necessary result of free trade, but the inevitable consequence of a land system unadapted and unadaptable to the social and commercial life pursued by unshackled commerce. If land could be bought, sold, and transferred as easily as Consols; if rural England were less a rich man's playground and more a poor man's farm; if every occupant of land were absolutely free to make the best of it, had the same rights as in Ireland, and were wise enough to sacrifice game to crops; if delicately tilled soil and trim fences could be secured against the tramping and breakage of mounted Goths; if every future farmer had some years' scientific training and practice; if the needs of towns were studied, and obstinate buccic habit compelled to adapt itself to the market of the nineties instead of the markets of the 'teens; and if railway companies were forced to give rapid, sure, and cheap carriage for produce without partiality or favour—the land of this country would be well able to pay all and more than the charges laid upon it.

THE IMPERIAL TEA DUTY.—Says the *Madras Mail* :—

On the expiration in 1833 of the charter of the East India Company, which had held a complete monopoly of the tea trade, the *ad valorem* duty was abolished and differential duties of 1s 6d, 2s 2d, and 3s per lb. were substituted; but they appear to have worked badly and were abandoned in 1836 for one uniform rate of 2s 1d, to which in 1840 was added an additional five per cent. From 1840 the duty remained stationary till 1853, when it was reduced to 1s 10d; in 1854 it was reduced to 1s 6d; in 1855 it was raised again to 1s. 9d; next year it was reduced again to 1s. 5d, at which it remained till 1863, when it was reduced to 1s, and next year to 6d, at which it has remained ever since. The most curious circumstance connected with the tea trade is the displacement of China tea by Ceylon and India in the home markets. Five years ago India and Ceylon exported to the United Kingdom little more than half the quantity exported by China, yet in the short space of time intervening a wonderful change has taken place and we find that India and Ceylon exported in ten months of the year 1889 a total of more than 103 million lb., while China exported hardly 52 million lb. Such a transformation seems almost incredible, but is none the less true. The case of an article of produce in five years increasing in such a ratio on the one hand, and decreasing in a corresponding ratio on the other, has probably never occurred since

CATERPILLARS AND FRUIT TREES.

It is satisfactory to those who, like ourselves, have for many years past devoted attention to the subject of insect depredators, and to the means of dealing with them, to find at last that public attention is being aroused to the importance of the matter. At a meeting recently held at Evesham, the Mayor in the chair, the subject was discussed at some length. The ways and customs of the caterpillars were described in a letter from Miss Ormerod, as well as the various remedies proposed. Greased bands applied in October are very effectual, but injure the young trees. This injury is avoided by smearing the grease upon paper, or, as Mr. Wilson suggested at the Scientific Committee, on canvas, and not directly on the bark itself. Kerosene emulsions in the proportion of one pint of kerosene, half an ounce of soap, and four pints of water, to be used in the form of spray, were also recommended. But the most promising method is that which has been tried for many years in the United States and in Canada, and which, relying on the reports of such men as Professor Riley and Mr. Fletcher, we have earnestly pressed on the attention of our fruit growers for years past, but hitherto without avail. Either from our national slowness in adopting new processes, or from a fear of injury from the arsenical preparations, little or no progress has been made in this country with these valuable remedies; and yet the proportion used is so small that the risk to human life is too small to deter any person of ordinarily careful habits from making use of them.

Spraying with an arsenical solution should be done in the middle of April, when no fear need be entertained from the falling of the arsenic on to bush fruits grown under the Apples, though in the case of vegetables the case is somewhat different. The proportion of Paris green recommended is 4 oz. to 40 or 50 gallons of water (four ounces to forty or fifty gallons). In the 40 gallons there would be about 1 oz. of arsenic, and this would be distributed by the spray pump over, say, an acre of leaf surface. The danger, therefore, is clearly not in the proper use of the arsenic, but in the careless handling of the poison by ignorant or stupid people, a contingency which has always to be provided for.

We extract from the *Evesham Journal* the following letter, showing more explicitly how these arsenical preparations are used:—

"To every 50 gallons of water, mix well, and keep well stirred while using 4 oz. of Paris green. For Plums, as they are tender, and as the leaf is glossy, add three tablespoonfuls of fine flour from Wheat to make it stick on the leaves. Get a pan or dish, and make a paste of either or both, with a little water, as it mixes better with a bulk of water, and test it. If too weak, use 4 oz. to 40 gallons. If the Paris is a pure article, this will be found enough. Use 4 oz. to 40 gallons of water for Apple and Pear trees. Cherries may be treated the same way. Two dressings will, as a rule, be sufficient—1st, when the blossoms are falling and fruit beginning to form; 2nd, in twelve to fourteen days. Use your best judgment on this by observation. As soon as blossoms have fallen off, and while fruit is nearly upright, get a force-pump fixed, good, short, and handy, and in a barrel on wheelbarrow or wheels that can be moved handy to any place. Have a rubber hose of 1 inch by 8 feet long, or longer for tall trees; fix this on a handy pole, so that a man may shower ordinary trees without a ladder, and shower trees where insects are, much the same as a fine watering-pot rose would shower. Test your pump beforehand with clear water to get it to work satisfactorily. A large garden syringe may be used, but would take too long. A fine shower is what is wanted. You want two roses or nozzles, one for short and one for long distance. The ordinary pail of water is enough for a large-sized Apple tree. If heavy rain should follow as soon as the poisoned water is showered on trees, you will have to shower again. I have never known fruit to be hurt or any harm done by this, if used properly. The quantity is so small, and the time so long before fruit ripens, that every trace is

lost. In an orchard where there are cattle, sheep, &c., it would not be wise to let them graze for a few days after showering the trees with poison. If left for hay, this will not hurt the hay.

"As to the time for showering, I propose the morning, when the leaves are dry, or any time when dry, as the sun absorbs the water, and mineral poison settles. If the water is not sunned to near the same heat as the surrounding atmosphere, make a small fire and heat a few bricks before using, and temper the water in a tub, use a thermometer, and heat water to same degree as atmosphere. This is very important.

"Paris green is an arsenical poison. To shower when in bloom may do harm, and destroy bees. London purple, or arsenite of lime, is about equal to Paris green, and used the same way. Both are poisons, and should be used carefully. I recommend those that use one to use the other, and test them on separate rows of trees. Paris green or London purple costs here 1s. to 1s. 3d. per pound. This is the cheapest and most effectual way to destroy these pests by actual tests. As the young grubs eat a small part of leaf or fruit, a very small particle of this poison will kill, and save a great percentage of the fruit crop. I have used Paris green eight years, London purple two years, on fruit and vegetable."—ENOCH HAINES in *Evesham Journal*.—*Gardeners' Chronicle*.

LONDON PURPLE.

If we suggest that dealers should advertise their wares, we shall at once be considered to have interested motives—well, we have—the following narrative will show why. Our American friends make large use of various preparations of arsenic and other substances for spraying purposes, either for the attacks of insects or of fungi on various crops. We have repeatedly mentioned the fact, and urged our orchardists to adopt the methods employed with so much success in the States. Among other things, we have detailed the use of "London Purple." Some of our correspondents, attracted by our frequent reference to the subject, at length wrote to inquire what was "London Purple," and where it could be had? We knew or surmised it to be an arsenical preparation, and made sure that we should find reference to it in the authorised dictionaries of chemistry and pharmacy. But no! not one word could we find about the substance though it was evidently used on a very large scale. Finding books useless, we appealed to our chemical friends, to scientific chemists of high repute, to manufacturing chemists, to pharmacists, but all to no avail, till at length Mr. Holmes, of the Pharmaceutical Society, was good enough to put us on the right track. But in the meanwhile, finding that in London we could get no information as to "London Purple," we bethought ourselves that there was a London in Canada; and still later we bethought ourselves of our excellent correspondent Prof. Riley, the Director of the United States Entomological Department, and he, with his customary kindness, gave us the information we wanted, adding that Hemingway & Co., of London, aniline dye manufacturers, have given the name in contradistinction to Paris Green, and have established a branch house in New York, the sale of this valuable insecticide being, it is believed, one of their most important transactions. Two reflections occur to us on this story, one is that manufacturers should advertise (in the *Gardeners' Chronicle*, of course—anywhere else they like), the other is, that this is one more illustration of the abominable time-wasting, trouble-giving, truth-concealing nature of "popular names!"

This powder is obtained in the following manner in the manufacture of aniline dyes: Crude coal-oil is distilled to produce benzole. This is mixed with nitric acid, and forms nitro-benzole. Iron filings are then used to produce nascent hydrogen with the excess of nitric acid in the benzole. When distilled, aniline results; to this are added arsenic acid, to give an atom of oxygen which produces rose aniline, and quicklime to absorb the arsenic. The residuum, which is obtained by filtration or settling, is what has been denominated "London purple," the sediment being

dried, powdered, and finely bolted. The powder is, therefore, composed of lime and arsenious acid, with about 25 per cent. of carbonaceous matter which surrounds every atom. Experiments which we made with it in 1878, says Professor Riley, impressed us favourably with this powder as an insecticide, and its use on the Colorado Potato-beetle by Professors Budd and Bessey, of the Iowa Agricultural College, proved highly satisfactory. We were, therefore, quite anxious to test its effect on the Cotton-worm in the field on a large scale, and in the winter of 1878-79 induced the manufacturers to send a large quantity for this purpose to the Department of Agriculture. The analysis made of it by Professor Collier, the chemist of the Department, showed it to contain:

	Per cent.
Rose aniline	12.46
Arsenic acid	43.65
Lime	21.82
Insoluble residue	14.57
Iron oxide	1.16
Water	2.27
Loss	4.07
	100.00

Through the liberality of the manufacturers, Messrs. Hemingway & Co., a number of barrels of this powder were placed at our disposal during the season of 1879, and distributed to various observers and agents in Georgia, Alabama, and Texas. Early in the spring of the following year, Mr. A. R. Whitney, of Franklin Grove, Ill., found it to be a perfect antidote to the canker-worms, which had not been prevented from ascending his Apple trees.—*Gardeners' Chronicle*.

PLANTS GROWN FOR SALADS.

M. Henri de Vilmorin, of Paris, who, metaphorically speaking, has been described as "a horticultural-agricultural giant," delivered an interesting address on the afternoon of the 25th March before a large and fashionable audience on "Plants Grown for Salads."

M. de Vilmorin, who spoke fluently in English began by saying that the taste for green, fresh, crisp, uncooked vegetables was natural and common to most men. Such an appetite was a healthy one and in accordance with the recognised laws of nutrition. Vegetables so served, that is, uncooked, at tables were usually known as salads, and they supplied the elements necessary for the preservation of health, just as the flesh-forming and heat-giving properties were furnished in the richer articles of diet. Salads contained a relatively far higher proportion of mineral matter chiefly salts of potash, than ordinary food, for though all vegetable contained that substance in considerable quantities, it was lost to nutrition by the cooking process. Although salads were ordinarily understood as being solely made with green or partially-bleached leaves, every part of the plants might be and were used in some places. In fact, salads comprised things so various as roots, celeriac, radishes, rampion, &c.; bulbs or underground stems, onions, stachys leaves, such as lettuce endive, cresses, corn salad, and many more; leaf stalks, as celery; stems as asparagus; bracts, as in artichoke; flowers, as in nasturtium; fruits and seed pods, as cucumbers, capsicum, tomatoes, and so on. M. de Vilmorin observed he would treat the subject generally from two points; first, the vegetables used in France as salads and brought into Paris markets, and secondly, the operations required for the proper cultivation of salads. Bleaching was one of the most important of these operations, for by that means, intelligently applied, vegetable almost uneatable for salads were rendered palatable and pleasant. The Continental and British ideas of what constituted a salad differed very materially. Salads proper on the Continent were such vegetables as formed a distinct dish, dressed with oil, vinegar, and, of course, salt and pepper. These were often served with meat. Then there was another end, less number of salads made up in many ways of roots,

bulbs, &c. M. de Vilmorin then described the season for each peculiar class of vegetable and form of salad, "Common and proper." Speaking again of "salads proper," he observed that lettuces and cabbages were to be had, with a little care, all the year round. An inverted pot or a glass cover in the winter months formed a suitable protection for these vegetables, the types and modes of preparing which he next described. Common chicory was little used, except when bleached. Next to cabbage and lettuce, the French salad-eaters consumed most of the plants known as curled and Batavia endives. Green cultivated dandelion could be had also all the year with little trouble, as also could watercress. Referring to other plants used as salads in France, the audience were told that salsify tops made a fine tender salad, and had nice nutty flavour. Then there were celery, chervil, chives shallot, borage flowers, mustard and rape seedings, &c. Referring to salads eaten as an accompaniment to meat, M. de Vilmorin enumerated over a score of plants among them the well known French dishes of French and kidney bedens and lentils. The flowering in most plants was developed under the action of light. By excluding light, or practising what was technically termed "bleaching," the vegetable matter was not only made whiter, but the plants themselves were made more tender and materially improved to the taste. In connection with "bleaching," he wished to bring forward and press upon the attention of the English the claims of the dandelion and common, or bitter, chicory. The dandelion had been cultivated and grown as a vegetable for over fifty years near Paris. It was sown in the fields in April, in ridges about two feet apart. The growing plants were tended and weeded and watched like any other vegetable, and the soil was heaped up over the sprouting leaves to secure their being "bleached." So cultivated, it sold in the market at prices of from 8s to 20s a cwt. The dandelion was also set out in the same way as common chicory. In gardens the plants were set much closer, and the leaves were sometimes bleached by over-turned pots. There were several varieties of dandelion cultivated in field and garden, and all of them, when suitably made up, were most agreeable as salads. The same applied to chicory and a host of other plants equally available for use as winter salads.—*Pioneer*.

PLANTING:—TOBACCO IN DELI.

The *Deli Courant* of the 2nd April reports favourably on tobacco crop prospects there during one month before, the weather then proving as hot and dry as could be wished. Hardly any rain fell, so that felling and burning operations could be actively proceeded with, much jungle having been cleared away from the fields. Up-country, on many estates, planting has already taken a start, but it wholly depends on the raininess or otherwise of the weather whether much will come of this early cultivation. Generally field work was actively gone on with in March. The forwarding of last year's crop continues in full swing, with every prospect of the whole outturn being delivered in Europe before summer. The stocks in the hands of wholesale dealers there will probably bulk, the largest about July next.

Telegrams bring word that all Deli tobacco companies' shares at Amsterdam have risen considerably in quotation, in consequence of the favourable crop outlook.

The Deli Planters' Association has authorised its committee of management to subsidise direct steamers plying from there to China, the resulting outlay being borne proportionately by the members.

Recently, on the departure of the "Sachsen" from Singapore, difficulties arose as to rapid loading with tobacco in bales during a rain shower, the Master apparently not setting store by slow but sure shipment. Tobacco seems to be a risky article, owing to its so readily becoming damaged, and even when rain does not take effect on the leaf, it wets the matting of the bales and gives rise to fermentation.—*Straits Times*.

THE ABUSE OF COFFEE.

Dr. F. Mendel (the *British Medical Journal* says) has recently enjoyed opportunities of studying the results of an unbridled abuse of coffee, and his results are now published. The great industrial centre round Essen includes a very large female population. While the women of the working classes in this country are often addicted to dosing themselves with tea that has stood too long, it appears that the workmen's wives at Essen drink coffee from morning till night. Some consume over a pound of Ceylon coffee weekly, and one pound contains over sixty-four grains of caffeine. In consequence, nervous, muscular, and circulatory disturbances are frequent. The nerve symptoms are characterized by a feeling of general weakness, depression of spirit, and aversion for labour, in even industrious subjects, with headache and insomnia. A strong dose of coffee causes the temporary disappearance of all these symptoms. The muscular symptoms consist of distinct muscular weakness, and trembling of the hands even during rest. The circulatory symptoms are marked by a small, rapid, irregular pulse, and feeble impulse of the apex of the heart. Palpitations and heaviness in the precordial region are frequent. The hands and feet feel very cold, and the complexion becomes sallow. Dyspeptic symptoms, chiefly of the nervous type, are very common. These coffee-drinkers cannot be cured by simple abstinence from their favourite drink, with substitution of milk as a beverage. They require rest from work, open-air exercise, cold ablutions followed by friction, and small doses of brandy.

THE BUDGET AND THE TEA DUTY.

The state of the home tea market is calculated to raise the suspicion that some uncertainty still prevails as to the effect of Mr. Goschen's budget. In the first place we are asked whether the reduced duty of 4d per lb. has already come into force, and if not when it is to begin to operate. Our belief is that as the budget year closes on March 31st, any alteration in duties takes effect from 1st April, but that such alteration cannot be finally recognized until a Resolution embodying the tea-duty portion of the budget passes Parliament. We suppose therefore that rebates will be granted on all tea paid for at the old duty when instructions come to the Customs, to say that the new rate has been sanctioned. The following extract from the "Budget" article in the *Encyclopædia Britannica* is worth quoting:—

Budget (lit. a bag or small sack), the name applied to an account of the ways and means by which a minister of finance proposes to defray the expenditure of the state. In the United Kingdom the chancellor of the exchequer, usually in April, lays before the House of Commons a statement of the actual results of revenue and expenditure in the past finance year ending March 31st showing how far his estimates have been realized, and what surplus or deficit there has been in the income as compared with the expenditure. This is accompanied by another statement in which the chancellor gives an estimate of what the produce of the revenue may be in the year just entered upon, supposing the taxes and duties to remain as they were in the past year, and also an estimate of what the expenditure will be in the current year. If the estimated revenue, after allowing for normal increase of the principal sources of income, be less than the estimated expenditure, this is deemed a case for the imposition of some new, or the increase of some existing, tax or taxes. On the other hand, if the estimated revenue shows a large surplus over the estimated expenditure, there is room for remitting or reducing some tax or taxes, and the extent of this relief is generally limited to the amount of surplus realized in the previous year. The chancellor of the exchequer has to take parliament into consideration on his estimates, both as regards revenue and expenditure; and when the taxation and expenditure obtain the assent of

parliament, the results as thus adjusted become the final budget estimate for the year.

The above note was written for yesterday's daily issue. This morning brings the mail and Mr. Goschen's budget in full with the criticisms of the press and much general information. So far as we can see, the reduction of 2d in the duty took the tea trade rather by surprise and opinions were divided as to the benefit to British-grown teas. However, although low-class and China teas were expected to score at first, it was felt that the good character of Ceylon and Indian teas was too well established to be affected and that all classes would desire to drink better teas.—As regards the date of the new duty coming into effect, we learn it was fixed a month later than the new budget year or for 1st May, thus explaining the course of the market recently which had puzzled a good many. We have further from a late *Globe* (18th April) the following important explanation:—

Giving Effect to the Budget.—In anticipation of the Chancellor of the Exchequer's financial statement, instructions were, says the Press Association, last evening sent out to the Excise authorities in all parts of the country respecting the increase of 6d per gallon on spirits. The duty will be charged on a higher scale forthwith, the necessary preliminary formality having been complied with as soon as the House of Commons assented to the first Budget resolution. In the lobby last evening the prevailing impression was that the Government would adopt a similar course in regard to tea duty, and would instruct the Customs officials to be prepared to make the reduction as soon as the resolution dealing with the subject received the sanction of the House. We are informed, however, that the usual practice will be departed from to some extent in this case. The Government, instead of allowing a drawback for the purpose of recouping the traders for the amount of duty paid on existing stocks, propose to give the traders a fortnight in which to adjust matters and the duty will accordingly be paid on the higher scale until May 1st. This, it is held will meet the equities of the case, because, in view of possible reduction in the duty, the tea taken out of bond during the last two months has been abnormally small.

MR. GOSCHEN AND THE TEA DUTY.

This is what the *Home and Colonial Mail* says under its Notes on Produce and Finance on April 18th:—

Although there have been plenty of rumours on the subject, it was not generally expected that the Chancellor of the Exchequer would, in his Budget proposals, touch the tea duty. The reduction of the duty from 6d to 4d has been received with some surprise in Mincing Lane. The reduction will, no doubt, give a spurt to the trade.

It is clear from Mr. Goschen's remarks and his admission that he is not in favour of the abolition of the duty, that the present reduction is all that is to be looked for from him. He said:—"The tipplers shall relieve tea. The loss upon the tea duty will amount to £1,500,000. I know it has been said the reduction of 2d will not benefit the consumer. But I am not prepared to admit that argument. We have to look to our responsibility, and our responsibility is that this duty represents a very large proportion of prime cost of the article. Now, if tea were sold, as it should be sold, to the consuming classes at something like cost price, it would appear at once what an enormous relief would be given by 2d in the pound. But the relief is concealed by the fact that the middleman walks away with a large proportion of the price paid by the working classes for their tea. Will it be believed that in many villages the working classes pay as much as 2s, 2s 6d, and 3s for tea which practically, with all costs included, does not cost more than 11d or 1s, and which many persons in reduced circumstances buy of good quality at 1s 6d. If you take the price of 1s 6d and then say that upon that price you are going to reduce

by 2d., it is an appreciable boon you confer on the consumer. It would be a very great satisfaction if advantage can be taken of this reduction by those who are so interested to insist upon receiving their full share of this relief which will be given from the public purse, and that they should through better organisation see whether it is not possible to buy this article of primary necessity, and so important to the whole of the working classes, upon better terms. I will frankly say before parting from this subject that I am opposed to the total abolition of the tea duty. There is no doubt that tea is the one article through which those who neither smoke nor drink contribute to the revenue; and therefore I consider it right that the tea duty should be maintained, and I should be sorry if we cut off altogether any of the sources of our revenue. As regards abolition, I can well imagine that differences of opinion exist but I think that under the circumstances of the case, looking to the way in which the surplus has been created, and to others to which I shall ask the attention of the Committee later on, I think that justice has demanded the application of this portion of the surplus in the manner which I have indicated."

THE CEYLON TOBACCO COMPANY. (LIMITED.)

ANNUAL GENERAL MEETING.

The annual general meeting of the shareholders in the Ceylon Tobacco Company, Limited was held within the registered office of the Company, No. 42, King Street, Kandy, on Saturday, the 3rd May, at 2 p.m. when the following shareholders were present:—Messrs. W. Pole Fletcher, H. K. Rutherford (represented by Mr. L. P. Fisher), Wm. Mills, G. A. Talbot, Hugh Fraser, T. O. Huxley, C. S. Armstrong, T. C. Owen, J. Hill, A. Schappe (representing German interest), Hon. Mr. Thos. North Christie, Mr. A. Philip; by proxy, Messrs. A. G. K. Borron, Norman W. Grieve, Joseph Fraser, D. R. Marshall, H. D. Deane, J. M. Murdoch, James Tennent Emerson, William Hunter Reid, Alexander Tait, W. L. Murray-Menzies, Wm. Milne, S. M. Burrows, Mesdames Florence E. Ragot, Susan Frances Talbot, Mary C. M. Hill, and Edith Dick.

The notice calling the meeting having been read, the Directors' Report was read by the Secretary of the Company, Mr. Philip.

Its adoption was moved by the Hon. Thos. North Christie, Chairman of the Board of Directors, was seconded by Mr. Wm. Mills, and carried unanimously. Mr. G. A. Talbot moved that the following gentlemen be appointed Directors:—Hon. T. N. Christie, Messrs. Jas. Hill, T. C. Owen and C. S. Armstrong, Mr. T. C. Huxley seconded the motion and it was unanimously carried.

REPORT OF THE DIRECTORS OF THE CEYLON TOBACCO COMPANY, LIMITED.

To be presented to the Shareholders at the Annual General Meeting of the Company, to be held within the Registered Office of the Company, No. 42, King Street, Kandy, on Saturday the 3rd day of May 1890, at 2 o'clock in the afternoon.

The Company was incorporated under the Joint Stock Company's Ordinance No. 4 of 1861, on the 28th of April, 1889, before which date it was not possible for the Directors to act on behalf of the Company. Hopes had been entertained that it might have been possible to have commenced operations early in 1889, but the unavoidable late date of the Company's incorporation and other circumstances decided the Board that it was not desirable to attempt to put any land under tobacco until the current year. Early in September of last year your Directors, in conjunction with the Ceylon Tea Plantations Company, availed themselves of the presence in Ceylon of an experienced Sumatra and Borneo planter Mr. H. Innis, and obtained from him a general report on the prospects of tobacco-growing here, and also by kind permission of those interested, remarks on some of

the clearings in the vicinity of Kandy and on the tobacco there produced. The following is a quotation from Mr. Innis's Report:—"Having visited the tobacco clearings and sheds at * * * * * and * * * * *, I am quite of opinion that tobacco can be successfully grown in Ceylon. The clearing I saw on the * * * * * estate was equal to any, and better than most, I have seen in Sumatra, the soil being superior to most. The soil at the * * * * * estate is well suited to the cultivation, and the general lay of land good. There is no reason why that and similar land should not with proper manipulation produce wrapper tobacco equal to the staple of Sumatra. The tobacco now in the sheds, though chiefly grown from Havanah seed, was of better quality than I expected to see, and is as good if not better as that from most districts in Sumatra. The general principles of the cultivation and preparation are evidently understood, but in some minor matters (which however are very important if a really good leaf is to be procured) some alterations and improvements are necessary. Exclusive of lands taken over under an agreement with Mr. Fritz Meyer, 534 acres of land have been purchased at a cost of Rupees seventeen thousand two hundred and eighty three (R17,283) and a considerable further acreage has been arranged for. Towards the end of 1889 the Directors were approached by Mr. Schappe, the attorney of Mr. Meyer, with a view towards an amalgamation of interests; and eventually an agreement was entered into under which this Company took over all Mr. Meyer's lands &c., on terms that the Directors consider to be such as will greatly benefit the Company. In terms of this agreement, 1,423 acres of land, buildings, implements, &c. to the value of about R48,000, will be taken over, payment being made entirely in paid up-shares of the Company. The services of Mr. J. K. Ingleton as Manager were also agreed for, and that experienced tobacco planter has for the past three months been in charge of the Company's operations on the Arampolla property in the Kurunegala District, where a most successful crop was grown last year, the quality of which Mr. Schappé considers very good. It is hoped that about 200 acres will be planted during the next 2 months, while on the Matala Estate 100 acres are now being prepared. The Directors estimate that, with a suitable season, 120,000 lb of tobacco should be secured, costing, landed in Colombo, about 30 cents per lb. If this anticipation is realized, it will add tobacco to the list of products which Ceylon is able to produce more cheaply than almost any other country. The utilization of the land after the tobacco crop has been taken off it, has had the careful consideration of the Directors, who have decided that the establishment of suitable permanent products on the Company's estates will tend greatly to economy in working, regular profit, and the stability of the Company. In pursuance of this decision, one hundred and fifty (150) acres of coconuts in Kurunegala and one hundred (100) acres of tea in Matala will be planted before the close of this year. The Directors have appointed Mr. Guthrie, Auditor for past year.

DARJEELING.—Most people are beginning to wonder if it ever will rain here again. Throughout the district it is the same question from Silligorie to Kalimpong. The fact is last year's rains were very short, as regards inches fallen, and to add to that the rains closed unusually early. The result, of course, is that tea is suffering a good deal, and red spider blight is very bad on a large number of gardens—I might say all—both in the Terai and hills. From what I hear of the new tea gardens over Dumsong way, the owners have evidently made a very happy hit in taking up the land, as it is admirably adapted for tea, and consequently, the bushes grow both rapidly and vigorously. The chief drawback at present is want of roads; but this, of course, is always the case in newly opened-up country, and rights itself in the long run.—*Indian Planters' Gazette*, March 25th.

PLANTING IN NORTH BORNEO.
BRITISH BORNEO TRADING AND PLANTING
COMPANY.

The third ordinary general meeting of the British Borneo Trading and Planting Company (Limited) was held at the Cannon-street Hotel on the 30th ult.; Mr. J. J. Dunn (chairman and managing director) presiding.

There were three things which we proposed to ourselves, and hoped to accomplish. These were, first of all to increase the capital to bring us within the regulations of the Stock Exchange; secondly, to get a quotation for our shares; and, thirdly, to pay a dividend. I am happy to say that we have accomplished these three things, and our company is now in a very much better position than it was when we presented our last balance-sheet. The capital account now stands at £83,410, leaving a balance of nearly 17,000 shares still to be issued; and although we have ample capital at the present time, I have not the least doubt that we shall find useful employment for the unissued capital in developing our estates later on. As stated in the report, we have issued the shares since last April at 5s. premium, and we hope to issue the balance at the same price, if not more. With regard to the property account, you will notice that the estates stand at the same value as in the last balance-sheet—namely, £29,000. At the last ordinary meeting I stated that if our estates, which then amounted to 100,000 acres, were valued at the same price that other companies had paid for theirs, it would figure out at from £150,000 to £250,000. I think that estimate has been very fairly fulfilled, as in the meantime we have disposed of about 30,000 acres at an average of nearly £3 per acre. Therefore I think we were fully justified in keeping the value of the balance of our estates of nearly 70,000 acres at £29,000, and not writing off anything further. In fact, if the 70,000 acres were valued at only half of what we have sold a portion at, it would still represent £105,000, which is a very substantial asset. I may also mention that the £29,000 includes the value of the fibre-machine rights for Borneo. As stated in the report, we have formed two subsidiary companies, each with the nominal capital of £100,000, and as we hold over £63,000 in the shares of these companies, you will be glad to hear what their position and prospects are. In forming these companies we agreed to act as agents and general managers. That position is very advantageous for them, and also for us, as I am quite sure the planting companies who only depend upon their estate manager are at a disadvantage as compared with those who have outside firms or companies to act as their local agents. If they want coolies, stores or anything of the kind the estate manager is not able to leave the estate, and if he does so it is very detrimental to its success. With regard to the Suanlamba (Borneo) Tobacco Company (Limited), the capital was fully subscribed. The estate formed a portion of those formerly owned by the Chinese Sabah Company of Shanghai, and we have purchased this estate from the Government of British North Borneo, they having a mortgage over it. It had previously produced first-rate tobacco, which was exhibited at the Colonial Exhibition, but last year it was not under cultivation, so that this year we had to obtain a fresh supply of coolies and assistants for the estate. It was intended that Mr. Johnstone, our planting manager, should superintend this estate, but he has given it as his opinion that it is absolutely necessary the manager should reside on the estate, and that a visiting superintendent only will not do. He, therefore, engaged the services of an experienced man (Mr. Fockens) from Sumatra, and this gentleman went to reside on the estate early in the year. He had excellent testimonials, and Mr. Johnstone has confirmed these by stating that, in his opinion, Mr. Fockens is quite as capable as himself, and does not need any superintendence. I am sorry to say there has been great difficulty in obtaining labour on this estate, owing to the number of new companies which were formed at the beginning of the year for planting tobacco. The brokers in China formed a ring, and ran up the prices, so that before you could obtain a single coolie you had to pay \$100, or over £15,

for each man, and then you have to run the risk of his running away, or his dying when he arrives at the estate. It is an almost prohibitory price, but the Chinamen saw their opportunity, and used it. This has interfered seriously with the development to the estate as we intended—in fact, not only our estate, but every state in Borneo has suffered in a similar way, from it being impossible to get the number of coolies required. Mr. Fockens and his assistants have suffered from fever a great deal this year, but both Mr. Fockens and Mr. Johnstone are of opinion that as soon as a larger area of country is opened up this will disappear. With regard to the Sagaliud estate, it was under cultivation last year, and therefore had the advantage of having seasoned coolies. Such men are more easily dealt with than strange men, especially Chinamen, and, that being so, this estate has got on more favourably than the Suanlamba. From the reports of our general manager, and from official sources, we learn that the Sagaliud estate is the most flourishing and forward in all Borneo of any tobacco estates. Mr. Johnstone, writing home recently, states that he estimates from it alone 600 piculs of tobacco as the crop from it. That is a very fair crop, and bears out our estimates as to what the prospects of the company would be. Our general manager—Mr. Hughes—writes home that he is proposing to open two new estates next year, and he has already commenced felling timber for clearing the estates. It will be a question with us whether we shall develop these estates with our own capital, or form them also into subsidiary companies. The chairman went on to say that the company had obtained the services of a medical adviser—Dr. Parsons—who had gone out with his wife and family. He was now residing at Sandakan, and would act also for the tobacco companies. As to tobacco planting generally, the crops on this company's estates, as well as those of other companies, went to show that there was not the least doubt that Borneo would compete successfully with Sumatra as regards the quality of the tobacco. It was a question of management and labour, and he believed they would soon be able to overcome every difficulty in that respect. They had sent some of their assistants to India to obtain labour from that quarter which would cost about a fourth of the cost of Chinese labour. The Dutch Government in Sumatra had endeavoured to obtain this Indian labour, but it had been refused by the Indian Government, and as there could be no objection to Indian coolies going to a British colony, there was every hope that, with Indian labour they would be able to work much more cheaply and advantageously than in Sumatra. As to the sawmill department, the accounts not having been sent, have prevented his giving the shareholders as much information as they would have liked. This was chiefly to the breakdown in health of the accountant sent out in the beginning of the year who had to return home. This caused some confusion and delay before he could be replaced. At the same time, he was able to give some idea of the business from the letters and reports they had received. Mr. Boulby, whom he left in charge of the mill in December last year, was going to ship 1,000 logs to China, and had received another order for 2,000 logs for the same quarter. Letters subsequently received informed them that the vessel chartered to take those 1,000 logs to China was only able to load a little more than half that quantity, owing to a miscalculation. On the arrival of the cargo in China the merchants to whom it was consigned stated that in their opinion the timber was not sufficiently seasoned, that being also the general opinion. The board thereupon wrote to Mr. Boulby to stop shipping hard wood until it was properly seasoned. Some timber had been sold here, and it was put down in the balance-sheet at an average of £5 a ton. A small portion had realised at the rate of £17 10s. a ton, and from what they had seen of the timber here there was not the least doubt that if it was seasoned and sent home in proper condition, there would be an unlimited demand for it, and it would show a very good profit.

The mill had been largely engaged during the past six months in executing an order for a local company, for cutting timber supplied by Messrs. Abraham and Co.

This is a contract made by Mr. Boulty, and although they did not like cutting other people's timber, still, they had to carry out the contract, which had seriously blocked that part of the business. The reports from the manager stated that the local sales, which were chiefly for soft woods, more than covered the current expenses of the mill. The last letter stated that, besides a very large stock of sawn timber seasoning in the yards and sheds, there were upwards of 13,000 sound logs also seasoning at the mill, so that no doubt the accounts would show a large stock of timber in hand. The work of extending the mill was going on rapidly. They were putting in a large frame saw bench, and they were also erecting an engineer's repairing shop and foundry, as any part of the machinery which now went wrong had to be sent to Singapore or Hong Kong, which meant serious delay. There had also been some difficulty with the belting, on account of the dampness of the climate; but they were now getting new belting made of camels' hair, which, he believed, would obviate the difficulty. During the year the board had appointed Mr. Hughes as general manager, and from all sides they heard of his working in the most energetic and earnest manner on behalf of the company. During the months of April and May Mr. Hughes went to China to interview the merchants there, and see what market there was for the timber. The result of his visit was to stop shipping timber there at present; but the board had received a telegram the other day that he was loading a sailing vessel of 1,600 tons with Billian for China. The board had found it advisable to dispense with the services of Mr. Boulty, and in his place they were endeavouring to get a very able man, whose name he was not permitted yet to mention. This gentleman was now at the head of a large concern in the East, and should the company obtain his services, there was not the least doubt that the mill would soon be in a most flourishing state. The difficulties with regard to freight still continued. At the last meeting he stated that they proposed to take shares in a shipping company in Singapore, and they had offered to do so if the contracts were exhibited for the purchase of the vessels. That, however, was declined, and the arrangement fell through. He was strongly of opinion that in future it would be absolutely necessary for the company to possess a small steamer, say of 50 tons, for the purpose of taking timber round to Singapore, Hong Kong, or even to Australia. This matter would certainly engage the attention of the board, and as he (the chairman) was leaving for Borneo next week, he would be in a better position to discuss such matters, not only with the general manager, but also with the merchants, as he would prefer to own any vessels on joint account with the local merchants in Singapore or Hong Kong. This would give them a far better chance of success than they would have if they tried to work them by themselves. The Chairman concluded by proposing the adoption of the report and accounts.

A dividend of 4 per cent. was then agreed to making a total distribution of 10 per cent. for the year, payable on and after Oct. 1.—*L. & C. Express.*

DRIED FLOWERS AND THE INFLUENZA.—From our contemporary, the *Chemist and Druggist*, we gather the following items:—First, that one of the effects of the recent epidemic has been a considerable consumption of dried flowers popularly used for infusions, such as Borage, Corn Poppy, Marsh Mallow, Coltsfoot, and Linden tree flowers. The supply in stock, it is said, has run very low, and none can be expected before the coming season. Second, that with reference to the supply of camphor, the demand for which has much increased of late, that the mail reports from Hongkong state, that 250 piculs of Formosa camphor had arrived there, and had been shipped to Europe. It is further asserted that the quantity of camphor used in the manufacture of smokeless powder is exceedingly large, and that it enters into the composition of that article to the extent of 10 per cent. of the weight. In consequence of this there are now no old stocks, the manufacturers being compelled to refine the fresh arrivals, thereby losing about 5 per cent. on the weight.—*Gardeners' Chronicle.*

BEEES IN GERMANY.—We read in the *Alsace and Lorraine Bee Journal* that, according to an estimate presented to the German Reichstag, the culture of bees brings in yearly a total net profit of 17,000,000 marks to those engaged in the occupation. This is a much larger sum than anyone had imagined, and which may be still further augmented.—*Gardeners' Chronicle.*

DR. GILBERT, who, in connection with Sir John Lawes, has devoted a life-time to the elucidation of the principles on which agriculture is based, is to be honoured, or rather the University of Edinburgh is going to confer honour on itself, by the conference of the degree of Doctor of Laws on the celebrated agricultural chemist of Rothamsted. The right Hon. H. Chaplin, who has only just put the harness on as Minister of Agriculture, is to receive the same degree.—*Gardeners' Chronicle.*

"KEW BULLETIN."—The March number contain articles on "Indian Yellow," a dyeing material prepared from the urine of cows fed upon Mango leaves; also on Bombay Aloe fibre procured from *Agave vivipara*, the cultivation of which in waste land near Bombay, for the sake of its fibre, is strongly recommended. Barilla manufacture in Egypt is the subject of another article, the barilla being carbonate of soda, contained in the ashes of certain seaside and salt lake plants like our *Salicornia*.—*Gardeners' Chronicle.*

RESOURCES OF INDIA.—Mr. Bryce, M. P. in giving an address before the Aberdeen Chamber of Commerce spoke as follows:—

Cotton, of course, had been also very largely produced and had received a great stimulus from the American Civil War. Coffee was grown in the south, particularly on the Neilgherry Hills. Quinine was cultivated very largely in Ceylon and on the Neilgherry Hills, with the best possible results; and in this regard he referred to the value of quinine as the very best specific against malaria, one of the greatest plagues and curses of India. It was probably on the whole diminished, and it might be that we should discover some better means of dealing with it than medical science had yet discovered, but he had been often told by Europeans in India that one of the greatest tribulations which they had in their lives was the constant guard that they were obliged to keep against the assaults of this disease, producing agues and intermittent fevers, not so dangerous in itself as dangerous, because it weakened the constitution and laid persons open to attacks of other more dangerous acute diseases. Jute and indigo were also very largely produced, tobacco was cultivated to some extent but the largest development in recent years had been in connection with tea. Nothing was more remarkable than the extent to which during the last 40 years in the planting of tea had advanced everywhere in India. It was now one of the largest trades in the country, and he believed he was not wrong in saying that the quantity of tea consumed in Europe now coming from India was very nearly equal, and probably fully equal, to what was coming from China. The tea-planting, it might interest them to know, was very largely carried on by Scotchmen. He was greatly struck in the upper plantations of the Himalaya, at Darjeeling and the North-West Provinces, and particularly round Darjeeling and Assam, to find how very large a number of tea planters came from Scotland. It was quite curious to notice how constantly one heard the Scotch accent, and discovered the person from whom it came was a tea planter driving a thriving trade on the slopes of these hills—(applause). He might say in passing, that he was greatly struck by the number of Aberdonians he met in different parts of India—(applause)—many of them merchants, many of them in the army, and a very large number occupying important posts in the Civil service. He supposed it was partly owing to the excellence of the education given in the University of Aberdeen—(applause)—that so many Aberdonians had entered the Indian Civil Service by competition and that once being in, they had shown the characteristic aptitude of their country and their county by rising with very rapid strides—(applause).—It was quite interesting to him to find how many men had attained eminence in India who hailed not only from Scotland, but from the North-East of Scotland.—(Applause).

ALL ABOUT THE TOON TREE.

(From the Hills.)

THE NICKER TREE—THE 'WHITE TOON' THE REAL SIMON PURE, AND THE 'RED TOON' ONLY A VARIETY.

I am indebted to the accomplished Director of the Royal Botanical Gardens for the following information regarding a tree which, as much as the *kina*, perhaps, adds to the floral glories of our forests at this season of the year, the *kina* showing a crown of white blossom and the "wild toon," as we call it, from its striking resemblance to *Cedrela toona*, being adorned with primrose-coloured flowers. Dr. Trimen writes:—

"The leaves you sent are those of *Meliosma Arnotiana*, a very beautiful and conspicuous tree of the hill forests in April when covered with sheets of cream-coloured blossom. I fear its beauty is its principal recommendation, the wood being poor and soft. It is occasionally used for house-work however in the hills, and the lowcountry carpenters have given it a name *nika-davulu*. Like most of our hill trees it has no real native name, so far as I know."

I suspected that the timber could not be superior, in consequence of our carpenters passing over these trees. Moon notices the tree as *Guilandina*, *Bonduc*, or *Nicker* tree and states that *Davula* signifies a drum and *nika* a knee. In the "Treasury of Botany" I find under *Guilandina*:—"G. *Bonduc* has solitary prickles on the leaves, and the seeds are yellow. G. *Bonducella* differs by its prickles being in pairs, and its seeds lead-coloured. Seeds of both are very hard, and beautifully polished, and are called *Nicker* nuts or *Bonduc* nuts, the latter being derived from the Arabic, *Bondog*, signifying a necklace, the seeds being commonly strung into necklaces, bracelets, rosaries, &c. The kernels have a very bitter taste, and are employed by Indian doctors as a tonic and febrifuge. The roots also are said to possess similar properties: indeed, the Sinhalese employ every part of these plants medicinally. The oil obtained from the seeds is supposed to be useful in convulsions and palsy."

In consequence of my sending Dr. Trimen a leaf of what we know as "white toon" and of which to our intense disappointment we have a large number of plants grown from seed sent to us as that of red toon,—the true *Cedrela toona*,—Dr. Trimen added:—

"I do not think I know the difference between what the planters call here 'red' and 'white toon.' I only know one *Cedrela toona* (which has red wood and is I should suppose 'red' toon), the toon tree generally. I have hitherto supposed that the 'white' toon of Ceylon (who invented this name?) was the W. Indian *cedrela*, *C. odorata*, the 'sweet cedar' of Jamaica, which has been a good deal distributed from the gardens of late years in the form of young plants, from seed obtained in 1885. But the plant you now send leaves of is just ordinary *C. toona*, and I should be glad to know why it is 'white' toona, and what is the distinctive mark from the 'red' sort."

In reply I sent Dr. Trimen young plants, branches and pieces of bark of each variety of toon, which I am confident will convince him that the "white toon" is a very distinct and, at least for high altitudes, a very inferior variety. It has no odour, except that it stinks in the nostrils of planters who have tried it, and it can have no affinity to the fragrant Jamaica plant. The stem and foliage are green and succulent looking, only some of the young leaves having a faint touch of pink at the points, while the true red toon is intensely red in branches and foliage from the nursery onwards. The latter grows rapidly up to an altitude of 6,500 feet, while the white toon makes very slow progress at 5,000 feet altitude. Where it has been grown in this district until a few years old, the tops have been eaten by swarms of caterpillars, a pest from

which the red toon is exempt. The leaves of the red toon are serrated, but not one leaf in a hundred of the white toon is so marked. The branchlets of red toon almost invariably end with two opposite leaves; those of the white with one at the point. On the purely botanical question of substantial identity or distinct variety, Dr. Trimen's scientific opinion will, of course, be decisive. But we as cultivators know that what we call "the white toon" is, in elevated regions, a slow grower, is liable at a few years old to be frightfully infested with insects, while, if the trees attain maturity, we have good reason to suspect that the timber will be white and inferior.* The red toon, on the other hand, vies with the eucalypti in rapid growth. I have trees near the Lake Bund at Nuwara Eliya, which will be planted out only four years in September and all ready some of them approach forty feet in height, most of them fine straight stems without a branch. A recent visitor from Southern India was specially impressed with the singular beauty of those trees. White toon trees, on the other hand, planted out amidst gums, casuarinas and grevilleas, are not yet two feet high, while the others are from 5 to 10 feet. We also know that the red wood of *cedrela toona* is little if at all inferior to mahogany in value. "One of the most important of all timber trees for furniture wood, which is easily worked, light, seasons readily, takes polish well and is applicable for a multitude of purposes in joinery. Dr. Brandis gives the stem girth of trees 35 years old at 7 feet, when the tree grew on rich and moist soil; trees with 30 feet circumference are known." Such is the summing-up of Baron von Mueller. Added to all this the bark is very astringent and has been found valuable in fevers, dysentery, &c. Lindley's "Flora Medica" states that the bark of *cedrela toona* is "a powerful astringent, and though not bitter a tolerably good substitute for Peruvian bark in the cure of remitting and intermitting fevers; particularly when joined with a small portion of the powdered seed of *Casalpinia Bonducella* (Kutulegee of the Bengalese) which is a most powerful bitter. Roxb. The bark was used in Java by Dr. Blume, with much success in the worst epidemic fevers, diarrhoea, and other complaints. Horsfield also applies it in various cases of dysentery but in the last stage, when the inflammatory symptoms had disappeared. Forster considers it especially useful in bilious fevers, and inveterate diarrhoea arising from atony of the muscular fibre." I notice that they have a white cedar in Australia, *Melia australis*. In a garden in Melbourne, I saw what we call in Ceylon the Indian or Persian lilac, and my hosts called it "white cedar." The white toon, the seed of which has come to Ceylon from Southern India, may possibly be a good tree at low altitudes, but here it is simply a great disappointment.

Pending a fuller communication, Dr. Trimen now writes to say that the tree which the planters have named "white toon" is the typical *Cedrela toona* of the "Flora Indica," the red toon being a variety indigenous to elevated parts of India, distinguished as *Cedrela serrata*! The "white toon" yields beautiful red wood! It is, therefore, more than probable that this "white toon" as we have named it, though it is not at home up in these higher altitudes, may prove to be a very valuable acquisi-

* This question we cannot decide; and it is curious that in the district of Salem, whence we got the white toon seed from the forester, *Cedrela toona* is said to abound in the jungle. The late Dr. Shortt classed "red Cedar" white Cedar, *Chickrassia tabularis* and *Cedrela toona* together.

tion from 3,000 or 3,500 feet downwards. I will write fully on this interesting subject when I hear further from Dr. Trimen. Meantime I owe an apology to the real Simon Pure—the true *Cedrela toona*—for degrading it into a mere variety.

NANUOYA, April 22.

No further communication having reached me from Dr. Trimen respecting *Cedrela toona*, I feel bound to take it for granted that the receipt and examination of the specimens we sent him both of the red and the so-called "white toon" have but confirmed the conclusions announced in the letter he sent in response to our descriptions of the two, viz. that what we in Ceylon have called "white toon" is the typical *Cedrela toona*, and that it is the red which must be relegated to the rank of a mere variety, as *C. toona* VAR. *serulata* or *serrata*. It is rather curious that I should have lost sight of this distinction; for I find that in writing on the subject in Feb. 1882 I quoted the article on the TOON from Bal-four's Timber Trees, including a note by Dr. J. L. Stewart on *Cedrela toona* VAR. *serrata*, which stated:—"The leaves of this are always saw-edged (serrated) in which alone it differs from *C. toona*, ROXB. Its wood is often red, but is of more open texture and LIGHTER in colour than *C. toona*, and stands water well. In Kanawar it is used for bridges, and in some places the hoops of sieves are made from it. The wood has a foetid smell when fresh: an ordinary leaf is 30 inches long." So far Dr. Stewart, and it is a surprise to hear that the wood of "the red toon" *par excellence* is lighter in colour than that of *Cedrela toona*, which, in calling "white" from its foliage, we naturally inferred would yield white, and therefore inferior, timber. But let me now proceed to quote Dr. Trimen's letter, which I do, feeling assured that it is his desire that the exact truth about a matter so interesting should be known:—

Peradeniya, April 16th.

I am so much obliged to you for all the information about "White Toona." I never before knew to what plant it was referred.

As to the botanical names, there can be no doubt that this "White Toon" is the real *Cedrela Toona* as described by Roxburgh and all subsequent writers, and figured by Wight, Brandis and Beddome under that name. It grows wild in Bengal, Sikkim, &c.; and is the only sort in Southern India. We have a large old tree in the garden here, received from Calcutta in 1850, which flowers every year but does not seed. The wood is beautiful, light, pale red, even and very sweet scented, as I know having had to cut off several large branches from our old tree a few years ago.

Now as to the "Red Toon." There is something to be said for your view, that this is distinct from the other, and were I writing on these plants I should give it at least the rank of a variety, as I have done in the catalogue of this garden, p. 17. But in the "Flora of British India," it is not accorded even that rank. However, it has a name and it will be well to use it. It was named *Cedrela serrulata* by Royle in his Botany of the Himalayas, and that is the name that should be adopted. It grows wild only in the N.-W. Himalaya, and I think the first trees seen in Ceylon were those on Looiecondra obtained by Mr. Taylor. Ours in the Gardens came from that source, but I do not know whence Taylor got them.

The seeds have the large wing at one end only. I fancy the seed of the "white" kind (true *Cedrela Toona*) has the wing at both ends; but I have never seen it, judging only from the pictures. This may be a guide in purchasing.

If you have any seed left of your "white toon" you might compare it with the enclosed "red" seed.

Your specimens have not yet arrived, but I thought I had better write at once to let you know clearly

the botanical facts of the case. If anything further is suggested by them I will write again.

We have no seed of what we regarded as "white toon" left, but Mr. John Fraser, of Abbotsford estate who had the sowing of it, states that "it was much smaller and lighter than that sent by Dr. Trimen, (the red toon seed) and I think the seeds were winged at both ends, but being of very fragile stuff the wings are usually mostly broken. The seed now sent is undoubtedly that of the red toon or serrated variety." What Dr. Trimen says of the timber of the "white toon" of the Ceylon planters, that is the true *Cedrela toona*, is most important and the only questions now to be settled are the altitude up to which the tree will feel at home in Ceylon and whether at such altitude, (say from 3,500 to sea level,) it can be protected from the insects which so seriously injure the trees in our higher altitudes here and even in Maskeliya at about 4,000 feet. Being the only kind indigenous in Southern India, it surely must grow to high elevations there; and if it flourishes in Mysore up to 4,000 feet it ought to do well with us up to 5,000. We shall give those trees we have planted out the chance of showing what they can do, but what to do with about 200,000 in our nurseries is the question. I shall send an advertisement with this communication, offering the plants at prices which will not reimburse us for our expense and trouble, so that any inclined to try the experiment may be able cheaply to do so. As Mr. James Taylor most probably brought the seed from Darjiling, his toons which were attacked by insects in Hewaheta were, I suspect, red toons? All I can say, if so, is that in Dimbula and Nuwara Eliya we have that variety flourishing wonderfully at from 4,700 to 6,400 feet and that for 11 years no insect has attacked them. The tree is deciduous, and so, at certain seasons of the year, the great leaves or branchlets turn yellow and fall off, giving the trees for a time a "shuck" appearance, but generally, nothing can be more luxuriant than the deep red foliage on the tops of the tall, straight stems.

THE NORMAL AREA under wheat cultivation in India is now 26 million acres with an out-turn of 7 millions tons of which a little less than one-sixth is exported.—*M. Times*.

THE ANTHRACITE coal trade is looking up again in America. The reduction in the output for this year up to March 29th is as much as 668,332 tons, and this has had a good effect on prices. Good news this for Philadelphia and Reading stockholders.—*O. Mail*, April 25th.

"WHAT TO EAT, AND HOW TO COOK IT," is the title of a useful little pamphlet published annually in connection with the "Apple-Tree" Vegetarian Restaurants. The copy before us contains many most appetising receipts, while some of the substitutes for the forbidden suet or dripping are very ingenious. We are told that, instead of the former, vegetarians can sop bread-crumbs in butter or oil, or add "a little crushed and soaked Tapioca to the paste used for boiled puddings." Is it prejudice alone which makes us disinclined to change our own tried receipt for a Christmas pudding for one, in which, although the ingredients altogether weigh rather less than 6 lb., is yet to contain 1 lb. of mashed Potatoes, or 8 oz. of mashed Carrots? How do vegetarians reconcile the eating of eggs with their resolution to destroy no animal life for food? In spite of all we have said, we can only repeat at the end of this notice the words we said at the beginning—many of the recipes are excellent, and likely to be useful to many besides those for whom they are more especially intended.—*Gardeners' Chronicle*.

ROYAL BOTANIC GARDENS, PERADENIYA,
CEYLON, IN 1888 AND SUCCEEDING YEARS.

(From Official Records.)

(Continued from page 809.)

To His Excellency the Rt. Hon'ble the GOVERNOR, Sir,—I have the honor to acknowledge the receipt of Your Excellency's letter with its enclosure of the 4th instant, and am truly grateful for the compassionate feeling which it expresses for my illness.

The fine climate however of Nuwera Eliya in so short a time, added to the exceeding great kindness of your excellent lady, Mrs. S. Mackenzie, has done wonders to assist the safe recovery I have now nearly experienced. I feel sufficiently strong, though perhaps anxiety may excite it a little, to return to Peradenia, which I purpose to do on the 8th, to arrive on the 10th instant, and when there my utmost careful attention shall be paid to secure to the China and other plants the success Your Excellency has been pleased to calculate upon. The list of those from China contains many that we have at Peradenia, as the *Dimocarpus*, *Cookia*, *Mespilus*, *Gardenia*, *Diospyrus*, *Ixora*, *Myrtus*, *Olea*, *Camellia*, *Magnolia*, &c., but the varieties of them and those plants not hereinserted will prove a great acquisition to the Colony. The vines are particularly well-selected, but the list of them does not contain the 4 other fruit trees as specified by Your Excellency.

This box with the 4 others if pleasing to Your Excellency would be better sent up to Peradenia as early as possible, a nursing attention being of such essential service to plants, after a long passage to a foreign climate, and that immediate if practicable. Whatever plants Your Excellency would wish to be returned to Europe, in the glazed case, shall be immediately prepared when the list is furnished to me. Being aware that Your Excellency is unattended by an Aide-de-camp in Colombo, I humbly beg to be pardoned the assurance of addressing this to my last letter direct to Your Excellency.

I have the Honor to be, Sir, Your Excellency's most obedient humble Servant,

J. G. LEAR.

Nuwera Eliya, 7th, April 1839.

His Excellency the Rt. Hon'ble the GOVERNOR, Sir,—I have the Honor most humbly to request that Your Excellency will be pleased to allow the accompanying petition of Mr. Solomonsz to have some weight in his favour with Your Excellency's Government.

The present situation of Mr. S. with a large family, however merited it may be, renders him an object that lays claim to the feelings of human generosity and kindness.

I have the Honor to be, Sir, Your Excellency's most obedient Servant,

J. G. LEAR.

Royal Botanic Garden, 19th April 1839.

His Excellency the Rt. Hon'ble the GOVERNOR.

Sir,—I have the Honor to acknowledge the receipt of Your Excellency's letter of the 16th instant with its enclosures and one box of seeds quite safe, respecting which I will pay the greatest attention to Your Excellency's commands. The collection contains a few packets not inserted in the list, which I will add to it for Your Excellency's information, and for which purpose, I beg Your Excellency will be pleased to allow me to keep it with the letter until next tappel. I also beg to inform Your Excellency that the 4 cases of

China plants, and 1 from the Horticultural Society arrived in good order last evening (as far as carriage goes).

The plants in the China cases, I am sorry are much injured, and I fear the major part of them are dead; those in the case from the Horticultural Society have also suffered; the case had not screws sufficient in the framework of glass; and the heat has warped it a little in several places; the air has consequently had access to the plants much to their injury. *Eleven* only of the *eighteen* vines are living, and those are very weak, *three* of the *four* other fruit trees are also dead. The Kei apple from S. Africa is the one surviving.

The whole of the above must remain a day or two in the cases before removal, when I hope to have the honor of forwarding to Your Excellency a more detailed account of their quality and condition.

I have the Honor to be, Sir, Your Excellency's very humble and obedient Servant,

J. G. LEAR.

Royal Botanic Garden, 19th April 1839.

His Excellency the Rt. Hon'ble the GOVERNOR.

Sir,—I have the honor to enclose herewith for Your Excellency the letter and list from Doctor Lindley. A copy of the list is made agreeable to Your Excellency's directions to be kept until required. With respect to the collection of seeds, I have the honor to inform Your Excellency that upon examination there appears to me no *very urgent* reason for any portion of these being sown at any other place than Peradenia, though there is particular care required in watching such seeds during the process of vegetation, a moderately high temperature during that period is not an objection but often of great assistance; it would still be necessary to move many of the plants to Nuwera Eliya, when vegetation is completed, to have a nursing care in the more congenial air of that place, and a selection shall be made accordingly, but it is highly to be wished that a person should take them in charge, who would feel interested in their well doing and pay more attention to them, than the generality of people on this island would feel inclined to bestow. It is a want of spirit of this nature that the more forcibly induces me to keep the whole collection under my own eye for the present, until they are more fit to bear indifferent usage, otherwise to give them the fairest *possible chance*. I should like to try a *few* at Nuwera Eliya; and with Your Excellency's permission, if I may be allowed to proceed occasionally there, as the different stages of the plants would require me, I will still reserve a few for that purpose, and perhaps a soldier could be found and permitted to attend to them punctually by my directions. Should this suggestion meet the approval of Your Excellency, I will immediately proceed to its adoption while every other command from Your Excellency shall have my best constant attention.

I have the honor to be, Sir, Your Excellency's very humble and obedient Servant,

J. G. LEAR.

Royal Botanic Garden, 20th April 1839.

His Excellency the Rt. Hon'ble the GOVERNOR.

Sir,—I have the Honor to forward to Your Excellency's address per this day's tappel the Gourd, Melon seeds &c. as directed by Your Excellency's letter of the 19th instant, which I hope will arrive in good condition.

I have the honor to be, Sir, Your Excellency's most obedient humble Servant,

J. G. LEAR.

Royal Botanic Garden, 21st April 1839.

His Excellency the Rt. Hon'ble the GOVERNOR, &c., &c., &c.

Sir,—I have the honor to enclose herewith agreeable to Your Excellency's directions two separate reports on the condition of the plants received from China and England, having finally examined and removed them from the cases in which they were contained. I was sorry to find them in such a bad state, particularly those from China. The circumstance of the plants which are noticed in the columns of the said report having *lived* in the cases since January, and now to be in condition clearly proves that although they received great injury on the way; they were not much assisted by experienced attention at Galle. Had they been sent to the Royal Botanic Gardens immediately on their arrival there, better hopes than now might have been entertained of a greater number, it being upon all occasions necessary to remove plants from *confined* cases, as early as possible, the soil contained therein becoming after a certain time inactive, sour and pernicious to vegetation; but the utmost energy shall not be spared in my endeavour to recover those that still have life.

I have the honor to be, Sir, Your Excellency's most obedient humble Servant,

J. G. LEAR.

Royal Botanic Garden, Peradenia, 26th April 1839.

A Report on the Condition of the Plants contained in 4 cases from China for the information of His Excellency the Rt. Hon'ble the GOVERNOR. —Received at Peradenia, 16th April, 1839.

J. G. LEAR

Actg. Supdt.

Royal Botanic Garden, Peradenia, 25th April 1839.

The soil containing the above plants was too much of a description approaching to *clay* than otherwise, but its being retentive of moisture was well adapted to the *package* of plants from *China* but not to their *growth*; they appeared to have been constantly saturated with water, on their voyage or since—a system that could not prove otherwise than injurious. (particularly in the above description of soil) to the health of the plants. With the exception of the 17 annexed, the roots of the whole were more or less decayed and rotten and but few can be reasonably supposed to survive the injury produced thereby.

J. G. LEAR,

Actg. Supdt.

Royal Botanic Garden, Peradenia, Ceylon, 26th April 1839.

His Excellency the Rt. Hon'ble the GOVERNOR. Sir,—In reference to your Excellency's enquiry of the 3rd inst., respecting the London Vines and Melon seeds, I have the honor to state for your Excellency's information that the former which I have previously the honor to report alive are still doing

well and under process of propagation; but of the latter none have vegetated except the Smyrna Melon, which did so freely, but through a long continuance of wet weather to which they have been unavoidably exposed are nearly all damped off. The fruit of the fine Green-fleshed Melon from seeds previously supplied me by your Excellency, and which were nearly at maturity, I am sorry to add have also rotted from the same cause; as respects the other fruits and flower seeds from the Horticultural Society of London which were sown in the latter part of April. None of the former have yet vegetated and very few of the latter, but as a sufficient time has not yet been allowed to them all for that purpose (particularly for the stone fruit) I hope to have the honor of forwarding to Your Excellency, a more particular and detailed account, when the period necessary for them shall have elapsed.

I have the honor to be Sir, Your Excellency's Most Humble and Obedient servant,

J. G. LEAR.

Royal Botanic Garden July 8th, 1839.

His Excellency the Rt. Hon'ble the GOVERNOR &c., &c., &c.

Mr. Lear in answer to His Excellency the Rt. Hon'ble the Governor's letter of last evening has the honor to inform His Excellency that however much he regrets the loss of His Excellency's horse, and however hurtful to his feelings it must be to be accused of ill-usage towards him, he has the most conscientious satisfaction of not deserving it, and trusts that His Excellency on investigating the matter will be apprised of that and be led to form a conclusion more lenient to him, (Mr. L.)

Royal Botanic Garden, 16th June, 1839.

His Excellency the Rt. Hon'ble the GOVERNOR, Sir,—Permit me to offer you my very grateful acknowledgements for the means of instruction, which you have been pleased to honor me with in the very interesting and valuable papers on the subject of Cinnamon and Cassia, of which I will take great care and return safely with "the copy" (when completed) which you were pleased to call for.

I have the honor to be, Sir, your most obedient humble servant,

J. G. LEAR.

Royal Botanic Gardens, 2nd July, 1839.

Mr. Lear has the honor to acknowledge the receipt of His Excellency the Rt. Hon'ble the Governor's "box and parcel of seeds," to which he will pay the greatest attention agreeably to His Excellency's commands. He has also the honor to state for His Excellency's information that the American seeds previously received from His Excellency prove themselves to have been of fine quality and well preserved; they have vegetated better than any Mr. Lear has hitherto seen in Ceylon. Mr. Lear is firmly of opinion that seeds should leave England in the autumn, as early as possible after they are well ripe and harvested, being when quite fresh better able to resist the frequent changes of temperature to which they are necessarily exposed; they should also be without a mixture of the previous year's collecting, a practice in which many seedsmen are given to indulge. This may be borne in England with tolerable results, but will not answer for exportation. To this Mr. Lear attributes failure in many cases,—a month or two is also gamed in the age of the seeds by shipping early which is of great consequence to some kinds; but whilst a few months would determine the existence of vitality in some kinds, on others it would have but little effect, and Mr.

Lear thinks upon the whole that His Excellency's fine assortment will be but little hurt. Season does certainly very much influence the success of seeds generally, but it varies as seeds happen to be the produce of countries equal or opposed in this respect. This monsoon has been very favourable to the American seeds.

Royal Botanic Garden, Peradenia, 29th July, 1839.

Mr. Lear has the honor to forward by the bearer for His Excellency the Rt. Hon'ble the Governor the Cucumber and Melon seeds agreeably to His Excellency's instructions of yesterday, and to state that he will report the result of the remainder in due season for His Excellency's information.

Royal Botanic Garden, 31st July, 1839.

His Excellency the Rt. Hon'ble the GOVERNOR, Sir,—I have the honor to acknowledge the receipt of Your Excellency's letter of yesterday's date with its enclosures from Mr. Dyke, and am delighted to find that that gentleman has been successful in ripening the "Smyrna Melon" as it gives great hopes that with other and perhaps more esteemed kinds he may be equally so, at a future period, I have availed myself of Your Excellency's kindness to retain a portion of the seeds* from Mr. Dyke, they will greatly assist me in forming my conclusion (which I hope to be able eventually to do) as to the best seasons for their cultivation here. There has been of late so much wet that plants of these succulent and tender nature could not reasonably be expected to arrive at much perfection. Mine have constantly been rotting off and disappointing all my efforts to prevent them, hitherto, with the exception of the "water melon," one of which I have grown to a very large size and tolerably well flavoured, but during the next monsoon I hope to have better results. Your Excellency's instructions respecting Melon Seeds for Mr. Dyke with my attendance upon Your Excellency at the Pavilion shall receive my particular and early duty.

Most sincerely hoping that Your Excellency has thoroughly recovered from your late severe indisposition.

I have the honor to be, Sir, Your Excellency's most faithful and obedient Servant,

J. G. LEAR.

Royal Botanic Gardens, Aug. 30th 1839.

(To be continued.)

"THE TEMPERANCE BUDGET."

AN INTERVIEW WITH A TEA BROKER.

Calling this morning upon Messrs. Gow, Wilson, and Stanton, of 16, Roodlane, a representative of the *Pall Mall Gazette* found Mr. Wilson and Mr. Davis hard at work arguing *pro* and *con.* on the possible advantages or otherwise which will follow the reduction in the tea due:—

"We have not yet made up our minds," said Mr. Wilson, "we don't yet know whether this reduction will ultimately benefit the Indian and Ceylon or the China markets. My partner, Mr. Davis, thinks the former will have the benefit. The fact is that the duty on cheap teas has been proportionately much higher than on dear teas. The market prices of teas, apart from the duty, have been averaging on Ceylon teas about eleven pence, on India teas tenpence, and China teas sevenpence per lb. Now the sixpenny duty was consequently nearly 100 per cent. on the China teas, whereas it was only 50 per cent. on India and Ceylon teas. The question now is—will the reduction of the duty by making the cheap tea cheaper cause a greater consumption of them.

"I don't believe it will," said Mr. Davis, "the public has by this time been educated to the taste of the better

* The remainder I have the honor herewith to enclose

teas, and as they will also be reduced in price, my argument is that the public will continue to purchase them in preference to buying a bad article simply because it is cheaper. The consumption of China teas has been gradually decreasing for the past ten years, and I believe it will go on until China tea is right out of the market.

"The immediate result on the market this morning," said Mr. Wilson, "is that cheap teas have gone up in price, on account of the anticipated run upon them. * But again the question arises, will that increase continue. That cannot now be decided of course. Indeed there can be no decided opinion given."

"How will it affect the middleman?" asked our representative.

"Well," said Mr. Davis, "there are few middlemen nowadays. Mr. Goschen has really struck a blow at the small grocer, while he has done a great deal of good to the large retail dealers like Cooper, Cooper and Company and others. The profits on tea are nothing like so great as they were some years ago. The telegraph and the rapid means of conveyance have rendered the passage of tea from the grower to consumer so much easier that the old-fashioned profits exist no longer, or only in small degree."

"The question of whether the consumer will benefit by the reduction is one I cannot answer yet," said Mr. Wilson. "It is dependent upon the result on the market. Still I know of a tea dealer who has been preparing for the reduction, and no doubt the grocers will this very day be plastering their windows with placards, 'All my tea reduced 2d in the pound. But then the question of blending comes in.'"

"I know a very large dealer," said Mr. Davis, "who for a couple of months past has been preparing for the reduction, and who told me that directly it came he would be prepared to sell his teas to his customers at three-pence less in the pound, and that he would not use a particle of China tea. But really it will be twelve months before the actual results can be thoroughly realized.—*P. M. Gazette*, April 18th.

THE FUTURE OF JAVA.

TO THE EDITOR OF THE "MELBOURNE LEADER."

SIR,—I noticed a few days ago in the "town talk" of a daily contemporary the following, thus:—"Whenever Java falls to that Power (Germany) through the declension or absorption of Holland," &c. Taking the above as my text, may I say a few words. Well, Sir, about four years ago I travelled through much of Java for about four months shooting (an account of the trip appeared with your kind permission in the columns of *The Leader* of the time), and met "all sorts and conditions of men." We (I had a chum) mixed a good deal with the Dutch. At that time the English and colonial papers speculated much on a probable German advance on Holland, and we very frequently asked our Dutch acquaintances what they intended doing in such a case. The invariable and emphatic answer was—*the moment we hear of any advance on Holland we offer Java to Melbourne, Sydney, and Brisbane*. This from officers of rank, from planters from high Government officials, one planter naively remarking, "I pray God every night to let the English rule in Java." Once, while sleeping in a native town, we were roused at midnight by the "chamah" (native chief) at imminent risk to his own life from our loaded revolvers (if he only knew it), to ask mysteriously and eagerly when were we Englishers returning to rule in Java. We have waited long, he said, for you and he seemed much disappointed we were unable to tell him. The Hollanders wanted to know in their turn what we colonials would do when the offer was made. As a good Victorian I always answered, accept of course, but will we accept? I am as certain as a man can be of anything in the future, the offer will be made sooner or later; in fact 'twas hinted the Governor-General had already his instructions how to act in such a contingency. We were much surprised at the dislike (to use no harsher term) shown by the Dutch to their German cousins. What will we Australasians do? will we follow the recent and Gladstonian policy of "scot and scuttle," vide Oandahar,

the Soudan, New Guinea and Samoa, a policy so un-English and suicidal that we outsiders stand amazed and aghast at a great nation with such a glorious previous record tolerating it for a moment. May we (to paraphrase the Laureate)

Pray God our greatness may not fail,

Through craven fears of being great.

Let our rulers look to it, may they "take occasion by the hand and make our bounds of empire greater yet," or assuredly they will be offered the opportunity. Enclosing card and apologising in advance for space occupied.—Yours, &c.,

ANGLO-AUSTRAL,

Drysdale, March 8th.

PLANTING REPORT FROM THE HILLS OF CEYLON:

A TRIP TO NUWARA ELIYA AND HAKGALA—THE BEAUTIES OF THE GARDENS—FINE AND QUICKGROWING TIMBER TREES—EUROPEAN FRUIT TREES.

NANUOTA, May 3rd.

Yesterday was a perfect day for a trip to Nuwara Eliya and Hakgala: rainless but not glaringly sunny. The temperature was genial and even as day was closing and a south-west breeze blowing as we returned from the Gardens to the Plain, the cold was only bracing. We admired the effect of the climate on a child who had been up only a few weeks, but whose cheeks were becoming pink in lieu of the white of Colombo. And how delicious some fine Colombo mangoes tasted, after a night in the cold temperature! Although there was not much vivid colouring in the forests below Nuwara Eliya, the various shades of green, from very dark to very light had a beautiful effect, and as we neared the Sanatorium and passed through and out of it, we saw abundance of brilliant colours in combination and contrast, in the large crimson clusters on the rhododendrons and the differing shades of yellow of the truly splendid furze (gorse) and the golden wattle: Ceylon, Europe and Australia florally represented. But what shall we say of the carpets of bright colours at Hakgalla, especially the pinks of such varied forms and hues, some equal to finest carnations. Then there was the daisy tree, and the begonias, the lilies and the irises, the fernery and the turfed banks and open spaces, the water lilies, the plantain of Abyssinia, the flame tree of Australia, the handsome *pinus longifolia* of the Himalayas, the aurocarias, cypresses, junipers and frenelas. Mr. Nock told us much of interest which we need not repeat, as we hope soon to see it in full detail in Dr. Trimen's report. Those tubers of the nature of potatoes which were not at first favourably reported on are, under Mr. Nock's careful cultivation, increasing very considerably in size and improving much in quality. The natives have taken greatly to them. We were however specially interested in seeing, in a utilized shape, the timber of two trees which promise to be valuable additions to our forest resources in Ceylon: *Cupressus torulosa* and *Cryptomeria japonica* "the Japan cedar." The timber of the former reminded me a good deal of that of the celebrated Huon pine of Tasmania, while the cryptomeria wood resembled that of the best quality of fir or spruce deals. *Cryptomeria japonica* is making growth only second to that of the red toons at Nuwara Eliya, the progress of the latter being quite phenomenal, although the tops of a few exposed to the south-west monsoon had suffered. A cryptomeria occasionally puts on cones prematurely, but I do not suppose this is of much importance. I ought not to forget the European fruit trees,—apples, cherries, peaches, plums,—at Hakgalla. They have not flourished quite as could be wished, but successive introductions, at different periods of the year, may lead to large and permanent success.

The man who wagered he would throw another across the Mississippi pleaded that he did not expect to be successful with the first throw. Oranges, peaches, plums and baking pears are already great successes on the mountains of Ceylon, and the turn of apples, dessert pears, cherries, &c., may be not far distant. We met several parties at or going to the mountain gardens, which repose beneath the sphinx-like rock, and recognized Mr. Cull of the Royal College, striding down at the rate of at least 5 miles an hour. As we entered the Plain, on our return, an hour before sunset, we were met by a gratefully cool south-west breeze. We felt it here this morning, as well as the specially dense mist it carried on its wings and which ended in a light shower (minus thunder,) at about 2 o'clock. It soon ended, however, and the afternoon and evening have been beautiful.

May 4th—rises calm and hazy, promising a hot day and perhaps a shower in the course of it.

SELF-COLONIZATION OF THE COCONUT PALM.

With reference to Mr. Hemsley's note on this subject to *Nature* (p. 537), I regret to have to inform him that the two young palms found on Falcon Island were placed there by a Tongan chief of Namuka, who, in 1887, had the curiosity to visit the newly-born island, and took some coconuts with him. This information I received from Commander Oldham, who had been much interested at finding these sprouting nuts at some 12 feet above sea-level and well in from the shore of the island, but who found out the unexpected facts in time to save me from making a speculation somewhat similar to Mr. Hemsley's. W. J. L. WHARTON.

—*Nature*, April 24th.

GEM MINING PROSPECTS IN BURMA:

ABOLITION OF SMUGGLING AT THE MINES—NATIVE MINERS
AND FINDS—THE PROGRESS IN 12 MONTHS—NATIVE
HYDRAULIC WORK.

(Continued.)

Under such circumstances there need be no difficulty in understanding how likely it is that very extensive smuggling is carried on, not only by the men actually engaged in the gempits, but also by the licensees who keep out of view the more valuable finds and dispose of them on their own account.

Here is the opinion of a Shan trader who formerly worked in these mines and traded largely in rubies during the king's time, and has spent all his life in the district except when visiting Mandalay and Rangoon, and for about nine months on a visit to the Bangkok sapphire mines:—"Big rubies are found still just as they used to be in the king's time, but the 'bo' who went up to purchase offered such a small price, only about one-fifth of what the king used to give, that the miners became alarmed, and now often conceal valuable stones, selling them privately elsewhere. Stones are easily concealed, and as long as the value is large—and the monopolist refuses to give generous prices for them, smuggling will go on, when it is known the price in the market is much higher than it used to be. The English officials do all they can to assist the ruby mine monopolists in preventing smuggling. A man was thought to have secreted a number of stones and was ordered not to leave the district and was

watched for some days. He did not leave by the ordinary route but got away one night by the jungle path and was not missed until he had been gone a long time. The English do not punish the wife and children of offenders as they would have been punished in the Burmese time and people are not so afraid of smuggling. The company must arrange with the miners to prevent it. I cannot say how honesty can be brought about amongst the miners, but if they are treated well they may become honest. When the first *bo* went up they showed him all the stones they got, big and little, but he offered so small a sum that they got disgusted and now they usually conceal the big rubies and only show those of less value."

These are the expressed opinions of a native of the country, and of themselves bear testimony to the correctness of a general suspicion that as yet the Company have failed in attempting to obtain the more valuable stones which are found on their concession. From what was told us by Sir Lepel Griffin it will be seen that a very short time spent at the ruby mines enabled him to grasp the situation—and with a promptness of action observable in the lives of our best men in India he acted on his convictions and exercised without hesitation the powers conferred upon him by the directors in London. He has once for all abolished smuggling at the mines as an offence by doing away with the obligation to refer all finds of stones to the Company; the licensees are at liberty to do as they like with the gems they find, and consequently their taking away the stones is no longer smuggling. The act remains, but the offence disappears. These are his own words in regard to this matter:—"I am very glad to find that the papers here and the opinion of the people I have spoken to are in agreement with what I decided to do very shortly after I reached Mogok, in abolishing entirely the rules for the prevention of smuggling. It is a matter of exceeding importance. At the present time the native licensed miners are naturally in a state of hostility to the Company. They must be so no doubt, and they do not bring us the rubies they find at our mines at all, but only rubbish. The large rubies they do not bring us. In the first place their feelings are not particularly friendly towards us, and in the second place smuggling is so easy that they can sell rubies for very nearly the real price without the reduction of thirty per cent which they would have to pay if we decline to take them, or if they sold them for other people. So, with the entire approval of the Government and the local authorities and the Financial Commissioner, and everyone who seems to have any sense in his head, I abolished this system altogether. The market for the sale of rubies will now be quite free; there is nothing to prevent them from bringing us their best rubies for preferential sale. At the same time they will pay us from one and a half to two lakhs of rupees a year for the privilege of being allowed to sell the rubies where they like. These native miners must make a great deal of money and of course it would be better for us to abolish native mining altogether so that we could entirely stop smuggling. I mean the licensees who have the hereditary right of working—but that cannot be done without a great amount of friction and irritation, which would embarrass the Government and impede the Company. We cannot work with all the people of the country against us so we thought the next best thing would be to give them a free hand and abolish smuggling in this way, because unless we can abolish it we cannot make our mines pay. I may tell you we have not increased the number of native miners. A list is

kept of the men allowed to work, so practically we are not in any way worse off than before. From my point of view I can see we are in an infinitely better position and are making at least a couple of lakhs which we lost before. By this arrangement they need not send their rubies to the treasury at Mandalay for sale, all that is now abolished. The Indian and local Governments have waived their rights in favour of the Company." From this we learn that the native miners have been found willing to pay, and pay heavily too, for liberty of action as regards sale of the gems. One and a half to two lakhs of rupees per annum is no small sum either for the miners to pay or the Company to receive. We learn the arrangement is to last a year as a tentative measure, and that its adoption will do away with the necessity for the guard of Gorkha police and this again will be a saving of some R2,000 rupees a month, no small item in the annual cost of working the establishment at Mogok.

When we come to the question of what the agents and employees have done during the twelve months that have elapsed since they ostensibly commenced operations in Burmah. We find it would be easier to state what has been left undone rather than what has been done. The impression left on the mind after an interview with the executive engineer is that "but little can be said of what is being done on the property, the actual work of searching for gems can hardly be said to have fairly commenced. What has been effected in spite of a host of difficulties has necessarily been more a work of preparation than anything else. It is not easy for the outside public or the shareholders in so large an undertaking, to realise the immense difficulties under which it must of necessity be carried out." These of course are mere indefinite observations from the guarded statements of an employee who was only doing his duty to his employers in keeping a guard over his tongue when asked for information. Sir Lepel Griffin throws a little more light on the subject:—"As to the work we have done, I may say we have not gone very far. The machinery is coming up and I am urging things on as fast as possible. I have relieved the Chief Engineer of all duty as superintendent because I saw he would be overburdened. With all the miscellaneous work he had not time to attend to his proper duties, but now he is quite free to go on with his engineering and ruby mining. Mr. Atlay will take over the duties of superintendent. He is agent now and he will have sole control of everybody except the engineering work, which is quite enough for one man and is after all the most important post. Mr. Brigham came from California six months ago, but I do not think there is work for him. He has suffered exceedingly in health and is anxious to leave, so I have consented to his going. I do not think he has enough scope for hydraulic engineering of the type they use in California, which is also a very expensive one. *I think the native method almost as good.*"

Knowing as we do the contemptuous terms in which Mr. Streeter ridiculed the native gem pits in Ceylon, we should like to hear what he has to say to the Chairman of his famous Burma Company, stating as his opinion that it is "almost as good as" the costly and scientific hydraulic engineering with which mining is so largely conducted in the State of California. This by way of parenthesis. From the above utterances of Sir Lepel Griffin we may very fairly infer that he is not altogether satisfied with what has been done at Mogok. Expensive men had been engaged when there was nothing for them to do, for it must not be forgotten that Mr. Brigham

who is now leaving the country without any practical advantage having accrued to the Company by his services, is not the only one who has done so. Mr. Robert Gordon was the engineer who selected the grant and took up his residence upon it. Finding however there was nothing for him to do, he accepted an offer in Siam and is now chief engineer to the Government there. The employment of these men must have cost the Company a very considerable amount for which little or nothing has been obtained in return. Sir Lepel Griffin went on to say:—"I am much pleased at the general aspect of affairs and am particularly convinced that if the work is carried on with energy it will be a great success. I think the difficulties have not been understood as to getting along the road, the amount of sickness and the almost impossibility of getting machinery to the place until two months ago. The road is a ghastly road still. I certainly told the shareholders so as plainly as I could, but I did not know it so well then as I know now. I have, however, greater faith than ever in the prospects of the Company. It wanted, as I have said, to be worked in a more energetic way and I hope this will be done."

Put into as few words as possible this means the past year has been very nearly lost as far as the Company is concerned; it is nobody's fault, but the loss remains, and a great quantity of the Company's capital has been unprofitably squandered. This is from the Chairman of the Company, let us see what the comparatively uncultured Shan trader has to say:—"The officials of the place do not want the truth to get into the newspapers. The machinery sent out from England is scattered all over the district. It is like King Mindohn's iron foundry and cotton mill, one part here and one part four miles off. If these things were reported in newspapers, it is probable that enquiries would be made as to who is responsible for the non-erection of the machinery, or at any rate for not keeping the parts together instead of in confusion, and some of the people at the Ruby Mines might get into trouble. I do not think that working the mines on the present system will ever pay the Company unless they get the Government to reduce the amount of the fee they pay annually for the concession."

SCOTTISH CEYLON TEA COMPANY, LIMITED.

(Special Report.)

The first annual ordinary meeting of the Company was held at the Company's offices, 16 Philpot Lane, London E.C., on the 15th April last at 3 p. m.

Mr. H. L. FORBES, the Chairman of the Company, presided. The notice convening the meeting was read by the Secretaries. On the motion of the Chairman the report of the Directors and accounts for 1889, as submitted, were taken as read.

Mr. FORBES pointed out that little was left for him to add, as the quasi prospectus and the report, now in the hands of the shareholders, gave all information regarding the progress and operations of the Company, but he would add the following remarks: "The first year closed on 31st December 1889, and gave a result of 16½ per cent profit on the 12 months' working. The Board led the shareholders to expect no dividend for past year, but I have now the pleasure to propose to them to divide 4½ per cent. Contrary to the usual practice with new Companies, the whole of the preliminary expenses amounting to £425 11s 8d had been written off. Further a sum of £4,315 10s 2d had been expended on Capital account. These two items, together £4,741 1s 10d, had been

passed to Profit and Loss, and from the balance at credit of this account, £2,014 10s 8d, the proposed dividend would be provided. After payment of dividend and income tax, there will remain only a nominal sum to carry forward to next account. The Directors quite recognize the desirability of establishing a reserve fund, and now that all heavy outlay on capital account has been incurred, the commencement of a reserve will be made on the first opportunity. I would point out that 10 per cent, at least, has been added to the value of the Company's property by the capital expenditure already referred to, and consequently the shares in the Company have increased in value 10 per cent. It is satisfactory alike to vendors of the estates, and to the Company, that while the expenditure comes within £10 of the estimate, the receipts of produce show a very large increase on the estimated quantities. The items of those increases over estimates are tea 34,277 lb., coffee 1,170 bushels and cinchona bark 4,073 lb. I have no wish to prophecy what future results are to be, but I may, at least, state that the position is a thoroughly sound one, and with care and economy in London and Ceylon, if the Scottish Ceylon Tea Company does not pay well in the future, it will be a poor lookout for the now prosperous island of Ceylon. It is fitting, and I may add a pleasure to me, to ask the shareholders to record their thanks to the manager and staff in Ceylon who have the interests of the Company at heart, and who have conducted its affairs with energy, ability, and judgment saying where outlay could be wisely avoided, but omitting no work nor improvements likely to enhance the value of the Company's property, or increase its returns. The shareholders are also indebted to the Secretaries in London for their efforts in the interests of the Company. I will now propose the following resolution:—'That the report and accounts, as presented to the shareholders, be adopted, and that a dividend at the rate of 4½ per cent (free of income tax) be declared and paid on and after this date.' Before putting this resolution, if any shareholder desires further information, I will be glad to answer any query to the best of my power."

Messrs. COOPER and TODD made a few remarks laudatory of the Company's economy in working, and Mr. Todd put some questions as to items of account which were replied to satisfactorily.

The resolution was then seconded by Mr. COOPER and carried unanimously.

The next business of the meeting is to settle the remuneration of the directors for 1890, and any proposal as to this had better come from some shareholder.

Mr. ANDREW proposed and Mr. TODD seconded the following resolution:—"I beg to propose that the remuneration of the directors for the current year be on the following sliding scale to be by them divided among themselves as they think fit in accordance with the Articles of Association of the Company:—

If no dividend, or a dividend of under 4%	£50.
If a dividend of 4% and under 5%	100.
" " of 5% "	150.
" " of 7% "	200.
" " of 8% or over ..	250

which, on being put to the meeting, was carried unanimously.

ELECTION OF AUDITOR.

Mr. JAS. ANDERSON proposed and Mr. COOPER seconded the following:—"That Mr. J. B. Laurie be re-elected auditor for 1890 and that his remuneration be fixed at £10 10s."

On the motion of Mr. COOPER, seconded by Mr. TODD, a vote of thanks to the Chairman and directors was carried by acclamation.

THE EASTERN PRODUCE AND ESTATE COMPANY LIMITED.
COFFEE, CACAO, TEA, CINCHONA, CARDAMOMS.

Directors:—Ralph A. Cameron, Esq., Managing Director. Norman W. Grieve, Esq., C. J. Lindsay Nicholson, Esq., David Reid, Esq., Christopher B. Smith, Esq., Edward Wahab, Esq.

The Directors herewith submit Report and Balance-sheet for the second year's working, ending December 31st 1889.

The profit for the year has amounted to £18,513 14s 10d and, after providing £11,749 13s for payment of Interest on Debentures, and the Preference Share dividend, there remains a balance of £6,764 1s 10d to be carried to Reserve Fund in terms of the Articles of Association. Including the balance of £435 13s 10d placed to this account last year, the Reserve Fund will now amount to £7,199 15s 8d. As the Shareholders are aware, the profits of the Company must be applied to the further increase of this Reserve Fund until it reaches £10,000, and thereafter to the annual redemption of £3,000 of the Debenture debt before a dividend can be paid on the Ordinary Shares, such dividend then not to exceed 3 per cent. per annum, until the Debentures are reduced below £50,000. A favourable season for coffee in 1889 which has resulted in a better yield of crop, as compared with the previous year, from the limited area of the Company's properties remaining under this cultivation, coupled with the high prices ruling for this article, has been a material assistance to the year's profits. As exhibited in the schedule annexed, the Company has 9,306 acres under tea cultivation, of which about 4,700 acres are over four years old. About 190 acres more are being planted during the current year. The yield of tea in 1889 was 1,108,000 lb., and the average gross price obtained, including purchased leaf, was 1½d per lb. The crop for 1890 is estimated at 1,365,000 lb. The Shareholders will learn with satisfaction that the liquidators of the Ceylon Company, Limited, with the sanction of the High Court of Chancery, have compromised the long-standing suit with the representatives of the late Mr. R. J. Corbet. The arrangement has not involved any money payment on the part of the liquidators, but it has included the surrender of the mortgaged properties and the Company's undivided half share of Mannickwatte Estate. All legal proceedings, with their attendant risks and expenses, have consequently terminated both in Ceylon and in this country; and the last hindrance being now removed, the completion of the liquidation of the old Company will be carried out without delay.

The Directors regret having to announce the death of their colleague, Mr. Obas. H. Stewart. In accordance with the Articles of Association, two of the Directors, viz., Mr. Nicholson and Mr. Cameron, retire from office, and being eligible offer themselves for re-election. The retiring Auditors' Messrs. Welton, Jones & Co., also offer themselves for re-election. C. J. L. Nicholson, Chairman.

27, CLEMENT'S LANE, Lombard Street, E. C.

INTRODUCING CEYLON TEA INTO AMERICA.

(From the *New York Shipping and Commercial List*. April 1st.)

For several years the tea planters and factors of Ceylon have been endeavoring to create a market for their product, but thus far without success. The failure has been due to two reasons, first, the taste of the vast majority of American tea drinkers has been educated to prefer a leaf that is entirely different both in character and flavor from that grown and prepared in Ceylon or any other part of India, and second, the methods by which these merchants have sought to introduce and popularize their product have been altogether inadequate to accomplish such a result. The consumption of tea in the United States consists chiefly of Japans, China Greens and Formosa Oolong, each of which are delicate in flavor and are what are called light drawing teas, whereas, Ceylon tea makes a heavy bodied dark colored infusion of a strong wirey flavor. There is therefore not a single point of similarity so far as the above varieties of China and Japan teas are concerned. It is quite true that some Congou and Souchong tea are used in this country, but the proportion compared with the consumption of the more distinctive kinds of what may be designated American tea is small. India teas, which include Oeylons, have become deservedly popular in Great Britain as well as in Australia, because they bare a close relationship in character as well as in flavor, to the China Congou that at one time was so largely consumed there, while they furthermore benefited from the persistent and shameful adulteration that John Chinaman resorted to, as he has since learned to his cost. Under these circumstances it is quite evident that any attempt to introduce Ceylon tea in this country is naturally already heavily handicapped and therefore requires greater efforts in every direction if any measure of success is to be accomplished. Tasks equally unpromising have been undertaken, however, with success, but the first requisite is a large sum of money to be spent simply in missionary efforts, and second, peculiar knowledge and experience in directing these efforts in the right channel. The proprietors of any article that has been extensively advertised know what this means and they are well aware of the almost lavish outlay that has been necessary, before the curiosity of consumers had given place to a confirmed habit. The Ceylon tea men have thrown away a good many thousands of dollars in misdirected effort, but their last venture is not only more practical, but promises greater success. They have opened a handsomely furnished tea room on the upper part of Broadway, where they are endeavoring to re-educate the taste of tea-drinkers and thus create a demand for their product. This is in the right direction, but there is not enough of it. There ought to be several such places in every large city in the country, conducted in such a way that they will not only become the town talk, but that every man and woman in the place will be ashamed to admit to friends that they have not used and are not using Ceylon tea. The man who compelled the people to use St. Jacob's oil until he had made a fortune is reported to have spent over one hundred thousand dollars a year in advertising. If the Ceylon tea planters are not prepared to act upon this policy, the sooner they stop where they are the richer they will be.

[There is a deal of sense in the above and the Tea Fund Committee should read, mark, learn and inwardly digest.—*Merchant*.]

THE NEW TEA DUTY.—Messrs. F. S. Long & Co. of Rood Lane append the following "N. B." in red ink to their circular of 18th April, received by the French mail:—

N.B.—The reduction of the Tea Duty from 6d to 4d, which will take effect from 1st May, cannot fail to be a great boon to Ceylon; but we do trust that supplies will not be unduly hurried forward to the detriment of quality. Consumers will take good teas more freely at the reduced price.

CEYLON TEA AND NEW OUTLETS:

THE NEED OF PLANTERS SUPPORTING THE
COLOMBO MARKET IN ORDER TO EN-
COURAGE OUTSIDE ORDERS.*(Communicated.)*

Every one admits the absolute necessity of obtaining outlets for Ceylon tea other than, and in addition to, the London market: but it not so generally recognized that the only way such outside markets can obtain regular supplies of our tea is direct from Colombo. Samples and trial shipments are, of course, often sent from London: and in this way a liking for our teas has been established; but no large or regular business can be carried on for long through London. The reason is plain. The merchant in Canada, Newfoundland, America or elsewhere who buys in London knows very well that his teas have to bear London charges and commissions, which would not be incurred if he bought in Colombo and he naturally concludes that unless he can obtain supplies direct from Ceylon it is not worth while his going in for our teas at all. He may perhaps be content to begin a tentative business by drawing his first supplies from London, but he knows very well that if the trade is to continue he must arrange to import direct from Ceylon. The natural result of the vigorous measures that have been taken to advertize our teas in many lands is seen in the goodly number of orders that have been and are being received in Colombo. All this is very encouraging to those who have the interests of the Ceylon tea industry truly at heart. It remains for those who can sell their teas locally to encourage business with new markets by offering their teas for sale here. The 150,000 lb. or so, which is all that is offered weekly, is quite insufficient to supply even the present demand; and unless the quantity offered be largely increased, extension of trade with markets other than London—which is so essential a matter to the Ceylon tea interest,—cannot possibly be accomplished.

HOW TO PUSH CEYLON TEA AT HOME.

(From a Ceylon Colonist on Furlough.)

London, April 18th.

Ceylon tea is freely advertised everywhere, and Ceylon has a great name for tea, but the good name sells the tea and the shopkeeper in many cases sell the public by supplying other than Ceylon tea. I am pushing sales all I can among Mission centres as well as other places, but Ceylon tea at 1s 5d and even less is freely advertised and sometimes "Ceylon Tea" in large type on the label and "mostly from Ceylon" in very small underneath. The advertising of Ceylon tea is complete; now we want a large Company (all shares taken in Ceylon by Planters and those interested) to sell direct to the Public. There is a grand chance for investors and I will be glad to help all I can.

"BYE PRODUCTS."

COCONUT LEAVES—OLAS.

We should say that there can be but few of our readers who are not acquainted with the very important part which the residuals of various forms of manufacture have lately occupied in the attention of different trading interests at home. These residuals have gradually come to be known under the generic term of 'bye-products,' and as such they were until comparatively recently regarded as waste, their disposal having been a matter of great difficulty in many varied trades. We need only cite as a particularly prominent example

the refuse arising out of the manufacture of coal gas. Many of us will recollect the filthy, iridescent pools which befouled the yards of all gasworks some twenty-five or thirty years back and rendered the neighbourhood of such works almost uninhabitable owing to their unsavory exhalations. Since then all has been changed, and these pools of stinking refuse have been discovered by science to yield the most valuable dyes and the most tasty of artificial flavorings. Nowadays, for nearly everything—even for the decayed cheese of cheesemongers' shops—there has been found a use, the last-mentioned substance (decayed cheese) being the base from which is now extracted the flavoring given to the jargonel pear-drops so dear to the palates of childhood, as well as to the confections delightful to more advanced age!

Apropos to this subject, a correspondent remarks that among the various suggestions we have from lime to lime made in this journal for the extension of what we have generally termed "minor industries" for Ceylon, it may be that we have not given due inclusion to such bye-products as the island may yield. We certainly do not claim for those suggestions that they may always have been of a practicable character, or that our views respecting them have invariably been soundly based. But in the endeavor to open out new methods for the employment of our native population, even the wildest of speculations may sometimes go near to the mark. They may—even if in themselves impossible of realization—give a start to fresh ideas, and therefore it is that we feel we need not when giving publicity to our theories necessarily be confined within narrow limits. On such a ground we venture to think that what has been suggested to us on this subject of bye-products may not prove to be altogether useless. We are referred specially to the leaves of the palmyra and coconut trees, millions of which are annually buried or burned, in some degree certainly as fertilizers, but for the most part in order to get rid of them. Such leaves come undoubtedly within the category of bye-products. They are to a large extent the waste of our coconut and palmyra cultivation.

We believe the late Dr. Ondatje was the first to endeavour in some degree to extend the use of these olas or leaves. He introduced them to the notice of horticulturists in England as affording admirable material for labels for plants, and we believe that such labels have now a wide use throughout Great Britain. But it is further suggested that these leaves furnish a material which, if properly treated here for export, might find an even more extended use. One who has been struck by the large importation of rattans and other canes into England for the purpose of basket weaving, chair-seating and other similar uses, expresses to us, the opinion that the mid-ribs both of the coconut and palmyra leaves might, if properly prepared, compete successfully in the home market for such industries. They would of course have to be split—or rather slit—into the lithe bands required, but this operation would not be one of any particular difficulty. We do not know how far the minor ribs of the serrated leaves which are so largely used here for native broommaking may have been introduced into Europe for similar purposes; but if this has not been attempted, it would certainly seem to us that a useful endeavour might be made in that direction. Perhaps some local correspondents may be able to favour us with information and suggestions on this subject. For it is primarily in the hope that such may be given to us that we have from time to time ventured to put forward our own ideas upon similar topics.

CEYLON UPCOUNTRY PLANTING REPORT:

INFLUENZA EPIDEMIC AND THE SINHALESE HOLIDAYS—SHORTHANDEDNESS ON ESTATES—GOVERNMENT INTERFERENCE WITH COOLY IMMIGRATION AND STOPPAGE OF FERRIES—OPINION OF PLANTERS AS TO THE "SIXTY DAYS" CLAUSE—RUSH OF LEAF AND THE QUALITY OF THE TEA BEING MADE—THE SPRING CACAO CROP—WEATHER.

May 8th.

The Ceylon planters are not likely to forget this sickly season. Most of us are at present worried dreadfully, and work on all hands is falling behind. You hear of men with clearings, unable to do anything to them; of others being so handicapped that coolies for the transport of leaf cannot be had; and in some places the roll of the sick have reached to such magnificent proportions, that the flush is allowed its own sweet will, and has run away with itself. As the morning muster grows less and less and the call for work becomes more pressing, one has an idea that things have but to go on long enough and we will muster "the last man." Then there is the mighty contingent of the incapacitated which grows stronger daily and parades at the bungalow, shivering and barking in quite a harrowing way. What gallons of castor oil and handfuls of quinine have been swallowed, and even with it all our working force remains at a pitifully low ebb. Our best efforts seem to but drive the influenza devil out of one man, that it may find a home in another.

On the head of it all there comes this Sinhalese holiday, and your Sinhalese labourers somehow disappear: gone to sing carols, or erect pandals or decorations in honour of their lord Buddha, anything but stick to their work. If you chance to fall in with any of them just clearing out, the festive expression on their face before they saw you, changes into funereal sadness once they get their eye on you. If they are not dying themselves some of their relations are, and it is on an errand of mercy they are bound. It is at a time like this, when "the harvest is plentiful and the labourers are few," that the Sinhalese contingent is felt to be so unreliable. You may get Tamil coolies to work on a Pongal or Tivali, although perhaps not very willingly; but when a Sinhalese holiday comes round, it matters nothing how much you may be handicapped or behind with your work, the Sinhalese leave you to fight it out as best you can. If our old sources of supply had been untampered with, the tide of immigrant labourers would have been at its flood now, and there would have been help at hand. But the stopping of the ferries has done far more harm than those who ordered the measure know of. The Kangani who intended to do his best has had his resources wasted, and his recruited gang diminished by the uncertainty and delay: while those who have not been "square," will seize on the stoppage of the ferries as an excuse for their own misdeeds, and the amount of coolies which will have been lost to Ceylon, according to the calculation of those gentry will simply be limited by the force of their imagination. I would almost guarantee to say that there will hardly be an estate in Ceylon that will not hear of the Government interference with our labour supply as the reason why more coolies have not been brought in.

The opinion of Planters as to the sixty days' clause, and the fight which our member made in Council is not by any means a unanimous or solid one. Those however who seem to know best about all the difficulties which the hon. Mr. Christie had to contend with, account his efforts as highly successful, and that he has done a smart thing. There are however, on the other hand, those who

think differently and the meeting at the end of the month should be a more animated one than there has been for some time.

The rush of leaf keeps going on, and the short-handedness on estates will certainly tell on the quality of the tea being made.

The spring cacao crop is ripening, although not very rashly. Still with the present good prices, all that comes is welcome.

The weather is cloudy and windy. We would willingly take more rain, and we will get it in due time.

PEPPERCORN.

NOTES ON POPULAR SCIENCE.

PAPIER MACHE NUTS—DIAMONDS—INK-PLANT.
By DR. J. E. TAYLOR, F.L.S., F.G.S., &C., EDITOR OF
"SCIENCE GOSSIP."

Many of the huts which are being sent from this country to the South African goldfields, and to other places where portability is important, are made of wire-woven waterproof sheets. The sheets are less than half the weight of 24-gauge corrugated iron, for which they are intended as a substitute. Being composed of stout papier-mache, with fine steel-wire foundations, they are good non-conductors both of heat and cold. The total weight of a settler's hut, 14 ft. by 10 ft., is thus brought down to a little more than half a ton.

The origin of the diamonds in South Africa has just been discussed before the French Academy of Sciences. It was argued that the South African diamonds were not formed *in situ*, but were erupted from great depths, together with the fragmentary materials in which they are embedded. The presence of the diamond in its natural state, and as carbonado, as well as transformed from graphite,* in various stages of meteorites, is now placed beyond doubt. Attention was called to the analogous conditions of association under which this crystal occurs in South Africa, and also in meteorites. M. Daubrèe is of opinion that the diamond is not (as is generally supposed) of vegetable origin, but is of inorganic nature, as is also the graphite found in the same rocks. This will be a new idea for many geologists.

The last new tip from South America is the discovery of a plant in the United States of Columbia called *Coriaria thymifolia*, whose juices supply a ready-made ink, which is at first of a reddish colour but afterwards turns black. On this account it has been called the "ink plant."—*Australasian*.

NEWS FROM BRAZIL.

COFFEE UNDER SHADE—TEA, COTTON AND CANE IN CEYLON—THE REVOLUTION IN BRAZIL—COFFEE AND CAPITAL.

Mr. Hugh Blacklaw has kindly placed the following letter from his brother, Mr. A. Scott Blacklaw, at our disposal:—

Rio de Janeiro, March 18th.

I notice there is an attempt to revive coffee cultivation under shade in Ceylon: I believe the idea a good one. In the province of Rio which suffered much from a coffee disease some years ago planting has for sometime been again continued under shade, and some seven years old coffee and down to three years which has come under my observation I have noticed have grown and produced well. The tree used is of a family I have seen some in Ceylon, the *Ingás* of which there are several species here: *Ingá hymenafolia* is the best for this purpose, but others are being tried, and which I shall note by and by.

I have never seen any of the *fig* species tried, and shall be pleased to hear that *figus glomerata* is a success with you in Ceylon. Now here is a field for young

* Ceylon with its deep beds of graphite should be of interest in connection with diamonds.—ED. T. A.

botanists, of whom we know some to practise their science. There is much to find out, if only the reasons why one species of tree is better than another.

Tea planting I know nothing about, and I fear I would make bad weather at it. I believe cotton would pay well in Matale and Haputale; and having planted and grown it, I could enlighten my old neighbours, but I did all with ploughs and mules. There are so many writing in the *Observer* on "cotton" that, what I had to say on it would be passed over as "stale." If, however, I have to "loaf" in Rio for some time I may write to our friends of the *Observer* on it. By the way I had all the *Tropical Agriculturists* nicely filed from the beginning, and I looked on them as valuable references on agricultural and botanical subjects, but while I was absent in the interior some six months ago, the white-ants got where they were and in August last I found them beautifully honeycombed. The valuable maps in connection with and filed along them, which had cost so much to compile, these creatures respected not.

I believe *cane* could be made to yield sugar and rum to pay in many parts of Ceylon, but none but Companies could attempt it, the new style of machinery is so costly. Then without 30 inch gauge railway lines to transport the cane, the factory could not be kept in steady work. This cane cultivation pays best by being done with the plough.

People in Europe have not a very clear idea of what our Republic is. As far as I have seen it has made no difference. Things have moved on as if nothing had happened. True, I have been far away from Rio, but I subscribe to a Rio paper which gives all the news. As a proof that the change was needed we find every one supporting the Republic. We have also to consider that the change was affected and the position is still held by the army and navy, and the police all over the country is substituted by them, so that any expression of opinion contrary would be immediately checked. The reasons were principally three:—1st, discontent amongst the officers of the two services owing to measures having been taken by the late Government, which the army thought they should not submit to. It began three years ago when some officers of high rank were censured for breach of discipline in defending themselves in the newspapers from attacks made on them by members in their places in Parliament. Writing to newspapers being forbidden in the army. Then for some time the officers complained that their duties were being gradually absorbed by the National Guard (similar to your Volunteers, but which I have never seen nor heard of being paraded, although there are a good many officers called by their Military title all over the country) and the Police. Small things which looked large to fighting men with weapons in their hands.

2nd.—Was the Emancipation Law of 13th May 1888 which by a stroke of the pen after a *show of debate* for five days in Parliament put an unconditional end to Slavery? The Government of the day were slow to recognise the need of the slaveholders for advances of money to relieve them from a state of affairs so suddenly and unexpectedly brought about and this at the beginning of the picking of the largest coffee crop hitherto produced, so the slaveholders, or the proslavery portion of them (for there were always abolitionists amongst them) turned against the monarchy which had brought this about and openly professed republican principles.

3rd.—During the changes mentioned above the Emperor was in Europe where he remained for sometime suffering from diabetes, and his daughter who was Regent, carried on the Government. The

Emancipation Law received the support of all educated people, and that question alone would not have deposed the Royal Family. But the Princess Regent has all her life been a fanatical adherent of the Church of Rome, and she is married to Conde de Eu—son of a deposed French Monarch, and although he fought well for Brazil in the Paraguayan war he was disliked for reasons which I have never found out. He was a Field Marshal, but unpopular in the service. He was said to be *near and mean*, to look after his own interests, and those of his friends, and said to influence his wife in the selection of Ministers and other high state officials. They were naturally blamed for the policy pursued by the Ministry after emancipation, for instead of seeking to relieve agriculture from the blow recently given to it, money was voted to repair old churches, restore lapsed livings in connection with the Church, create new Bishoprics and Bishops for them, and instal a cardinal representative of the Pope. The Emperor came back sounder in body, but said to be weak in intellect. The Emancipation Ministry got so unpopular it had to resign. A new one was formed from the party which had a *minority* in Parliament, so a new election had to be announced, and in a place which takes months for communication from remote parts to the capital, an election cannot be effected in less than six months from its announcement. During this interval the Ministry and the Emperor can rule by *decree* pretty much as they choose. The acts of the Ministry to relieve agriculture satisfied the planters, but dissatisfied the Army and Navy. The embers smouldering for some years before broke out into flame, and although the Ministry had by the election lists a large majority it had not time to use it, for one fine morning the Military made all of them prisoners, and Don Pedro 2nd and his family were told to quit and in a couple of days were shipped to Portugal. The Military were strong enough to keep down all opposition and the Navy joined them at same time, but no opposition was attempted.

Thus was effected the so-called *bloodless revolution* of Brazil. The Minister of War fired on the officer who came with the announcement to quit his post, the arm missed fire, the officer fired back and sent a ball into the Minister's leg, but the wound was not mortal. The extracted ball is now being exhibited as a curiosity.

On the day the Government and Monarchy were deposed, a Proclamation was issued signed by the Commander-in-Chief as *President*, and others who composed a Provisional Government, everything was to go on as before. All contracts made by former Governments were to be carried out in their integrity. All Provincial and Municipal Councils were to be substituted by others nominated by the Provisional Government. Finally they were only to hold power until a constitutional Assembly representing the whole nation should meet and decide what was to be done, and this was decided to meet in September, ten months after.

The Provisional Government have made by decree various important reforms, amongst them the separation of Church and State. The institution of civil marriage, and the naturalization of all foreigners resident in Brazil at the date of 15th November—date of the Republic. Those wishing to retain their nationality have to give notice within six months to the Municipal Council of the place they reside in, all those so naturalized have all rights equal to Brazilian born subjects, to hold any post except that of Chief Magistrate (President.) Brazil is "the United States of Brazil." Provinces are "States" (Estados), Presidents of Provinces are "Governors" &c., &c.

In financial measures the Government have not been successful. Exchange has gone down, and foreign Capital is slow to recognise good security under the new state of things. The European Governments will not recognise the Republic until it hears the voice of the nation in its constituent assembly. No doubt all will right itself soon—order has not been disturbed although in European and American papers we see accounts of riots &c., &c, these are *real canards*. As far as the material prosperity of Brazil is concerned I believe the change will do good. Formerly everything was smothered up with officialism. When anything had to be done with the Government letters had to be got from its political supporters, and not being able to get these business could not be done. This will continue to a certain extent until things get consolidated.

Agriculture is progressing, free labour is working the plantations. The Government which was deposed, borrowed money and advanced to Banks at 3 per cent. The Banks charging 6 per cent, and taking the risk of loss on hypotheses. Many cases happened of the money passing to pay old hypothecated Bonds, but the most I believe went to the support of the planters. In the Province of S. Paulo large numbers of European families have settled on estates, and this Immigration is still continued. Other Provinces or States as they are now called are following the example of S. Paulo—Government sends the Immigrant family free to the nearest Railway station.

Coffee planting is being extended on all sides in new land: much faster than old Districts die out new ones are formed. The distance from the sea-port is considered nothing. Railway carriage makes up for distance. Railways are being made everywhere. There is at present a momentary check on these enterprizes owing to want of confidence in Europe, but on the Republic being officially recognized by all the European nations capital will flow its usual course.

Foreign capital employed in Brazil is not exclusively British. There is French as well, and a fair amount of Belgian. Brazil is rich in natural resources and with only a very few exceptions her Railway lines pay well.

There is talk of a land tax in lieu of the export duty. This will bring cheap land into the market a bad outlook for holders who will neither cultivate nor sell. There are thousands and thousands of acres held by large owners who will not cultivate the land nor will they sell it. Coffee land near a railway sells now from £10 to £20 an acre, and although there are large tracts in private hands, land can scarcely be had to buy. The proposed new law is being much discussed in the papers, and its advocates seem to have a strong side, that is putting it against *export duty*. In Ceylon you have no *export duty* and no need of a land tax and your endeavour should be to resist the latter as much as you can. Here it is different, the planter pays somehow or other on his coffee in Municipal, Provincial, and general Government taxes from 10 per cent to 12 per cent before the Agent for the European or American buyer can put it aboard ship.

COFFEE IN BRAZIL.—Sr. Luiz de Castilho, the Rio de Janeiro state agricultural expert, estimates that according to the present planting methods 4,000 coffee trees produce 80 arrobas of clean coffee, which at 5\$ gives 400\$. To raise this coffee one man's work for 300 days is requisite, which at 1\$500 per day amounts to 450\$; result a loss of 50\$ to the planter.—*Rio News*.

ABOUT THE HILL COUNTRY, CEYLON.
FLOWERS, FRUIT AND VEGETATION IN THE HILLS AND
IN THE LOWCOUNTRY.

Colombo, May 12th.

"From the Hills" is still an appropriate title for notes which have been brought down to be extended. Before returning to the Haputale railway summit and its wonderful series of tunnels, however, I must just glance at the effects of summer geniality at an altitude not far short of 6,000 feet and again at sea level. Before I left "the hills" on the 8th the outburst of bloom under the influence of nearly a fortnight of warmth and sunniness after the heavy rains of April, was calculated to convey an idea of what "the Indian summer" of North America must be. In the garden attached to Upper Abbotsford bungalow, the elevation of which is 5,740 feet above mean sea level, the show of blossom was such that I obtained from Mr. A. M. Ferguson junior, the following floral list. It does not include a considerable number of plants which are likely to blossom further on, but as the heading shews, only those actually in bloom, at the end of the first week in May—the violets, jasmines, honeysuckles and heliotropes, (the latter making wonderful growth,) being redolent of grateful perfume:

List of flowers at present in bloom in Abbotsford Gardens.—1 Arum (*Calla Ethiopica*); 2 Hot poker (*Tritoma ovaria*); 3 Bougainvillea; 4 Mauranoya barelayana; 5 Iris; 6 Verbena; 7 Sweet William; 8 Pink; 9 Poinsettia; 10 Rose; 11 Ohrysanthemum; 12 Jasmine; 13 Honeysuckle; 14 Thunbergia; 15 Loptospermum; 16 Lily; 17 Gladiolus; 18 Montbretia; 19 Bignonia; 20 Begonia; 21 Violet; 22 Ixia; 23 Fuchsia; 24 Duranta; 25 Plumbago; 26 Zinnia; 27 Brunfelsia; 28 Viscaria; 29 Phlox; 30 Stock; 31 Spirea; 32 Heliotrope; 33 Tecoma; 34 Dahlia; 35 Habrothamnus; 36 Whin; 37 Stone-crop; 38 Abutilon; 39 Francisca; 40 Ohamomile; 41 Crocus; 42 Jonquil; 43 Ipeacuanha; 44 Cornflowers; 45 Gaillardia; 46 Corcepsis; 47 Cactus; 48 Orchid; 49 Strawberry; 50 Shoe flower; 52 Indian shot; 53 Geranium; 54 Salvia; 55 Passion-flower; 56 Hydrangia; 57 ? Lilac; 58 Daisy; 59 Vinca; 60 Solanum; 61 Libonia; 62 Magnolia; 63 Gardenia; 64 Nicotiana; 65 Myrtle; 66 Petunia; 67 Stockrose; 68 4 o'clock plant; 69 Oleander; 70 Browallia; 71, 72, 73, 74, 75, and 76 names not known; (of many of the above there are from 6 to 12 varieties: lilies, for instance.)

Planted round the borders of the lake which supplies water-power for the tea-making machinery, the contrast between the large, purely white blossoms of the first named plant, ("Lily of the Nile") and the brilliant scarlet shading into orange, of the long spikes of the second, is very striking, and when both are reflected in the still water, the effect is very beautiful, colour as well as shape being reproduced in the inverted forms.—The growth of the heliotrope is such as to encourage the belief that this plant in our higher mountain regions, will yet vie with specimens we saw at Otacamund and Coonor, where a height of 12 feet and over is frequently attained by this plant. It is not merely grown in Gardens at the South India Hill Stations but actually utilized for hedges. All the way down, to Kandy and Colombo, the railway station gardens were glowing with rich and beautiful colours, and when I took my first drive along Turret Road, Colombo, and past the Banyan tree along the Lake sides, southern and northern sections, I no longer wondered that Mr. Henry Varley should have exclaimed, after I had given him a similar drive, in the corresponding season,—"I could not have imagined so much beauty in God's creation!" Residents in Colombo are fami-

* An opinion fully corroborated today by Mr. and Mrs. Axel Gustafson: the latter an American literary lady saying that Colombo was perhaps the only place that exceeded her expectations in every way.—*Ed. T. A.*

liar with the grand "Madagascar tree" *Poinciana regia*, with its emerald green, fern-like foliage, contrasted with its gorgeous masses of scarlet or orange flowers, relieved by spots or tips of white in some of the petals; but my sensations on seeing the wealth of blossom which had expanded and accumulated in the course of my two months' absence, enable me to appreciate the astonishment and the rapture of stranger visitors in this month of May and onwards to August to our beautiful city of widespread suburban parks and many miles (not far short of 100,) of splendid driving roads. Along those roads at present, in contrast to the peculiar, but elegant foliage, much of it pendent, of the casuarinas, and in contrast also with each other, are the *poincianas*, intense scarlet and deep orange, with *albizzias* and *cassias*, of golden or pale yellow, while the blossoms of one species of cassia, shade away from the most delicate pink (almost white) to the richest rose. The *poincianas* are now growing practically everywhere, and so are the foreign trees with similar foliage, but shewing rich yellow blossoms, because the natives have not discovered that the bark of those trees contain a curative principle, the existence of which in the bark of our own beautiful *cassia fistula*, (described as combining the foliage of the ash and the blossoms of the laburnum) has so sadly hindered its prevalence and led even to the destruction, by gradual decoration of numerous fine trees. But there is a grand specimen, now one mass of golden blossom in Mr. Jeronis Pieries' garden in Turret Road. Still more exquisitely beautiful, is the mass of pink and rose blossoms on the pink cassia in the garden of one of the houses near the Banian tree. The contrast here of the scarlet *poinciana*, the pink cassia, and the purple-red *bougainvillea*, with the grand scalloped leaves of the breadfruit tree, is something worth a journey to see. To view the *poincianas* in perfection, "Muirburn" garden, which is a perfect blaze of red and orange, contrasted with all shades of green, should be inspected. Then there are the brilliant trees at the house on the end of the southern division of the lake (near the Malay Cemetery) and the rows along the side of the northern section of the lake, near the Kew Police Barracks, where also the magnificent growth of the rain trees, (*Inga saman*) and their elegant pink blossoms are worthy of admiration. Colombo is now more than ever what the Russian Prince Soltykoff called it, half a century ago, "one vast botanical garden." It is already one of the most beautiful places in the world, with a wonderful variety of drives over good roads the red colour of which in contrast to the prevalent greenery, strangers greatly admire. But our city is capable, under the well-directed efforts of the Municipality of being rendered still more attractive, by the multiplication, as means permit, of such combinations of verdant turf, walks, fountains and flowering shrubs as is presented in the Gordon gardens, which have converted what I remember as one of the ugliest spots in the Fort into a perfect "thing of beauty." The improvement in the shape of the boulevard which runs southward from the new landing jetty and the Grand Oriental Hotel, promises to be still greater and more marked.—This year is not only abnormally a year of flowers, but also specially favourable for the production of fruits. There are the usual cart loads of pineapples in the bazaars, while mangoes and jak fruits are plentiful and cheap

* I suppose oranges are equally plentiful, and having been engaged in reading and making notes on Dr. Bonavia's great work on the citrus family, I am interested and amused by an advertisement from the enterprising dubash gentleman, Mr. Henderson, who is evidently about to establish an orangery on an extensive

beyond precedent. The main fruit season in Colombo is in the summer months of May, June and July, but the months in which vegetables can be most successfully grown, (mainly by irrigation,) are the dry winter months of January, February and March. A more complete contrast can scarcely be imagined than the wind-vexed, lichened, mossed, bearded and contorted natural forest on the dividing mountain range between west and east which the railway to Haputale is to cross, and the luxuriant palms, bamboos and flowering trees indigenous and imported, which are grown at Colombo.—But what was meant to be prefatory matter of a few lines, has grown, under the charm of the subject, to such length, that I feel it better to postpone a notice of my visit to the tunnel region of subterranean darkness and damp until next issue.

CACAO IN THE WEST INDIES.

The Lesser Antilles: a Guide for Settlers in the British West Indies. By Owen T. Bulkeley. (Sampson Low & Co.)—Emigration to the West Indies is an idea that has a certain novelty about it. We commonly look upon them as "played out." Mr. Bulkeley is not of that opinion. He sees in them a promising field both for labour and for capital. Here is a balance-sheet. An emigrant is supposed to go with a capital of £100:—

Ten acres of virgin land, at £1 per acre	... £10
Clearing and planting same, at £2 per acre	... 20
Building cottage	... 40
Implements and six months' living	... 30
The settler will plant cacao-trees, and will support	

scale in the congenial soil and climate of Cotta. I wish him the success he deserves. It would appear that no member of the citrus family is indigenous to Ceylon, and yet oranges, lemons and limes flourish in our soil and climate, the oranges improving in quality with altitude, up to close on 6,000 feet. In Australia and especially in Java, I have seen orange groves blighted to death, but I have never seen such a sight in Ceylon. It is a great pity however that our low grown oranges are pulled when green. The excuse offered is that if allowed to yellow on the trees, maggots would infest the fruit. But the real reason why, not only oranges but all other fruits are plucked in Ceylon, in an unripe state, is the thievish propensities of the people. If allowed to ripen on the trees, our ordinary orange would have flavour as well as juiciness to recommend it and Dr. Bonavia found that even green oranges from the bazaar, when kept for over a month until of a golden hue, were delicious. But our green orange is not the sweet lime of India, which seems never to have been introduced here. If therefore, Mr. Henderson obtains sweet limes in Ceylon, we believe Dr. Trimen will share our consequent surprise. "Mandarin" plants are of course, the so-called "Mandarin" oranges, the loose skinned orange of India and Ceylon, which Dr. Bonavia states is not the true Mandarin. That he found in Peradeniya Gardens, amongst plants which came from Egypt in 1842 and he strongly recommends planters to cultivate it. Meantime, good, well ripened, specimens of the loose [and brittle] skinned oranges of the Colombo Bazaars, (popularly known as "Mandarins") are very superior in flavour to the tight skinned green Oranges. In ordering "pumbloe" (pumelo) plants, Mr. Henderson ought to carefully choose the variety. The fruit varies from specimens with deliciously juicy, pink pulp, to dry and even dangerous productions. Once, after partaking of the fruit of a "wild" pumelo tree on the Yatewatte Pass, we were put into a state of alarm for hours, by sensations of heat and constriction in the throat. In India really good pumelos are confined to limited localities. We have fine varieties at Colombo and only these should be grown. This note is a mere feather floated in advance of a notice as elaborate as its merits deserve, of Dr. Bonavia's Monograph which we hope shortly to give in these columns.

himself by growing and selling vegetables till these come into bearing. On ten acres there would be about 2,500 of these. These would yield about £30 a year. The returns on a larger capital show very well. Of course the small capitalist would "work out," and a white man can do much outdoor work. Cacao is not the only industry. There are many other things grown. Altogether, the picture drawn by Mr. Bulkeley is very rosy, *Spectator*.

A REACTION IN QUININE IN AMERICA.

For some weeks past the quinine market has been in a depressed condition and it has seemed to be only a question of time when the price would once more settle down to the twenty-five cent basis. The heavy receipts at this port from the beginning of the year to date, amounting to an aggregate of over a million ounces, have had anything but a re-assuring effect upon speculative operators. If any disposition was shown to buy in a large way, say in lots of ten thousand ounces and upward, the intending buyer's limit was invariably half a cent or a cent below the price the lowest seller cared to accept, and as in the majority of cases the lowest quotations were made by those who were the most anxious to buy there was little chance for business.

In some quarters it is confidently believed that the market will soon go to thirty cents. This confidence is born of the belief that a reaction has set in the bark market, the small offerings at the last London auction and the withdrawal of a part of the stocks from the Amsterdam sale being interpreted to mean that the bark men have imbibed more exalted ideas of the future of that commodity from the strong showing made by the statistics, and are determined to get better prices. It is probable also, that the recent bears finding the market going against them will reverse their tactics in the hope of urging the price up to or beyond thirty-two and a half cents and we may therefore look for some strong bullish statements concerning the position of quinine during the next week or two. The bulk of the surplus stock which existed in London before the epidemic seems to have been transferred to this market, and if the position of bark remains as strong as at present the upward movement in the price of quinine in London will no doubt continue. In that event and provided the stock here is as well controlled as it is said to be, it will be comparatively easy for operators in this market to establish a higher range of values.—*Oil, Paint and Drug Reporter*, for April.

HOW TO GET RICH: RUBBER IN AFRICA.

Taking down a map of equatorial Africa and spreading it across his knees, the gentleman from Africa laid his forefinger on a certain spot and remarked:—

"If I were a young man with £2,500 or £25,000, I'd go there and make millions."

The spot he touched was the town of Upoto, on the River Congo, near the northern boundary of the Congo Free State, distant about 700 miles from the Guinea Coast.

"What would you do there?" inquired the reporter.

"Trade," was the brief answer.

"Ivory, skins, precious stones —"

"Rubber. You can buy rubber there today at a penny a pound. A young man might go there and pay fivepence a pound for it and make a fortune."

"Would you advise a young man to go there with more than £25,000, or less than £2,500?"

"Well, it would depend on the young man. The climate is excellent after you get back a hundred miles or so from the coast. There is no fever on the uplands."

"How is he to get his rubber to market?"

"At present most of it is carried on the backs of natives, and the lack of transportation facilities accounts for its cheapness in the interior. But you know the Congo is navigable for many miles—from Kinchassa, in fact, to Stanley Falls—and by-and-by we shall have a railroad down there which will make

travel easy all the way to the coast. I have recently put £12,500 in the road, and may put a little more after a while. I received a note from King Leopold asking me to call on him when I arrived at Brussels. I did so, and we talked over the situation in Africa. Leopold didn't know quite as much about railroad building as I did, so I gave him a few points. I am going into the railroad business in Africa simply because I want to break up the slave trade. I have been opposed to slavery all my life, and gave a good deal towards abolishing it. Down there in the heart of Africa is the beginning and the end of slave trade, and the time is not far off when we will wipe it from the face of the earth. I have also invested £12,500 in the proposed Berber-Suakim Railway, and £12,500 more in the British East African Railway. Thus I have £37,500 in the three roads. I don't look for any profits, but if any should come they will be reinvested in Africa."

The price of rubber in Para, Brazil, ranges up to 4s. a pound. If a young man could only get hold of £2,500, if he could only buy rubber in the Congo Free State at a penny a pound, if he could only get it down to the coast for a few pence more a pound, if he could only get it to Havre or New York for still a few pence more a pound—if he could do all this he would make a tremendous profit. Then if he could live within his income he would certainly grow rich. The principal thing with most young men is the £2,500, or rather the want of it. There are plenty of lusty young white slaves behind the counters who would like to be emancipated. And lots of them would go to Africa on much less capital than £2,500. In the present state of the market so princely a sum as that would purchase a gross of Congo Free Statesmen.—*The Star*.

CHINA TEA TRADE IN 1889.

How the demand for China tea in Great Britain is falling off is an old story, but those who ought in China to be most concerned at this have paid less attention to it than it deserves, because they have comforted themselves with the notion that Russia, the United States and Australia are still faithful to their old love, and have not been seduced by the younger charms of India and Ceylon, and that their continued adhesion compensates for the fickleness of the British tea-drinker. Even as late of last year, however, Great Britain took one-third of the whole export to foreign countries, so that China cannot yet afford to treat lightly the prospective loss of that market. The total export of tea of all kinds, black, green, leaf, dust, brick, and tablet, last year was, in round numbers, 1,800,000 piculs, which was brought up to nearly 1,900,000 piculs by the addition of the quantity sent overland from Hankow to Siberia and Mongolia, and by junk to Hongkong and Macao. In 1888 the total export was 2,170,000 piculs, and in 1886 the largest on record, 2,200,000 piculs. For the present purposes, however, we omit the Hankow overland and the junk export, and the 1,800,000 piculs remaining were divided as follows among the principal kinds:—

Black tea	1,300,000 piculs.
Green	"	...	200,000 "
Brick	"	...	300,000 "

while the quantities taken by the principal consuming countries were as under:—

Great Britain	600,000 piculs.
Russia	500,000 "
United States	300,000 "
Australia	150,000 "
Hongkong, and other British dependencies	190,000 "
Leaving for the rest of the world only	60,000 "

1,500,000 piculs:

The export to Russia, it will be understood, includes nearly the whole of the brick tea; so that of the total quantity of leaf tea bought from China, Great Britain

still took in 1889 three times as much as Russia, twice as much as the United States, and four times as much as Australasia. She is thus a customer whose wants and recommendations China cannot afford to neglect, unless she is prepared to bear a farther serious curtailment of her trade.—*N. Herald.*

THE REDUCED TEA DUTY AND
WHAT IS EXPECTED TO
RESULT FROM IT.

This mail brings us a greater variety of opinions than ever in reference to the effect of Mr. Goschen's reduction of the tea duty by one-third. Of course it is no use looking to the political journals for a useful opinion, their judgment being entirely coloured by their desire to aid or thwart the Ministry and the Chancellor of the Exchequer even on so small a matter as one of the heads of the Budget. But it is when we turn to the trade circulars of the men of long experience in the tea trade that we are inclined to listen with deference whether their opinions be favourable or unfavourable to the anticipations of Ceylon producers. But first let us reproduce some of the extreme views:—"No human creature except a few tea dealers will be benefited by flinging away a million-and-a-half in a partial reduction of the tea duty" is one such absurd statement; and again we are told the reduction will "only put money in the pockets of the producers or the middlemen." The former result is not likely to be objected to by Ceylon tea planters. But here is what a great organ of China teas has to say. We refer to the *London and China Express* :—

"In the vicinity of Mincing-lane the effect of the proposal has not been very great, but it has given a small spurt to the lowest class of teas in which Indian, Ceylon and China have all participated, more particularly, perhaps, the China article and the effect may be to get more of this class into consumption. The dealers apparently have not made up their minds about it at present, and each appears to be waiting to see what his *confrères* are going to do. We cannot say at all events that there is anything like enthusiasm in any part of the market over the coming decrease. The most said on the subject is about Mr. Goschen's attack on the middleman rather than on the actual reduction of duty. The very large profits that he mentioned are things rather of the past than of the present, and he is scarcely less happy when attacking the village grocer. Tea used to be one of the articles on which this class depended to make up for the exceedingly low rate at which sugar and other commodities were sold, but of late years competition has grown very keen, and prices have been continually cut."

Far more to the point and more worthy of attention is the outspoken businesslike declaration of Messrs. Rucker & Bencraft under date April 24th :—

"TEA.—Ceylon.—The one absorbing topic has been the twopenny reduction in the duty, and its possible or probable effect on the market. In our opinion the market has not yet been affected at all by the reduction. We pointed out on 20th March that there was certain to be a big business done when the duty question was settled, and we believe the same firmness we have seen at the last two Ceylon sales would have been shown had the Chancellor of the Exchequer determined to let the duty alone. Ultimately we have not the least doubt that the consumption of Tea will receive a distinct stimulus. This is, however, much wanted. In fact without a very marked increase in the consumption in the next two years, the outlook for Indian and Ceylon prices would indeed be a poor

one. Supposing under favorable circumstances people spend one-fourth of the remitted duty in Tea, we shall require for the next 12 months about 230,000,000 lb.

This would be practically divided as follows :—

Indian Tea...	108,000,000
Ceylon Tea	42,000,000
Sundries (no increase)	24,000,000
China Congou	56,000,000
			230,000,000

We think most reasonable people will agree in the view that "ultimately we have not the least doubt that the consumption of tea will receive a "distinct stimulus"; but none the less do we concur in the opinion that the larger available supplies will require an increased consumption. In their estimate for the next twelvemonths, Messrs. Rucker & Bencraft put Ceylon tea at a moderate figure, and their estimate for China Congou is so low that to support it, no more exports of this kind from China to the United Kingdom, than 40 millions will be required in 1890 against 72 millions in 1889. A falling-off of 40 per cent for China Congous would indeed mean a collapse. On the other hand there are Tea firms who are very strong on the point that the new duty must, of necessity, stimulate the demand for good teas especially Indians and Ceylons. Of such are Messrs. F. S. Long & Co. of Rood Lane who write under date 25th April :—

"On the first announcement of the proposed reduction of the tea duty the market remained quiet, but common China Tea in the Clearing House advanced three points. This advance was *entirely lost* after four days when it was found that the chief enquiry from the country was for Indian and Ceylon Teas. What the effect will be when the duty comes into operation (and it is now thought that it will be postponed to the middle of May, instead of the 1st. In our opinion this will be a terrible mistake, and do a serious injury to our market) it is difficult to say; but so far, we are entirely supported in the opinion we have always expressed, viz., that a reduction in the Tea duty would stimulate the demand for good Teas, especially Indians and Ceylons. We think the public will continue to buy the better grades at the reduction, which the keen competition among the retailers will guarantee, rather than the poorer ls. Tea which experience tells them is not economy. That the ls. Tea will be pushed in some districts is of course true; *but this will not interest Ceylon.*"

On the whole therefore, we think that Ceylon planters may look hopefully forward to the consequences of Mr. Goschen's reduction and may fairly anticipate as one result, a steadily increasing demand for their produce.

THE COFFEE PLANT:

COFFEE IN NEW HEBRIDES.

(*London Standard*, April 14th.)

Coffee has long been a favourite subject for experiments in tropical agriculture, and it would appear from an announcement just made that its successful growth in the New Hebrides is now an accomplished fact. The beans sent by the authorities of Kew Gardens to the Colonial Institute are; it is true, rather small, but from their general appearance and the character of the soil great expectations are formed by experts regarding the latest of the many localities into which the famous Arabian plant has been introduced. Hurricanes aside—and these tropical storms are serious factors in the planter's calculations—there can be no reason for doubting the soundness of the estimate. Bananas, sugar, arrowroot, oranges, and other products of the sun-lands have already proved quite suitable for the climate; and as tropical islands, especially

if a little damp, are considered the best spots for coffee growing, the New Hebrides need not be considered an exception to the rule. We fear, however, that if this oft-coveted group becomes attractive to planters, the question of its independence will once more come to the front. The species imported into the islands is, we presume, the Liberian coffee. Indeed, to experiment with any other would be to risk discouragement, since, apart from its merits as a crop, the West African *Coffea* has, as yet, alone resisted the disease which has ruined so many plantations of the Arabian species.* Ceylon, not many years ago, attracted a large amount of British capital, and for a time it appeared as if this rich Indian island was to be the greatest of all the coffee-growing regions of the world. But before long the woes of the planter began. The Goulunda rat gnawed the trees, and the coffee bug played havoc with the beans. Then came the worst of all its pests, in the shape of the leaf fungi, which all but completed the destruction of what the others had spared. The result is that tea, instead of coffee, is now the staple of the Sinhalese planters, and happily, for the present, the Chinese herb bids fair to more than compensate for the loss sustained by the Arabian tree. The Liberian coffee-plant is, curiously enough, free from the parasitic attacks, possibly because being more recently reclaimed from a state of nature, its constitution is less enfeebled than the old variety, which has been cultivated for at least a thousand years, though in Arabia it does not date further back than the early part of the Fifteenth Century. The Liberian plant, has, in addition, the advantage of being very prolific in highly aromatic beans, and as it loves low lands, it can be grown at altitudes unsuitable for the Arabian coffee, the native country of which is the uplands of Abyssinia.

But something more than climate is necessary to a profitable coffee plantation. It requires a well-watered mountain slope not much over twenty-five degrees from the Equator, and between one thousand and four thousand feet above the sea, where the mean temperature is not less than fifty-five degrees. Then, the soil must be friable and well drained, and enriched by the fresh loam which is being constantly washed down the hill-slope by the Tropical rains. In Quito and Peru, no doubt, there are plantations at a height of six thousand feet on the Andes. But even at this elevation in such a climate frost is unknown. Moisture is especially necessary, and if the rainfall is deficient, the ground must, at intervals, be carefully irrigated. For at least three years after the seedlings are set out no return can be expected, while the labour of the cultivator in weeding, cleaning, pruning, draining, and "handling" the plants generally has to be unremitting, if his hopes are not to be doomed to disappointment. In the third year the little shrubs begin to yield a remunerative crop: Yet, even at the best of times, the ordinary Arabian variety cannot be reckoned upon to bear more than from one and a half to two pounds † of berries in a season, though much depends upon climate, soil, and situation. The Liberian species is said to sometimes bear as much as sixteen pounds ‡ of marketable beans during the eight months it continues to flower. Three gatherings are usually made every year; since the berries, owing to the circumstances mentioned, may at any period be of unequal ripeness. These operations naturally require great care, judgment, and experience, for the value of coffee depends entirely upon its flavour, and such a seeming trifle as not cutting off the irrigating streams at the proper time will injure the aroma

* This shows how much the writer knows: he would be surprised to learn that in Ceylon, the Liberian trees developed bigger crops of the leaf fungus than could be seen on the bushes of the Arabian species! We are somewhat puzzled to understand the apparent immunity of Liberian coffee from the fungus in the Straits and North Borneo. Accounts of flourishing plantations reach us, with no mention of the fungus. Besides, the "rather small" beans sent to the Colonial Institute must have been the produce of the so-called Arabian plant.—Ed. T. A.

† Absurdly high: $\frac{1}{2}$ lb. is very good.—Ed. T. A.

‡ Too high by far.—Ed. T. A.

of the berries, while a deficiency in the water supply or the presence of weeds between the rows is equally apt to reduce their dimensions. The latter point is vital, for the shape, size, and colour of the beans are among the principal elements which determine the value of a crop, and all these points are affected by very trivial circumstances. Then, the shape seems related to the particular part of the plant upon which the berry grows, the size and succulence on the nature of the locality, while the colour has, according to the investigations of Mr. Hiern, reference to the degree of maturity which the fruit has attained at the time of gathering. The nicety with which the beans are sun-dried and passed between rollers, in order to remove the external pulp and the membrane enclosing them, has also an influence on the esteem in which they are held. Thus we have the matchless Mocha coffee from Arabia, easily distinguished by its small greenish-grey beans; Java and East India, with large yellow ones; Jamaica, with beans rather smaller and greener; Bourbon, distinguished by its pale yellow and almost whitish beans; and Surinam coffee in which the beans are larger than in any other kind. But in these and a score of other varieties there are various grades of quality—"fine," "middling," "ordinary," "low," and "triage," the last being broken seeds. The New Hebrides have, therefore, a good many preliminary obstacles to overcome before they can manage to find a recognised place among the coffee-growing countries of the world.

We are, indeed, doubtful whether the mere circumstance that the islands, or any one of them, may be able to harvest a saleable crop of the bean is anything more than an interesting scientific fact, unless the crop can be put on the market at a smaller expense than that of Brazil or Arabia, or is of a much finer quality. For there is plenty of coffee for sale and much more would be available did it pay to produce. Up to nearly the close of the seventeenth century Europe depended for its coffee upon Arabia alone. But in 1670, Mynheer van Wieser, the Burgomaster of Amsterdam, introduced it into Batavia, and since that period the original home of the plant forms a comparatively insignificant source of supply. Brazil and Central America grow enormous quantities. So do Venezuela, Guiana, Peru, and Bolivia, in the Southern half of the New World. Java is one great coffee plantation, and Ceylon, in spite of her troubles still harvests an appreciable quantity. In Southern India the cultivation of coffee is an important and ever-growing branch of rural industry; in Sumatra, Réunion, Mauritius, and along the West Coast of Africa it affords employment—and occasionally wealth—to a great many people; while, if Mr. Stanley's somewhat sanguine dreams take a substantial shape, Central Africa and the Upper Congo are soon to rank among the lands which are to compete with the great coffee growing regions. It is, therefore, clear that quality and low prices, which depend on cheap labour, cheap land, suitability of soil and climate, freedom from animal and vegetable plagues, and easy access to markets, are of paramount importance. All these may be found in the New Hebrides, though for the present it would be safer to moderate our expectations, until a few crops have been disposed of profitably. The mere fact of any locality yielding a particular product is only one point gained. Coffee often ripens in the conservatories at Kew, though we fancy this incident would scarcely be considered an argument for ranking *Coffea Arabica* among the future saviours of British agriculture. What the practical botanist ought now to consider is, how best he can produce a hardy variety of the plant, proof against disease, and capable of yielding a large supply of berries. With the results of hybridisation before us, this, one might venture to think, ought to be within the power of Science. There are some fifty or sixty species known in a wild condition, if the American forms are to be referred to the same genus as the Asiatic and African ones. Surely, when pedigree wheats have been selected from "sports" in ordinary crops, and other agricultural plants made to yield fourfold what they do in a wild condition, a little care in "breeding" ought to produce a much improved coffee plant.

LONDON AND COLOMBO TEA SALES.

An interesting discussion has been carried on in our columns and in that of a contemporary as to the respective advantages to planters of selling their tea in the Colombo and London markets. One proprietor has given very practical attention to the subject by dividing his consignments of teas into two equal parts, one of which has been sent to London and one to Colombo and this has gone on for over twelve months with the result of the Colombo sales showing a small fraction better return than that from the teas sold in London. There are some planters however, who strenuously hold that Mincing Lane is the better market for them and who show exceptionally low charges on their teas. A correspondent "C. T. G." of our contemporary who maintained at first that the charges on his teas equalled only 1 l-16th d. per lb, is among these; but his statement has been challenged and contradicted by two others as follows:—

"C.T.G." considers 2d. per lb. above the average charge on tea in London. Taking into consideration what this charge represents, namely, shipping charges, freight, London charges, draft (allowance of 1 lb. per package), and last but not least the risk of exchange and the market, his calculation of 1 l-16ths d. per lb. is palpably inaccurate. "Seeing is believing" as the saying goes, and it would be a benefit to his co-planters to expose the high rates estimated of 2d. per lb. by publishing the particulars by which he arrives at the exorbitant rate of 1 l-16th d. per lb.

If C. T. G. positively asserts that he can lay his tea down in London, so far as freight and London charges go, for 1 l-16th d. per lb., of course I cannot contradict him. But is not his case exceptional? I think that, in calculating 2d. as the equivalent of these charges, Colombo buyers are not far out. I add at foot the charges on a parcel of 206 packages shipped by me from Colombo recently to London, and it will be seen that the total charges come to £142 8s 5d. or a little over 1½d. per lb. This invoice is no exceptional one, as everyone doing this business will see for himself. As it may be of some interest, I add it below:—

Shipped 206 packages...	...	19,962 lb.			
Sold in London	...	19,462 lb.			
Loss in weight and draft	...	500 lb.			
			£	s.	d.
Freight	44	0	8
Warehouse and Rent	30	0	11
Interest	0	19	11
Sale expenses	1	0	7
Fire Insurance	1	10	3
Brokerage, 1 per cent	8	0	3
Commission, 2½ per cent	20	0	7
Shipping and export duty, ¾ cents	R 148 77				
Marine Insurance, ¾ per cent...	R 57 74				
Commission for drawing, 1 per cent	R 83 67				
			R 290 18		
Loss in weight 500 lb., @ 40 cents			R 200 00		
			R 490 18		
@ 1/6 =	36	15	3
			...	142	8 5

£142 8 5 + 19,462 = 1 75d or say 1½d per lb.

The above I am sure is a fair account of these charges which amount to quite 1½ per lb. and sometimes more. But does C. T. G. think that buyers are so blind to their own interests that they do not know that they may give another cent or so a lb. on a certain lot of tea and yet make money on it!

To this "C. T. G." replies and offers a correction and explanation as follows:—

I find I made a mistake in the charges of my last account sales; you will see from enclosed they come to 1½d per lb. and not 1 l-16th. I very much regret the error, but at the same time I enclose another account sale in which the charges work out fractionally over 1d. But as a rule you may take 1½d as a minimum. In my last I said, "London charges," which do not of course include shipping and export

duty (about balanced by brokerage in Colombo.) And I do not go in for such luxuries as 2½ per cent commission, not being able to see why the merchant should get two and a half times as much as the broker for a fifth of the work.

Of course "C. T. G." must be working under exceptional circumstances to be able to save commission &c. There is no doubt room for the planter in a time of brisk competition to profit by local sales; but the Colombo market must be uncertain from its limited character. Every day however is modifying this objection. The number of independent buyers of tea has lately increased and is bound to go on increasing; and the number of outside orders for our teas from the Australian and other British Colonies and America is steadily on the increase, and unless the local market is well supported with supplies by the planters, such orders must necessarily be discontinued and lost. It is from this point of view especially that we have been directing attention to the subject and urging the owners of fine teas even, to give a fair trial to the local market. In order indeed to encourage direct orders from other countries than England to Colombo,—a very important matter in the interest of producers,—it may be necessary to induce the Tea Fund Committee to move with a view to getting a certain percentage of most crops allotted for the Colombo sales.—Complaint has been raised about the dearth of freight from Ceylon to New Zealand the rate being as high as R52 (=£4) per ton or the equivalent of 5 cents per lb., and nearly three times the rate to London. We trust the day will come when more than one steamer can be chartered and loaded up with Ceylon teas for Australia and New Zealand at much lower rates than now prevail.—We give on page 474, the latest information in reference to the estimated tea crops in 1890 for India and Ceylon:—the former is put at 115 millions lb. and the latter we give at 45 millions though it is just possible that Ceylon may not be far short of Assam which is estimated to give 48,295,344 lb.

"ANOTHER NEW PRODUCT,"—

This time from a curious quarter—viz., the upas or upas tree, of evil fame—the very devil, indeed, of the vegetable kingdom—long supposed to destroy every living thing that came within its reach. Who does not remember his granny speak with bated breath of how condemned criminals were sent to report upon these trees till the ground was strewn with their bones, for "man, nor beast, nor bird, nor fish could live for twal miles around"? But modern research makes sad havoc of our cherished fables. Like its spiritual prototype, the upas has been found to be not so black as painted; on the contrary, a closer acquaintance revealed the fact that it belongs to a most respectable family—a very near relative of the cow tree (*Brosimum*), which yields milk as luscious and wholesome as any Alderney, and a first cousin, at least, to the famous bread-fruit tree (*Artocarpus*). In short, the upas has been malignd; it is not the cause of the malaria around it, but the cure, the seeds being found very beneficial in both fever and dysentery. Commercially, however, the tough bark is the most valuable product. In Ceylon this is made into strong ropes. In Western India the upas is known as "Sackin tree," the inner bark being extensively used as natural sacks for rice. And listen, O tailors on strike! This vegetable sweater—heedless of trade unions—works night and day in producing ready-made clothes! The felt-like bark removed entire, forms splendid seamless suits—the trunk furnishing bodies, the branches sleeves or legs, as the case may be. If really fine raiment is desired, the material is rolled and dyed, when it is fit for any "masher." Costumes of this natural cloth have at

tracted much attention at recent exhibitions. There seems also a likelihood of the fibre being found admirably adapted for paper making. Can men be said to be poor who live in a country where bread and ready-made clothes grow on trees, and where gallons of toddy gush out by simply tapping the flower spathes? — "Coloniensis" in *Aberdeen Free Press*.

SALE OF EKELLE CINNAMON ESTATE.

This property, which belonged to the estate of the late Mrs. H. A. Driberg, was purchased on 10th instant by the special mortgagee, Mr. S. Grenier, for R1,100. The mortgage debt being about R40,000. The estate as purchased by Mr. Grenier, is, in extent, about 123 acres, about 20 of which is all coconut. There is also a good sprinkling of coconuts amongst the cinnamon. Land in the Negombo district is just now very valuable, and although the price of cinnamon at present is very low, the price of cinnamon land ranges from R200 to R300 an acre. The soil at Ekelle is excellent for coconuts. Mr. J. F. Driberg will remain on the estate as superintendent.—*Com.*

CEYLON TEA PLANTATIONS COMPANY, LIMITED.

Directors:—David Reid, Esq., Thomanean, Kiarrosshire, Chairman, Henry Tod, Esq., 21, Mincing Lane, David Reid, Esq., 7, Mincing Lane. Managing Director:—H. K. Rutherford, Esq. Secretary:—Sir W. Johnston, Bart. Manager in Ceylon:—G. A. Talbot, Esq.

Report of the Directors to be submitted at the Third Annual General Meeting of Shareholders to be held at the Offices of the Company on Tuesday, 29th April, at 2.30 p. m.

The Directors have the pleasure to submit the General Balance Sheet and Profit and Loss Account for the year ending 31st December, 1889 duly audited.

The net amount at credit of Profit and Loss Account, including Balance brought forward at 31st December, 1888, and after providing for General Expenses, Director's Fees, Income Tax, &c.

	£23,651 18 10
An <i>interim</i> dividend of 6 per cent. was paid on 18th September, 1889.	£7,322 8 0
A second <i>interim</i> dividend of 4 per cent. was paid on 25th January, 1890	4,881 12 0
It is proposed to pay a final dividend of 5 per cent. (making 15 per cent. in all, free of Income Tax) which will absorb	6,102 0 0
To write off balance of Preliminary Expenses	265 0 0
To write off for depreciation on Office Furniture	67 2 3
To write off for depreciation on Buildings and Machinery	1,800 0 0
To place to a Reserve Fund	3,000 0 0
And to carry forward to next year a balance of	213 16 7
	£23,651 18 10

The Directors are glad to be able again to declare a total dividend of 15 per cent on the year's working, after writing off the sum of £1,800 for depreciation on Buildings and Machinery, and laying aside £3,000 as the nucleus of a Reserve Fund.

The gross average realized for the Company's Tea Crop of 1889, sold in London, was 11d as against 10½d per lb. for the previous year.

The Tea Crop from the Company's Estates was 937,407 lb. The Tea made from green leaf purchased by the Company was 799,779, lb., and the Tea manufactured for other Proprietors was 277,149 lb., making a total of 2,014,335 lb

The following is a Statement of Acreages of the Company's Estates as at 31st December, 1889:—

Estates.	District.	Elevation above Sea Level Feet.	Tea in Bearing, 1889.	Tea not in Bearing.	Approximate Acreage to be opened 1890.	Coffee Acres.	Jungle Waste, &c. Acres.	Total Acreage.*
Dunedin	Kelani Valley	500	382	30	8	—	110	525
Dewalaksana	Do.	500	336	133	—	—	125	594
Mudumana	Do.	800	—	505	50	—	640	1095
Sembawatte	Yaakdesa	1600	330	8	—	—	387	675
Mariawatte	Gampola	1600	424	255	19	—	294	923
Alton	Maskeleya	4300	366	44	10	—	30	450
Walla	Dimbula	4400	205	4	—	—	21	260
Tillyrie	Bogawantalawa	5000	520	—	—	—	236	756
Scrabs	Nuwara Eliya	6000	110	14	—	—	15	139
			2673	993	82	0	1638	5446

The results obtained from the working of the estates purchased last year, have, so far, the Directors are glad to say, fully borne out the anticipations formed of their value

On 25th March last, the Shareholders sanctioned the purchase of the estates of East Holyrood, Waverley, Tanga-kelly, Cymru, Cameron's-Land, Lochiel and Rosita, and the Directors have pleasure in stating that the Company has been placed in possession of these properties, and it is confidently believed they will prove very valuable acquisitions. In order to provide for the purchase and development of these and other possible additions, the Directors contemplate, with the approval of the Shareholders, increasing the capital of the Company to £300,000, one-third of which will be in the form of Preference Shares.

Statement of Acreages of Estates recently purchased:

Estates.	District.	Elevation above Sea Level Feet.	Tea in Bearing 1889.	Tea not in Bearing.	Approximate Acreage to be opened, 1890.	Coffee—Acres.	Jungle Waste &c. Acres.	Total Acreage.
East Holyrood	Dimbula	3,900	339	56	90	10	—	495
Lochiel (including Cameron's Land)	Do.	4,100	329	30	120	—	131	490
Rosita	Do.	4,100	30	—	—	—	160	31
Tangakelly (including Cymru)	Do.	4,700	363	—	100	—	399	862
Waverley	Do.	5,000	51	19	—	—	157	157
			1,142	105	310	67	690	2,314

The Directors have pleasure in stating that Mr. H. K. Rutherford, the Company's late Manager in Ceylon has taken up the office of Managing Director in London, and that Mr. G. A. Talbot has been appointed his successor. The Directors again desire to express their appreciation of the zeal and ability displayed by all the Officers of the Company in Ceylon and London.

BALANCE SHEET, 31st Dec. 1889.

USEFUL PLANTS IN GUATEMALA.

COFFEE—SUGAR—COCOA—PEPPER—CINNAMON—COCA—TOBACCO—RUBBER—BANANAS—FIBRES.

In a report on the trade, commerce, and industries of the Republic of Guatemala for 1888, the British Consul draws attention to the various vegetable products cultivated in the country. Coffee is described as the most important agricultural product, and from its excellent quality fetches a high price in the market. The area of land planted has possibly doubled in the last few years, and owing to failure in the last year's crop in Brazil, and the consequent rise in the value of the product, an usually large acreage of fresh land is now being planted, and greater care taken with the present estates, many old plantations being renewed and added to. It is expected that next year, or the year after, 1,000,000 quintals will be produced, bringing, exclusive of consumption, a wealth of £2,300,000 to £2,500,000 to the country. There is still a quantity of good land available for purchase. Sowing is generally done in June, and when about seven inches high the young plants are transplanted into nurseries, watered in the dry season, and protected from the sun until ready to be planted out. About 100,000 quintals of coffee are yearly consumed in the country.

Sugar stands next amongst the most important vegetable products. Cacao cultivated in Guatemala is of superior quality, and at one time it was an important article of export, but has of late years greatly fallen off, and at the present time only about 400,000lb. are pro-

duced, scarcely more than is required for interior consumption. The Government are encouraging farmers to turn their attention to this branch of culture, and some new plantations have been made. The seeds have been distributed in considerable quantities in various parts of the south, the sowing has shown good results, and it is expected that the cultivation of this valuable plant will be much increased. It takes about six years from the time the seed is sown before a crop is produced, but after that period each shrub will yield one pound three times a year, and last for 100 years. There is little cost in cultivating or gathering, no machinery is required, so that though there is some time to wait before new plantations give any return the ultimate profit is considerable. A slightly earlier result may be obtained by surrounding the plantation with lime or orange trees, well preparing the land, and shading the plants with suitable trees.

A quantity of coca seed (*Erythroxylon coca*) was last year imported from Peru for distribution among the people in a suitable zone for its growth, but the result was unsatisfactory, from the bad quality of the seed, and fresh means are being taken to extend the cultivation of this plant.

Pepper and cinnamon are grown in the department of Alta Verapaz. Good seed has been imported from Ceylon, and planting is extending in that fertile district, while satisfactory results has been obtained in the department of Escuintla, where a few plantations have been made.

Rice is a very large article of consumption in the Republic, and the Government have established at San Jose works for perfecting machinery to separate the husk.

Good tobacco is grown, but little attention is paid to the mode of preparing it. The production is being encouraged by the gratuitous circulation of the best seed procurable from Havana, the United States, and Sumatra, and many new plantations are being made.

In spite of endeavours made to protect the rubber or caoutchouc trees, the production of rubber continues to decrease, and only in Verapaz and Peten are trees found in any quantity, while the growers show no signs of replacing those that are worn out. Holes are made in the stems to extract the sap, and alum, saltwort, or some other juice used to coagulate it. It might be made a profitable industry if proper knowledge and appliances were brought to bear. A few new plantations are being made in one or two low-lying farms; about 3,000 quintals are annually exported. The plant yielding Guatemala rubber is *Castilloa elastica*.

Amongst other products grown are maize, beans, peas, and potatoes in sufficient quantity for home consumption; sarsaparilla and vanilla grow wild on the mountains all over the country. The price of sarsaparilla has fallen greatly; there was scarcely any exported last year, and in 1887 it only reached the value of £1,621. The quality of the vanilla is good, but though it figures as an export, it is not cultivated for that purpose.

Banana planting in the east is occupying much attention as a profitable industry, some 200,000 trees being now yearly planted for the supply of the United States market. About 120,000 bunches are at present exported annually. Peruvian bark has proved a failure, and the cost of introducing the tree has been practically lost. Ramie (*Boehmeria nivea*) was also introduced three years ago and more than 600,000 shoots were distributed, with a view to its general cultivation, but exportation of the fibre has not met with satisfactory results. Indigo works are subsiding in the country, though a few still exist in the east, and means are being taken to encourage them. Indigo was exported to the value only of £93 in 1888, though formerly a very large trade was done in it. The industry in cochineal has almost entirely disappeared; for thirty years it was the principal article of export, and now the little produced is used for native consumption, aniline dyes having ruined the trade.—*Journal of the Society of Arts.*

A SMALL consignment of Italian chestnuts have recently been safely imported into Cashmere.—*Times of India.*

THE TOBACCO PLANT.

After the cereals, there is perhaps no plant so extensively cultivated and utilised as the tobacco plant. It is grown and employed as a narcotic in almost every country of the world, and it has been calculated that one-fourth of the human family use it.

At the Colonial Exhibition in London the dried leaf and its preparations were shown by India and every one of our possessions, and the Paris Exhibition has supplemented this display by showing its extensive production in Europe, North and South America, Eastern Asia, the Pacific Islands, and the continent of Africa.

It is somewhat difficult to obtain trustworthy information regarding the world's trade in tobacco, because so much is used up locally in different countries. It is probable that the total area under tobacco is not far short of 6,000,000 acres. For the year 1886 certain official returns are available, which show that the United States, India, and Hungary are the largest producers.

The area under tobacco in acres was in—

United States	752,520
India	641,000
Hungary and Austria	149,468
Germany	49,312
France	37,156
Algeria	20,478
Italy	12,061
Holland	3,218

2,106,213

The consumption of tobacco in the United Kingdom is large and progressive, and the revenue derived from it last year was nearly £8,750,000. The average consumption is largest in Holland.—nearly 7 lb. per head; in the United States about 4½ lb.; in Hungary, Denmark, Belgium, and Germany from 3 to 3½ lb. In the Australian Colonies it is also high—3½ lb.; in France it is about 2 lb., and in the United Kingdom under 1½ lb.

The yearly production of tobacco in Cuba is about 300,000 bales, and 181,000,000 cigars are also exported. The Spaniards have hitherto monopolised the trade in cigars, alleging that parts of the soil of Cuba were alone suited to the production of Havana tobacco. This assertion is now disproved, for with good choice of seed, soil, and leaf, and skilled manufacture, Jamaica is said now to send into the market as excellent a cigar as was ever shipped from Havana, and at a far cheaper rate. In the Philippines 100,000 cwts. of tobacco are produced. The Dutch possessions in the Eastern Archipelago ship a large quantity of excellent tobacco, which is held in high repute in Europe. The imports of Sumatra tobacco in Holland now average 140,000 bales, and of Java tobacco 130,000 bales.

Although there are about fifty species of the genus *Nicotiana* known, only three or four are much cultivated for the leaf. The two principal commercial forms are by some botanists treated as varieties, and not as distinct species. These are *N. Tabacum*, the most extensively cultivated kind of plant, which may be at once recognised by its longish pink flowers and tapering oval-lanceolate sessile leaves; and *N. rustica*, which has short greenish flowers and stalked ovate, cordate leaves. The leaves are coarser and more crumpled than those of the preceding. This is popularly known as the Turkish form, but it is most probably a native of Mexico and California. *N. repanda* is not very extensively cultivated, but is said to yield some of the finest qualities of Cuban tobacco. *N. Persica* furnishes the Persian or Shiraz tobacco. *N. angustifolia*, a species found in Chili, yields a very strong tobacco.

The West Indian, Latakia, and American tobaccos are obtained from cultivated plants of *N. Tabacum*, while the Manila, Turkish, and Hungarian are reported to be derived from *N. nistica*. In India *N. rustica* is only cultivated to a very limited extent, and chiefly in Eastern Bengal and Cachar, and the leaf is never exported to Europe. *N. Tabacum* has become an abundant weed in many parts of India. The gross annual value of the tobacco harvest in Bengal may be roughly estimated at £2,000,000 sterling, but the quantity exported is small, averaging only £13,000 in value.

Of the species, *N. macrophylla* is considered to possess the qualities that distinguish a good tobacco in the highest degree. Some of the Havana tobaccos belong to this species. Madras, where the climate is admirably suited for the growth of tobacco, stands first with regard to the development of this industry in India. Dinnigul is the great tobacco district, and cheroots are manufactured at Trichinopoly. The islands in the delta of the Godavery also yield what is called Lunk tobacco, the climate being suitable, and the plants are raised in rather poor light soil, highly manured and well watered. No better evidence could be afforded of the universal use of this plant than the extensive display which was made of it in every section of the Paris Exhibition, and although most of the cases were under seal of the Customs, yet many of the kiosks were privileged to sell, such as the Dutch, Belgian, Spanish, Mexican, &c., although the sale and manufacture is a Government monopoly in France, and licenses are only granted to privileged people.—*Journal of the Society of Arts.*

FARMING AT CAWNPORE EXPERIMENTAL STATION.

In the Council report for 1888 we read:—It is not claimed that anything novel in regard to value as manure of gypsum has been evolved at the farm; but we seek by experiments to prove that its worth in India is as great as its reputation elsewhere and to rouse attention to the fact, that owing to recent railway development vast quantities of a valuable mineral manure at comparatively small cost are now open to farmers in this country, which until the last 2 or 3 years were partially inaccessible. For the rabi season the chief results obtained are summarised by the Assistant Director to have been—

- (1) that the application of saltpetre has a more direct effect on straw than on grain.
- (2) that the most economical manure for wheat is farmyard manure.
- (3) that when farmyard manure cannot be obtained at a sufficiently cheap rate, green soiling with hemp is the most economical way of enriching the land.
- (4) that good results can be got by using various waste substances now neglected of the people.
- (5) that a moderately deep ploughing of 5 inches gives better results than ploughing so deep as 9 inches.
- (6) that to feed cattle with cake and apply the dung to the land is more economical than to apply the cake direct.

The usual quantity of ensilage was made and proved perfectly good.

Trials with various machines were carried out, in particular of two new patent sugar mills. A centrifugal sugar refining machine, a centrifugal cream separator, a grain separator worked by power, three different water lifts, and three kinds of hand-threshers were amongst the new implements placed on their trial. It was mentioned last year that cultivators in the neighbourhood of the farm had begun at last to borrow our ploughs and water-lifts, and the same has occurred in the past year. Our progress in inducing cultivators to adopt what we can demonstrate to them to be sound improvements may be slow, but to those who expect in India rapid reform in such matters may be commended a study of Mr. Prothero's work—"The Pioneers and Progress of English farming." Writing of the close of the 18th century, he says, "traditional practices were traditional heir-looms which farmers guarded with zealous care, ocular proof of new systems failed to wean them from the routine of their ancestors." "By immemorial custom in Gloucestershire two men and a boy, with a team of six horses, were employed for ploughing. Mr. Coke sent a Norfolk ploughman into the country who, with a pair of horses and a Norfolk plough, did the same amount of work in the same time. But though the annual expenses were thus diminished by £120, it was 20 years before neighbours profited by the lesson." "In 1780 a Norfolk farmer settled in Devonshire

where he cultivated turnips on the newest methods. His crops were larger and finer than those of other farmers, yet at the close of the century none had followed his example. At the end of the 18th century Irish farmers still used sledges, still sowed their potatoes broadcast, still worked backwards before their teams striking them in the face, where they wished them to advance, still drew their ploughs and harrows by their horses' tails. An Act of Parliament was even at one time necessary in England "agaynst plowynge by the tail."

AGRICULTURAL AND INDUSTRIAL EXHIBITION, SUVA.

On Saturday last at noon the Governor arrived at the Exhibition; and the strains of the National Anthem played by the Good Templars' Band announced His Excellency's entrance into the building where the President and officers of the Association were in waiting to receive the Governor and Lady Thurston. The former welcomed His Excellency in terms which were too faintly uttered to reach any other ears than those to which they were immediately addressed, and as this journal has not been favored with a copy of the speech we are unable to record it.

The Governor's address in reply was as follows:—

Mr. President, it affords me pleasure to observe that notwithstanding the absence of encouragement and support which the Association you represent so worthily deserves, and in spite of many other difficulties and drawbacks, the year 1889 will not pass without a local Exhibition of those products upon which the prosperity of the Colony depends.

It is also a pleasure to learn from you that the general character of the exhibits offer a market value over those of last year. We can, however, hardly hope to make any very rapid advancement in our production, whether in volume or value, so long as a depression in trade continues to beset those older communities upon which we so largely rely for a market. But it is encouraging to note that there appears to be at least a small rift in the clouds that so long hung over those outside trading circles, and I must congratulate you upon the fact that we, though the subject not long since of dire forebodings, have as a community not lost heart, nor has the Colony, if I may use a sailor's phrase, lost steerage way.

I most fully share the regrets, Mr. Mune, upon which you have lightly touched with regard to the want of support the Association receives from those whose prosperity is involved in the interests, it is your object to promote; but I believe your Association will yet receive the full encouragement of which it is so worthy.

One of the anxieties constantly present in my mind is that Fiji may fall into that condition which is described in the expression "a one product Colony." Now if there is one factory more than another that should be potent in averting this unhappy fate, it is an Association, such as yours, which encourages diversity of effort:—that is to say diversity of production accompanied by unremitting and intelligent exertion.

And perhaps you will allow me in this connexion to observe that, in the present hard struggle for existence, it is not enough to produce many things, or even to produce many things well, but we must learn to produce them better than our competitors. It is only by being a little superior to our neighbours in this respect that we can expect to survive; or, as a matter of fact, that we shall do so.

The majority of the exhibits collected here are destined, I understand, to do further service at New Zealand, when I trust they will prove of interest to the manufacturers and others of that Colony. There is one point at least upon which those who may represent Fijian exhibits at Dunedin can do some service. The point to which I refer is the fact that Fiji produces the finest cotton in the world, whether it be that known as the Sea Island variety or the less valuable Upland cotton. This latter variety can be cultivated here with much ease and little or no risk.

With the help of inexpensive machinery, it can be prepared upon the spot so as to be worth about £37 per ton in the local market. You are aware, no doubt, that this cotton has brought in the English markets during the current year, one penny and a fraction per pound higher than a similar class of cotton received from other sources, and that it has been sold in London at the rate of £85 per ton.

I think therefore that it might not be without advantage, Mr. Mune, if it could be made known that the culture of cotton is at least as profitable as that of New Zealand flax. And that this Government has at its disposal a very considerable area of land, situated in various parts of the group, which it is prepared to lease upon long terms and a nominal rental conditioned upon the occupation of *bona fide* settlers.

With these few remarks, and the expression of my continued good wishes for the success of the Agricultural and Industrial Association of Fiji, I now declare the Exhibition to be open.

The Gubernatorial party then went through the show which was inconveniently crowded, and a detailed account of which we are unavoidably obliged to hold over for a future issue.—*Fiji Times*, Nov. 13, 1889.

EXPERIMENTS IN CEYLON WITH COCONUT LEAVES FOR GAS.

(Communicated.)

In your article on "Bye Products," (see page 841) on 10th May you mention the uses to which the leaves of the palmyras and coconut trees may be applied. You may not be aware that at the request of the late Mr. David Wilson, Mr. Grinlinton tried experiments in making gas from the leaves of the coconut tree, and had some tons delivered at the Gas Works for this purpose in 1873 and '74. The gas made from the leaves, as also from coconut shells, which latter were used on many occasions, was excellent—in fact of the purest quality; but Mr. Grinlinton could not get the shells in sufficient quantity to enable him to count on a permanent supply to an extent which would make the product a financial success.

The leaves burnt up so quickly in the retorts that 5 tons disappeared in such a short time that it would hardly have been possible to supply the quantity of gas required for *one night*, from all the surplus leaves which could be collected at Colombo and delivered at the Gas Works in a month.

I mention these experiments to shew you that even in Ceylon we have not been slow in making experiments with our "Bye Products."

You know the practical use to which Mr. Grinlinton applied the Ammoniacal Liquor, made at the Gas Works for several years, at his Manure Works and the success attained there.

The use of coconut leaves and coconut shells in the manufacture of gas, I never thought would be a success financially, as there are no valuable residual products such as tar and coke such as we have from coal used in the manufacture of gas.

TEA-PLANTING has made such strides in the Azores, and the picking of the leaf is expected to be so considerable this season, that the pioneer shipment will this year be made to the London market. It is affirmed that Madeira tea will, in point of flavour, beat the China leaf hollow. It was only a decade ago that the tea plant was first introduced into the Azores by the Governor of Macao, who made several shipments of the plant from almost all the tea districts of China. A few years afterwards hearing that the plant was already acclimatized in the islands, he sent a few Chinese tea-planters to Madeira, who taught the natives how to manipulate the leaf.—*Madras Mail*, May 7th.

THE NORTH WYNAAD and Manantoddy Syndicate, Limited. has been registered in London by Mr. Henry J. Bethell, 20, Abchurch-lane, E. C., with a capital of £10,000 in £1 shares. The object is to acquire on such terms as the directors of the company think proper concessions or interests in land, mines and hereditaments in India.—*M. Mail*, April 24th.

COFFEE.—The *Batavia Nieuwsblad* says that the Java coffee crop this year will fall so short as to give rise to serious financial difficulties with the Government. The paddy crop too looks unpromising, and the sugar yield is no better. A deficit in the Budget looks alarmingly near, but the diminished taxbearing power of the impoverished people allows no hope of additional revenue.—*Penang Chronicle*, April 19th.

DARJEELING.—More rain I am glad to say, good steady and business like. As I am writing (Thursday evening) it is coming down quietly and persistently as if Jupiter Pluvius intended to make up for past deficiencies in this way. The influenza epidemic reached us in due course, and pretty nearly everybody, including your correspondent, has had it. It is not a pleasant disease while it lasts, and certainly does not tend to put one in charity with all mankind.—*Indian Planters' Gazette*, April 22nd.

EASTERN PRODUCE and ESTATES COMPANY.—The full Report and Statement of Accounts of this Company so intimately associated with Ceylon will be found given on page 839. The figures given show the importance of this Company which holds estate property in this island to a value exceeding £400,000. It is satisfactory to see that the Company has had a prosperous year and we think the prospects are good, in view of the very judicious management which the Company's experienced Colombo and Plantations' staffs give to its affairs.

A new process of **SALT MANUFACTURE** has been discovered by Dr. Sigismund Pick, of Szezakowa, Austria, who has for many years devoted his attention to the subject in connection with the manufacture of chemicals. Many people will be surprised to learn that in England salt is still manufactured in the way that was originally used—namely, by evaporating brine in open pans. Dr. Pick's process is to reduce the surface of evaporation and at the same time to decrease the amount of fuel consumed. With this purpose he has altered the shape of the pans, and has contrived a system of chambers, in which steam is forced, and after having performed its functions in one chamber is transferred to another. The advantages of the new system are obvious. In the first place there is a great saving in fuel, especially where exhaust steam is available. The present consumption of coal in the ordinary pan process is stated to be 12 cwt. per ton of fine white salt. Even where exhaust steam is not available for the new process, the consumption of coal is less than 4 cwt. per ton of salt. Another important advantage is the absence of frequent repairs, and the small amount of wear and tear. These items alone, in the ordinary method of salt manufacture, add seriously to the cost of production not only in themselves, but by reason of the loss occasioned by long stoppages. Then there is the saving in labour. In Dr. Dick's system six men and two boys, formed into two twelve-hour shifts of three men and a boy per shift, are sufficient for working a plant having an output of fifty tons per day of twenty-four hours. Other advantages are the absence of smoke and deleterious vapours, and the great economy in space occupied. A fifty ton per day plant only occupies an area equal to that covered by a salt pan producing forty tons per week.—*O. Mail*.

MR. J. S. MIDDLETON of Mysore is a passenger home by the P. & O. S. S. "Ganges" after one of his periodical visits to his extensive cardamom properties. He declares Ceylon has brought down the average price of his staple product 75 per cent! Mr. Middleton is full of praise of the coffee under shade in Mysore and Coorg.

THE NEW SYSTEM inaugurated by Sir Lepel Griffin in the Ruby Mines Company is that 60 mine owners have now the right to mine, employing between them 420 men, and paying R20 per man per month to the Company, and all restrictions of every sort and kind as to the disposal of their produce are removed.—*M. Mail*.

A VERY LARGE "INDUSTRIAL DIAMOND" valued at 5,000 dolars was recently taken from Brazil to New York. It weighs 367 1-3 carats, is about two inches long, and looks like a chip of anthracite coal. This kind of diamond is so hard that it will not polish, and after being split up it is used to tip the drills employed in boring rock. It is only found in the Brazilian mines.—*Madras Mail*, May 8th.

THE TEA DUTY.—Messrs. F. S. Long & Co., writing on 3rd April, thus refer to the good results likely to ensue for Ceylon tea on a reduction of duty:—

The Budget, which is anxiously looked forward to, is fixed for the 17th inst. A reduction in the duty (which is a heavy tax on the average price of tea) would no doubt greatly stimulate consumption, and bring Ceylon tea within the reach of the poorer class, who are after all the great consumers of tea.

A PLANTING MACHINE.—The description of a planting machine is included in the annual report of the Department of Forests at Washington for 1888. The machine is drawn by horses and consists of a knife, which opens the soil to a depth of 16 inches to 20 inches, followed by a ploughshare, which removes the soil to a width of 8 inches. A rotating apparatus of the machine, holding cuttings, then moves forward and places the latter in the soil successively. Two curved plates relift the soil, and two bent wheels or rollers come finally into position and press against the plant. With this machine one man can plant from 10,000 to 15,000 cuttings a day. Operations have been carried on for the last two years with the machine and the experimenters are now able to report that seven-eighths of the cuttings inserted in this way succeed and become plants.—*Indian Agriculturist*, April 26th.

CINNAMON AGAIN.—*The Produce Markets Review* of April 19th, thus refers to Ceylon's old staple and still important export —

The neglect of cinnamon in this country is very singular, and our "good plain cooks" seem to know of no spice beyond nutmeg for flavouring the tops of puddings, tarts, &c. On the Continent, cinnamon is very largely used for such purposes and for similar ones, mixed with sugar or not. With the deadly monotony of ordinary British middle-class cooking, cinnamon would introduce a small element of variety, and that it has unsuspected virtues, possibly prophylactic against the microbes of Thames water, is shown by the following extract from *Tuesday's Daily News*:—"A discovery has been made which shows that the love of our ancestors for drinks spiced with cinnamon was fully justified. What were not the Dutch ready to do to procure cinnamon and other spices for their mulled wines, and what wonders of navigation did they not accomplish in their lumbering vessels in order to fill the spice-boxes of their house-wives? According to our Paris correspondent, Dr. Chamberland, M. Pasteur's chief assistant, has just discovered that cinnamon is fatal to the typhoid microbe, which must infest the sluggish waters of the Netherlands."

JAVA COFFEE CROP.—From a reliable source the report has been received that the Government's crop of coffee in Passarœan (Java), was estimated on February 1st at about 62,000 piculs, against 237,170 piculs on February 1st 1889. According to the estimates of the crop in the Eastern quarter of Java the production will be only 20 to 25 per cent of the quantity harvested in 1889.

MINING LEASES.—A contemporary is informed that the committee appointed by the Government of India to draw up rules for prospecting and mining leases held its final sitting on Monday, and that Mr. John Harris, the well-known mining engineer who has for some years travelled in India and other Eastern countries on prospecting business for Messrs. Nobel of Glasgow, attended the meeting. The committee, having had the advantage of advice from the delegates appointed by the Chamber of Commerce as well as from Mr. Harris, will now be able to issue rules more acceptable to the public than any which exist.—*Pioneer*.

The first arrival of the new crop of SUMATRA TOBACCO have taken place during the last few weeks, and a sale of 2,331 bales was effected on March 21st. The quality was considered very favourable, being light coloured, and of ripe growth. The leaf could be better and less spotted, but notwithstanding this the prices obtained for the two best parcels were c. 222 and c. 208 respectively. Among these parcels there was a good quantity of light fancy colours, and if the proportion of these colours will be larger in the present crop, it is questionable whether the high prices will be maintained, which, however, may lead to an advance of the present low prices for dark tobacco. There is still much agitation in certain circles in America to get a higher import duty on Sumatra tobacco. It is to be hoped that these efforts will not succeed. The Minister for Foreign Affairs in reply to a letter of a commercial firm in this city, dated March 26th, states that the intended increase of the import duty on Sumatra tobacco in the United States has been a matter of careful consideration of his Majesty's Minister at Washington, who does all in his power to promote the interest of the Dutch tobacco export trade. The Minister adds that this important matter will have the continual attention of the Government.—*L. and C. Express*.

CINNAMON IN DAYS OF OLD AND THE NEW DEVELOPMENT.—The following is the deliverance of *St. James's Budget* on Cinnamon as fatal to the typhoid microbe:—

The merchant-adventurers of the Renaissance who sailed from the Netherlandish ports to the distant places of the earth hankered after many things. Pearls from the ocean and gems from the mine were rarely out of their thoughts; the rich fabrics of the East were ever before their eyes; but there was nothing they coveted so ardently and so constantly as spices. Such commodities fetched high prices; and your fat skipper from Antwerp or from Amsterdam was "death on the main chance." And of all the spices which were to be found in far-away corners of the world none was higher in favour than cinnamon. The Dutch and Flemish housewives needed it for many purposes; their husbands thought that their mullied wine was undrinkable without it. There was somewhat of the same taste in England; and now those doctors in Paris who are so shamefully clever have just found out why all this was thus. It was not because the Dutchman and his British cousin were so particularly fond of cinnamon; but because it is fatal to the typhoid microbe which Dr. Chamberland, the ingenious discoverer of these things, believes must exist in the Netherlandish water-ways in rich profusion. The discovery is a useful one, if it may be depended upon; but the Dutchman of old was not the kind of man to worry himself about microbes. He just swallowed them and said nothing.

OUR EXPORTS.—Very nearly 116 million lb. of tea, 161,000 lb. cinchona bark, nearly 14,000 cwt. plumbago, 4,138 cwt. of coconut oil, some coir, cinnamon and coffee sum up the week's shipping business in Ceylon products.

FISH CULTURE.—Upwards of one million American whitefish have been propagated from ova by Mr. John Burgess at the Midland Counties Fish Culture establishment, Malvern Wells, the ova having been sent by the United States Fish Commissioners with the object of assisting Mr. Burgess in his efforts to establish this valuable food fish. The ova were hatched out with a very low mortality, and the young fish, which have just been turned out of the hatcheries into rearing ponds, are doing well. The landlocked salmon of America is also being acclimatized by Mr. Burgess with successful results, together with the rainbow trout of California.—*London Times*. [All the fishes named might be tried in Ceylon?—Ed. T. A.]

A HANDBOOK OF PRECIOUS STONES. By M. D. Rothschild. New York and London: G. P. Putnam and Sons, 1890.—The author defines a precious stone as a mineral, which "must be adaptable for jewellery or ornamental purposes, and must possess beauty, hardness, and rarity," and he refuses to draw a line between stones that deserve the title of precious and those to be placed in a semi-precious or lower category. He writes "All precious minerals used for ornamental purposes, from the diamond to quartz or chalcedony, may properly be termed precious stones." The various stones are dealt with separately, and full information respecting the composition, properties, and specific gravity of each is given. The physical characters and optical properties of precious stones are discussed at the beginning of this little book, and at the end is a table of hardness and specific gravity.—*Journal of the Society of Arts*.

ORANGE CULTIVATION ON THE NILGIRIS.—Besides the paper on Viticulture noticed by us, the other day, says the *Ooty paper*, Mr. Lawford has contributed one on the cultivation of the orange and other citrus trees in California. It is superfluous for us to dwell on the subject in detail, as the cultivation of oranges and lime on the Nilgiris, is carried on with marked success. Not an estate but grows scores of trees of this family, some of the very best varieties. They are planted either in avenues or scattered among the tea and coffee. Little of the fruit, however, benefits the proprietor as it is stolen and consumed by the coolies. On some estates orchards are formed and enclosed, excluding orange trees marvellously prolific. As an example, we may instance that at Billicul. The soil here is gravelly, but by years of preparation it has become rich and productive. The trees are umbrageous and healthy, sufficiently close to yield a dense shade, and when in blossom, the air is redolent with perfume, and cool even during the hottest part of the day. The fruiting season extends from November to February when the grove is a fine sight, every tree laden with thousands of the golden fruit, some of the branches so abundantly as to need propping up. The fruit at Billicul is mixed but mostly of the thick-skinned variety, juicy and sweet, but alas! the demand for it has always been insignificant, and basketfuls every year, that could find no purchasers, were buried as manure. Kotagherry and Coonoor have always enjoyed a reputation for growing good oranges, the former celebrated for a mammoth thick-skinned or "loose jacket" kind which cannot be surpassed if it can be equaled anywhere. The Cockburn family, old settlers at that station, have the credit of having introduced and acclimatized this splendid variety. It is now, however, met with in many other places on the Nilgiris. The fine orange trees which a few years back made Coonoor famous for the fruit, have gone out by reason of old age, but houseowners there were wise in planting a younger generation and so supplies of the fine fruit are kept up in that station. The Coonoor Ghaut estates are dotted with orange and citrus trees making a fine show when in bearing.—*Indian Agriculturist*.

THE COMING CARDAMOM CROP in the planting districts of Ceylon this year is said to be generally short: so far the exports are in excess of those to the same period of last year, the figures being 147,000 and 131,000 lb. respectively; but the comparison is likely to be the other way during the latter half of the year, if the news of a short crop now prove correct.

Two specimens of Gordon's "Forbidden Fruit," the curious double COCONUT of the Seychelles, were brought to the *Pall Mall Budget* office a few days ago by Mr. J. Troubridge Critchell, who had just received the nuts from the Mauritius. The fruit of the Coco-de-mer has a peculiar interest to the many admirers of the late General Gordon, who firmly held to the idea that the Seychelles were the Garden of Eden, and that this unique vegetable growth was the cause of the world's depravity, against which Gordon fought so bravely. The nut weighs twenty pounds, and measures twenty-five inches across. The palm on which it grows (*Lodoicea Sechellarum*) is 100 feet in height, and is only to be found on this tiny group of islands. Hundreds of years before the Seychelles were discovered, these nuts were washed up on the Maldivé Islands, and the wisacres of those days told the people that this sea-borne fruit had grown on a submarine tree, and that it had a mysterious power of counteracting poisons. Hence the name—Coco-de-mer. It is probable that Gordon met with allusions to this wonderful nut in Arabic MSS., and afterwards visiting the Seychelles, was struck by the beautiful and isolated group of islands and their double cocoanut.

NATIVE CULTIVATION IN PERAK is the subject of legislation such as is enforced through village Councils in Council. From a recent *Government Gazette* we quote as follows:—

Whereas, it is necessary to encourage the cultivation of bendang land in the State, it is hereby ordered as follows:—1. From and after the 1890, any registered owner of bendang land, or person holding under him, whose growing crops are damaged by fire or by vermin, notwithstanding the exercise of due and customary care and precaution on his part, shall be entitled to sue and recover damages from the owner of any adjoining or neighbouring bendang land, or person holding under him, who shall have neglected to clear and burn off his land, in the customary manner, should there be, in the opinion of the adjudicating Magistrate, reasonable grounds for the presumption that the damage occasioned by such fire or vermin is due, in whole or in part, to the omission so to clear and burn off such adjoining or neighbouring bendang land. 2. Cases brought under this Order shall be heard and determined by one Magistrate, assisted by at least one native Magistrate or Penghulu. 3. The word *vermin* shall mean and include rats, mice, and insects. 4. In districts or sub-divisions of districts, when requested to do so in writing by a majority of two-thirds of the Penghulus, or of the paddy planters, it shall be lawful for the District Officer to frame rules prescribing the dates on which the various operations of planting and harvesting paddy on bendang lands shall take place, and imposing penalties for breaches of such rules. 5. Such rules, after being approved and confirmed by the British Resident, and after publication in the *Government Gazette*, and after being posted up in the Malay language, for the space of a fortnight, on the mosque, or other conspicuous building or place in the villages affected thereby, shall have the force of Law for twelve months. 6. Such rules shall deal with the following subjects, and no others: 1. The dates on which nurseries, irrigation, planting out, fencing, and burning stubble shall be commenced and completed. 11. The nature and dimension of the fences, if any, and the portion of each fence to be completed by each planter, where bendang fields are contiguous.

THE TOTAL SHIPMENTS OF BARK FROM JAVA (both Government and Private accounts) for the year ending 31st Dec. are given by Messrs. C. M. & C. Woodhouse on 20th March as follows:—

	Amsterdam lb.	English lb.
1889 ..	4,839,370	= 5,274,913
1888 ..	3,666,028	= 3,995,970
1887 ..	2,905,785	= 3,167,305
1886 ..	2,172,394	= 2,367,909

FIBRE: YUCATAN HEMP.—We referred in a recent number to the collection of reports on the fibre industries of Yucatan and Bahamas by Mr. George Preston, which has been issued by the War Office. The cultivation of Yucatan hemp must be a lucrative business. Mr. Preston states that the Yucatan hemp farmers no longer live on their plantations, but in luxury in the city of Merida, their incomes having generally risen during the past year or so 200 per cent. House property has also risen for investment to "a fabulous extent." Before the hemp industry took a start (about 1873) cotton growing and cattle raising were the chief industries. Two or three years ago locusts destroyed the fodder crops, the cattle died off or had to be killed, the cattle are now imported. The first shipment of hemp amounted to only 900 bales. In 1888 213,882 bales were shipped. There are in Yucatan 200 hemp (or henequen) farms of all sizes, the largest running 30 machines and employing 500 people. The clear profits of many farmers amount to from 500 dols. to 2,000 dols. per day. The population does not increase, however, and the introduction of foreign labour is very difficult. Frequent change of temperature, rains, fogs, winds, general muddiness or dry dust, and a total neglect of all sanitary matters are the drawbacks to residence in Yucatan, and, "a short life and a merry one" is the general rule of conduct.—*H. & C. Mail.*

TRAVANCORE ADMINISTRATION REPORT FOR 1888-89.—A copy of this Report has just reached us. Commendable progress is generally indicated in the different departments. We make a few extracts of interest to Ceylon readers:—

Capture of elephants.—25 elephants were captured in pits by the Forest Department and 4 on the Cardamom Hills. Of the former, 6 died in the pits, 4 while under training from injuries received in the fall and escaped before the decoy elephant could be brought to the pit. Of the latter, 1 died while under training. Out of the 17 surviving elephants, 9 are tuskers and 8 cows, and these are reported to be doing well.

Teak plantations.—There was no extension of the Teak Plantations. But a sum of R5,000 has been sanctioned for opening new plantations in the current year.

A sum of R4,633 was expended in the year for the up-keep of the old plantations, and the Conservator of Forests reports that these estates are all coming of well.

Sandal wood plantations.—The small sandal wood forest of spontaneous growth at Arienkavoo is doing well and every care is being taken of it.

Reserve Forest.—Under the provisions of Regulation IV of 1,063 a second Forest reserve was formed in the central range in the year under report extending over 120 square miles.

CARDAMOM AND OTHER GOODS.—Out-turn of the crop.—The out-turn of cardamoms for the year and the price realized at the auction sale are compared below with those of the previous year:—

	Candies.	lb.	R.
1887-8	256	87½	1,36,147.
1888-9	175	139½	1,38,447.

Price realized.—Though the crop was smaller than that of the year previous, the price realized was more favourable, being R790 per candy on an average against R531 in 1063.

Correspondence.

To the Editor.

CEYLON TEA IN AMERICA.

New York, U. S. A., March 29th.

DEAR SIR,—Just before leaving London I wrote you saying that I was intending to visit New York while taking a holiday, as we are very anxious to see for ourselves what is taking place in foreign markets for Ceylon tea.

I feel sure that you, and Ceylon tea planters generally will like to hear what is taking place in New York in reference to the Ceylon tea industry. I am glad to be able to tell you that after seeing numerous people connected with tea here I find that very great efforts are being made to force Ceylon and Indian tea into consumption. I have come across various firms who sell considerable quantities of these teas. Many houses blend them with other teas and find a good and increasing business for them. There are so many firms now pushing them that even those firms whose interest lies entirely in China and Japan teas, and have on that account, no wish to see Ceylon or Indian teas introduced, are ready to admit that remarkable efforts are being made to increase their sale and that the industry will be a growing one.

The Ceylon Planters' American Tea Company have a shop in the centre of the fashionable shopping quarter, which is admirably situated, and is in addition so elegantly fitted up that I believe it cannot fail to attract considerable attention. The window is so planned as to draw the notice of passers-by—of whom there are a very great number, composed largely of the fashionable class, and the interior of the shop appeared to me particularly attractive and artistic. I believe that the Company is likely to do a good work for Ceylon and that although progress will at first no doubt be slow, the sale of Ceylon tea will be materially helped by the efforts of the Company, and by the manner in which they propose endeavouring to increase the sale. I was much pleased with all that Mr. Pineo told me of his work as well as all I heard from Messrs. Watson & Farr, and I think that they are fully determined to make the thing a success.

I will not now add more as you will doubtless hear detailed accounts of the Company—and probably too of the work which is being done by a section of the trade in pushing the sale of Ceylon tea.

I shall probably write you again from Montreal or other places through which I may pass in order to let you know my impressions of the condition and prospects of the Ceylon tea trade in these places. —I am dear sir, yours faithfully,

A. G. STANTON,
(Gow, Wilson & Stanton.)

ENGINEERING ENQUIRY AND ANSWER.

DEAR SIR,—With reference to Inquirer's letter in your issue of 12th inst., he will find a good deal of information bearing on the question in Goodeve's Elements of Mechanism. I do not think friction would be greatly increased by driving with a long endless wire and thus transmitting power to a distance. The chief loss in friction would be the additional weight of the wire and the extra mechanism which would have to be employed as these wires were employed are driven at very high rates of speed, which would involve suitable mechanism to reduce the speed where the machinery is such as tea rollers etc. Where the wire is driven at a very high velocity, a very slender wire can transmit great

power: in an instance given by Goodeve, a wire rope $\frac{3}{4}$ inch diameter run upon pulleys, each 15 feet in diameter and making 100 revolutions per minute, the pulleys are driven by 3 turbines and develop 750 horse-power. He goes on to say that "no less than 17 factories in different positions have been supplied with motive power from one set of turbines, and it is stated the total length of transmission is 3,300 feet." The rope travels at a velocity of about 53 miles an hour. It is important to bear in mind that the greater the velocity the wire travels at the less strain there is on it and with a slower velocity a much thicker wire would be required. With properly grooved pulleys there would be little or no loss from slipping. He also gives an instance where a cotton rope $\frac{3}{8}$ inch diameter and weighing only $1\frac{1}{2}$ oz. per foot is employed for actuating a crane adapted for lifting 25 tons. The velocity of the rope is 5,000 feet per minute which would be reduced by suitable mechanism to 1 foot $7\frac{1}{2}$ inches per minute and the requisite work would be done by subjecting the cord to no greater strain than that of 109 lb.—Yours truly,
SABARAGAMUWA.

CEYLON TEA IN LONDON.

13, Rood Lane, London E. C., April 11th, 1890.

DEAR SIRS,—We are in receipt of your favour of 12th ult. with enclosures and we now thank you for the suggestions contained, both in them and in the letter in your paper of 6th March, to which you refer us.

As regards the main suggestion in "Critic's" letter, that we should show the deliveries for Home Consumption, and the Exports separately, it will be seen on reference to our Circular of February 14th that we had anticipated it.

It is only since the commencement of this year that the Board of Trade separated the Exports of Indian, Ceylon, and China etc. tea, they having formerly been grouped under one heading, viz., "Exports of Tea." We think we may take the credit of first inducing the authorities to consider this alteration, as we have continually urged it upon them for some considerable period. These detailed figures are only obtainable about the middle of each month, and, as it is necessary for us to publish prompt information for our friends here, we cannot do otherwise than continue our tables as at present, in the earlier issues of each month.

Regarding the suggested new table, we appreciate the idea, and are considering the possibility of carrying it out.

The amount of tea destroyed as "unfit for food" is small, and we are glad to say as regards Ceylon tea, insignificant.

Again, referring to our Circular of the 14th Feb. the two tables contained therein which, according to your correspondent "appear to confuse matters," were given by us with a special object, which was mentioned in that Circular. The following table of movements of all tea from the London bonded warehouses during the year 1889, will show that the amount removed in bond to other warehouses though an important quantity was nothing like so great as your correspondent seems to suppose.

Deliveries of tea from London Bonded Warehouses	
	during 1889.
Duty paid from Warehouse :	159,920,427
From ship :	81,453
	<hr/>
	160,001,880 lb.

Sent coastwise under bond } for Home consumption }	25,313,291 l ^b .
Exported and Stores	35,779,457 "

For the year 1889, total 221,094,628 "
Again thanking you for the suggestions, and assuring you that they will have our most careful consideration.—We are, dear sirs,

GOW, WILSON & STANTON.

PLANTING IN THE LOWCOUNTRY.

Daphne, Udugama, April 21st.

DEAR SIR,—In your issue of the 17th inst. I notice some Planting Notes from the South* which call for a protest, as they seem to me to be not only verging on a libel on the planting community in the lowcountry, but also mischievous, as they are calculated to give those of your readers who are unacquainted with planting life down here a very erroneous idea of our daily routine.

It would have been better had "Knight of the Tea Bush" confined himself to the personal pronoun throughout, as he does when informing the general public of the amount of liquor he consumes per diem.

I have been planting in this province for the last ten years, and have not yet met the planter who could afford to spend his day as "Knight of the Tea Bush" describes.—I am, dear sir, yours faithfully,
S. E. B. CURTIS.

THE LARGEST TIC POLONGA.

The Residency, Point Pedro, April 26th.

DEAR SIR,—Could you or any of your readers oblige me by mentioning the length of the largest Tic Polonga killed in Ceylon. Yesterday the writer skinned a Tic Polonga which had killed a man near the village of Tunnailai, measuring 5 feet in length: would this be considered a large Tie.—Truly yours,
JAMES PRICE TODD.

[Tennent in his "Natural History of Ceylon" does not give the length of the "tic polonga," but Dr. Davy in his Ceylon Book published in 1821, says that "when full grown the tic polonga is from 4 to 5 feet long," so that Mr. Todd's specimen is a large-sized one. No doubt we have had records of larger specimens, but we cannot recall any at this moment.—Ed. T. A.]

THE COLOMBO Vs. LONDON TEA MARKETS FOR PRICES.

May 14th, 1890.

DEAR SIR,—As regards the Colombo tea market my experience is that while medium and common teas may perhaps command their value, it is difficult to obtain it for the higher classes of tea.

My broken pekoe has averaged 1s 3d in London since 1st January, while the same tea sold locally has only averaged some 61 cents equal (by Rutherford's table, at 1s 6d exchange) to 1s 1d only: A good margin for profit there one would think. I notice too that a break intended for shipment is usually valued considerably higher than one for local sale though not, it is only fair to say,

* Where did Mr. Curtis get this title? It is not in the contribution he refers to, but "Planting in the Lowcountry," which may be "Kalutara" or even the "Kelani Valley," while anyone can see that "Knight of the Tea Bush" was writing with a "kinder sarkastic" pen. However, there is no harm in Mr. Curtis's defending his brethren in case anyone should regard the "Knight" seriously.—Ed. T. A.

by the same broker. And, as a rule the valuations are borne out by results.—Yours truly,

HAPUTALE PLANTER.

[The period given by our correspondent—three or four months—is far too short to afford a safe test or comparison; and indeed we are aware it came after a period during which local buyers of fine teas had paid prices on which they lost heavily afterwards in London. A year's trial of the two markets is the least for a safe comparison.—Ed. T. A.]

GOOD COFFEE IN THE WALLAHA VALLEY

Lindula, May 19th.

DEAR SIR,—Maousella estate is not exceptional in its bearing qualities in the Wallaha Valley. Two other estates have given over 5 cwt. per acre last crop, without the aid of manure and high cultivation quoted as necessary by Mr. MacLachlan. The introduction of tea into the valley has greatly benefited the isolated bits of good coffee that have been retained and the tea itself is a sight worth seeing.—Yours truly,
X.

[This is good news: "good coffee" in most of our planting districts alas is a sight to gladden the eyes of the visitor as a relief to the generally ubiquitous tea-bush.—Ed. T. A.]

RIPE FIGS GROWN IN COLOMBO.—Our Parsee friend, Mr. Hormusjje Pestoujee has brought us a full size ripe fig grown in his Dematagoda garden, on a tree 6 months old, from seed brought down from Wewessa estate, Uva. This is good work, and Mr. Pestoujee is giving cuttings to several friends to spread the growth of figs in the Western Province.

THE EXPERIMENT of importing Brittany cattle into the Simla and Kulu Hill districts has been successful, in that the animals have found favour with the people; but the casualties from the prevailing rinderpest have been great. Three bulls and three cows have died. There are now three whole-bred and thirty-four half-bred animals in the two districts. *M. Mail*, May 12th.

THE CEYLON TEA PLANTATIONS COMPANY, LIMITED.—Another Big Dividend.—We learn that a telegram has just been received in Ceylon to the effect that the Directors of this Company have declared a total dividend for the year 1889 of 15 per cent. Considering the large capital on which this is paid—larger than that of Indian companies with a few exceptions—and the thorough state of efficiency to which all the Company's factories and properties have been brought, it is we think a feather in Ceylon's cap generally, and in that of that local Manager and staff in particular.—Local "Times".

THE ADULTERATION OF CHICOORY.—The United States Consul at Stettin in a recent report calls attention to the adulteration of the chicory exported from there. From inquiries which he made he learned that the larger part of the chicory is made from beet roots, dried and burnt or roasted, and prepared in the same manner as pure chicory. The mixture usually sold as chicory is composed of one-third of the pure article and two-thirds of roasted beet roots. It is invoiced at about 1½d per lb. a price at which it is quite impossible to get genuine chicory. But although he was able to put a stop to some extent to this by warning American purchasers and consignees, he observes that "it is not alone in this branch that we are being defrauded, but in many other branches as well. A merchant extensively engaged in the hardware trade casually remarked to me not long since that cutlery, buttons, needles, &c. were manufactured in Germany stamped with the trade mark of English firms, and exported to the United States as English merchandise, he at the same time praising the manufacturer for his shrewdness and business ability."—*London Times*.

THE OLDEST REGULARLY CROPPED TEA
IN CEYLON STILL THOROUGHLY
VIGOROUS.

LOOLE CONDURA FIELDS PLANTED IN 1869.

In successive issues of our "Handbook and Directory" in connection with our Planting Review, we have not failed to call attention to the good service done to the Colony by Messrs. Harrison and Leake, the partners in Messrs. Keir, Dundas & Co. and their faithful, intelligent Superintendent of Loole Condura, Mr. James Taylor. We refer more especially to their pioneering work with tea; although cinchona might also be mentioned. So early as 1865, Mr. James Taylor by Mr. Harrison's orders, began collecting tea seed from Peradeniya and he put out the plants along the roads and paths in Loole Condura in the following season. In that same year (1866) Mr. Leake, as Secretary of the Planters' Association, moved that body to get Sir Hercules Robinson to send Mr. Arthur Morrice, an experienced coffee planter, on a mission to Assam to inspect and report on the tea districts. As one result, Mr. Leake was induced to order for his firm a consignment of Assam hybrid tea seed—the first probably ever imported into Ceylon—and this seed was also handed over to Mr. Taylor on Loole Condura. Mr. Taylor's first clearing for tea—20 acres—was felled towards the end of 1868 and this is decidedly the earliest planted field of Assam-hybrid tea in Ceylon. It is respecting this field that we have at intervals made inquiries as to the condition and bearing qualities of the bushes. Here is the answer to our latest application prompted by the desire to give the required information in our new "Handbook and Directory." Mr. Taylor replied in the following satisfactory way:—

To the Editor, *Ceylon Observer*.

The Oriental Bank Estates Company, Limited: Loole Condura, April 28th.

DEAR SIR,—Your note of 25th received. The original field of Assam Hybrid Tea here, planted in 1869, is still a thoroughly vigorous and healthy field of Tea.—Yours faithfully, JAMES TAYLOR.

We have in edition after edition of our Handbook acknowledged the great debt which this Colony owes to the proprietors and managers of Loole Condura, in connection with the tea and cinchona planting industries, and we may be allowed to repeat on the present occasion and in our daily columns, a recommendation made in the volume referred to on the last occasion of our alluding to the subject:—"To Messrs. Harrison and Leake of Messrs. Keir, Dundas & Co., and their intelligent and industrious manager (Mr. James Taylor) on Loole Condura belongs, therefore, a chief portion of the credit of starting both the tea and cinchona enterprises successfully in Ceylon. As an acknowledgment the Government ought, at least, to give free grants of land to these gentlemen."

SUNSTROKE, HEATSTROKE, AND HEAT
EXHAUSTION.

Sunstroke, *coup de soleil* and insolation, are synonymous terms, indicating a train of symptoms of a very grave nervous disorder brought about by exposure to the powerful heat of the sun. In sunstroke the patient becomes giddy, feels a "rush of blood to the head," and falls, becoming rapidly unconscious. The pupils are contracted, the pulse hard and quick, the skin hot and dry, the face red, often cyanosed, the carotids throb visibly and the respiration is laboured and coma rapidly ensues, and death often follows in a few hours. Certain conditions predispose to sunstroke. The full blooded, shortnecked, florid European in the tropics is a likely subject. Exposure to the sun after indul-

ging in alcoholic stimulants or engorging the stomach, favours this condition. Those in whom the nervous system has been much lowered by exhausting forms of disease are particularly prone to suffer from this malady. It is common in India among soldiers and sailors who imprudently, and with little knowledge of the fearful risk they court, after a heavy meal and tolerably free potations of beer, saunter out into the bazaars, to be brought back unconscious, comatose and dying from sunstroke. It occurs often as an unexpected complication in the course of ordinary remittent summer fevers, when the heat has been severe. It is strangely true that exposure to the sun's rays is not a necessary factor in producing heatstroke or heat apoplexy, as it is sometimes called. This condi-

THE HEALTH OF THE SKIN.

The surface of the body comprehends a space of about twelve square feet. When it is taken into consideration that the skin is a breathing organ as well as are the lungs, though in less degree, we begin to appreciate its importance. Besides this the skin performs an important function in the way of perspiration. Of the many quarts of fluid that pass out of the body in twenty-four hours, fifty per cent passes off by the kidneys, thirty per cent by the lungs, and twenty per cent by the skin. Then the skin is constantly secreting an oil and excreting substances that are injurious to the body. Its surface is covered with a tiny film of oil; beneath the oil are the horny scales, which come off as scurf. The oily film and the scales protect the underlying tissues. If the oil be removed, the skin is more sensitive to atmospheric influences, irritating gases, and the like; hence it is that those who use much soap, and then are exposed to a cutting wind, find the skin chapped, reddened, and inflamed, for the action of the soap tends to remove the oil from the surface of the skin, and with the oil the dirt. In this connection reference may very appropriately be made to Lanoline Soap. This is a pure neutral soap, containing Lanoline, the design of the Lanoline being to minimize and prevent the action of any alkali set free when the soap is dissolved. Physicians speak of it in the terms of highest praise.

There is a function peculiar to the skin which is seldom or never taken into account, and that is its contractility. The number of tiny blood-vessels, microscopic in size, that permeate the twelve square feet of skin covering the body are counted only by billions. If the skin be weakened, these vessels are dilated, and the internal organs of the body supplied with less blood. When the skin is burned or largely ulcered, there is great difficulty with its healing, and this difficulty is largely attributable to the lost contractility. This fact accounts for ulcers upon the legs having been cured by bandaging. Those whose face and hands are prone to become very red will find in this paragraph an explanation of the redness, and they should bear in mind that a free application of a bland and natural unguent to the skin will afford them the best means of prevention. Lanoline Cold Cream answers this purpose well. It is a delicate, emollient, creamy product, of pleasing fragrance, and is delightful to use. It never turns rancid, and never irritates the skin. It is composed primarily of Lanoline, a fact found in hair, horns, nails, and the horny layer of the skin. Lanoline differs from all other facts in that it is constituted of cholesterine with a fatty acid instead of glycerine, with a fatty acid. Lanoline Cold Cream never turns bad, is absorbed by the skin at once, does not run like ordinary ointments, and is slightly adhesive, so that it can be applied to mucous surfaces for cold sores.—"Health," London.

tion is dependent entirely upon the over-powering morbid influence of heat on the great nerve centres. Contrary to the popularly accepted opinion that direct exposure to the sun is essential to the production of sunstroke or heat apoplexy, it is a conspicuous fact, that this malady is of most frequent and fatal occurrence in hot and steamy weather, when the atmosphere seems too thick to be breathed, when the buttoned coat and the stiff linen collar seem a positive burden, when the European envies the loose flimsy garb of the Indian, and wishes that fashion would relax its cast iron rules and permit of comfort and ease in the art of dress in India. In such days we have cases of sunstroke or heatstroke as it is more appropriately termed, taking place in those who have not ventured out of doors for a moment. They occur in the barrack room, in the tents of our military camps when quarantine is being observed, in the sheds along for wharves, in the 'tween decks of ships in our port, in the most sheltered, sultry places, but chiefly in confined, ill-ventilated rooms, where there is no play or fresh air. Heatstroke, though a dreadful malady, is fortunately preventible. Precautionary or prophylactic measures are sufficient to lessen and even to remove the risks of the occurrence. Light, loose clothing, the disuse of tight collars especially, light meals, a free state of the bowels, sufficient protection to the head while out of doors by means of a light double-chambered ventilated helmet or sola-bat, and the usual Anglo-Indian contrivances for keeping one's room cool by means of punkabs, tatties and thermantidotes. The free use of drinks made from the sub-acid fruits so common in the country (limes, tamarind, pomegranate) are not only grateful and delicious but absolutely cooling. Their refrigerant action calms the heated and excited circulation, and affords a salutary protection against the enervating effects of the sun's heat. All alcoholic stimulants ought to be most rigidly eschewed. The treatment of a case of sunstroke may be summed up in three words; reduce the temperature. It is the excessive heat that kills, by paralysing the heart. Loosen all the clothing, put ice or cold water to the head. If possible, strip the patient of all clothing and douche the whole body with cold water, apply ice to the spine, administer a copious clyster of warm soap water. If the stomach is gorged, give an emetic of mustard, sulphate of zinc or ipecac powder. Large half ounce doses of the liquor ammonia acetatis act beneficially in lowering the temperature, while they prevent the prostration that is almost inevitable. When the head and face are much cyanosed, the prompt application of a dozen leeches to the temples minimises the danger of cerebral effusion and death.

Heat exhaustion is a totally different condition to heatstroke, and it would be serious to wrongly discriminate between the two. While dependent upon the same morbid overpowering influence of heat, it is when considered with sunstroke, a comparatively mild affection. It occurs chiefly in ill-conditioned children, in weakly persons who have much mental work or worry, and in hysterical women. It does not differ in its symptoms from other conditions of acute exhaustion. Presenting itself when the heat is oppressive it is likely to be mistaken for sunstroke by the uninitiated. The manifestations are diametrically opposed however. The face is blanched and covered with a clammy perspiration, the pupils are dilated, the pulse quick and thready, the breathing is gasping, and the expression one of death-like ghastliness, with a marked tendency to syncope. The use of gentle diffusible stimulants, absolute rest, freedom from all nervous excitement, with the restorative action of nutritious soups and pruels make recovery an easy matter in twenty-four hours.—*Medical Record.*

THE KOLAR GOLD FIELD, S. INDIA.

APRIL RESULTS.

Mining operations at the Kolar Gold Field were greatly interfered with last month by the prevalence of influenza among the miners. A large number of coolies yielded to panic, and returned to their homes in Malabar and elsewhere, and of those who remained

on the field, a large proportion were incapacitated from work for several days, and many of them are not yet convalescent. There was also much sickness among the English and Italians. The month was thus in some respects the worst that has been experienced since mining operations were commenced by the Companies now on the field. Heavy rain has lately fallen, and materially reduced the temperature, which ranged very high during the greater part of last month, and the general position of affairs is now improving, so it is hoped that the coolies who took to flight will soon return. The following are the returns of three of the mines last month:—

OOREGUM.—966 tons of ore were crushed, and yielded 2,049 oz. of gold, or at an average rate of 2 oz. 2 dwt. 10 grs. of gold per ton of stone. In March 2,075 oz. of gold were obtained from 1,005 tons of ore.

BALAGHAT.—305 tons were crushed, of which 105 tons were quartz, yielding 197 oz. of gold. In March 335 oz. of gold were obtained from 140 tons of quartz.

INDIAN CONSOLIDATED.—Eastern Section.—613 tons of quartz were crushed and yielded 150 oz. of gold.—*M. Mail, May 7th.*

NOTES ON PRODUCE AND FINANCE.

Mr. Goschen's Budget has not delighted any one in particular. Indeed, it has angered the tea trade because it was accompanied by comments upon the large profits made by the middleman in tea. Middlemen of all kinds are sensitive on the subject of profits, and they resent any mention of their gains, more particularly when the statement is not strictly accurate. That part of Mr. Goschen's speech, in which he referred to the working classes paying from two to three shillings per pound for tea which does not cost more than a shilling, was, it is urged on behalf of the grocer, an over-statement of the case of the consumer, who is now better able to take care of himself than formerly. In the eagerness to combat the allegation it is stated that the great bulk of the tea consumed in England is at present retailed at 2s. per pound, and this costs the retailer 1s. 6d. to 1s. 8d. per pound, the mean profit being 5d., or about 20 per cent., which, it is argued, is not an excessive profit considering the labour and expense involved in its distribution.

This percentage of profits is moderate enough, but it is not every retailer who is content with it. Mr. Goschen stated in the House of Commons on Tuesday night, during a discussion on the Budget, that he had made enquiries in the East-end of London as to how tea was sold. He had ordered a quantity to be bought at various shops in "ha'porths," and as a result it was found that the tea realised from 2s. 8d. per pound to 5s. In every case a half-ounce was asked for, but the reply was, "We can't sell half an ounce, but you can have a ha'porth." That, he remarked, showed that the organisation and distribution was not in a satisfactory condition; but it also showed that the retailer had it in his power to make the whole of the concession to the consumer.

The question of the profits made upon tea from the time it leaves the garden until it reaches the consumer is a delicate one. Planters and importers, we know, do not reproach themselves with securing too large a share. The wholesale dealer protests that his modesty on the subject of gain verges on philanthropy, and the retailer—well, it is unkind to question his action in the matter. Yet everyone knows that there is a wide margin between the price which tea fetches in the Lane and the sum charged for it per lb.—say at Slocombe Pogis, and even in the East-end of London, and it is not difficult to determine into whose profit that margin finds its way.

But sweeping condemnation is rash. Some dealers, grocers, and packet tea proprietors are content with reasonable profits, while others are greedy. China tea can be purchased in bond for, say 4½d., and sold at 1s. 8d. Some Indias and Ceylons, upon which the profit is smaller, may be obtained at, say 8d., 9d., or 1s., and sold at 2s. to 2s. 6d., or, say a blend which costs the retailer 1s. 6d. or 1s. 8d., duty paid, sells at 2s. 6d.

Surely this is a profit which should more than satisfy any retailer and one that may be reasonably called large. But it depends on the locality. In some districts the price of tea is cut so fine that the profit is small, and out of all proportion to that obtainable in others, but in too many cases the retailer makes a large profit if he knows how to blend and "fetch up" his tea, and sell it by the "haporth," although since India and Ceylon teas have been in demand it is more difficult to make these large profits.

Will the grower benefit by the reduction of duty? We think this very unlikely. The duty on cheap teas has been proportionately much higher than on dear teas. The market prices, apart from the duty, have been averaging on Ceylon teas about elevenpence, on India teas tenpence, and China teas sevenpence per pound. Now the sixpenny duty was consequently nearly 100 per cent. on the China teas, whereas it was only 50 per cent. on India and Ceylon teas. The question now asked in the "Lane" is—"will the reduction of the duty by making the cheap teas cheaper cause a greater consumption of them?" Yes, and in that case it will be the cheap China teas that will mainly benefit by the reduction.—*H. & C. Mail.*

THE TEA TRADE IN AMERICA.

Brief mention was made in our last issue of changes in the relative consumption of beer, tea and coffee and which deserve further consideration. The use of malt liquors increases steadily from year to year, having risen in five years from 10.6 gallons per capita in 1884 to 12.4 gallons per capita in 1889. If we study the imports of tea we find that the per capita consumption is decreasing and is less than five years ago. In 1889 it was 1.23 pounds per capita, against 1.36 pounds in 1888; 1.46 pounds in 1887; 1.35 pounds in 1886. For the six years 1884-89, it averaged 1.27 pounds, against 1.36 pounds per annum from 1878-83 and 1.34 pounds from 1870-75.

Ordinarily, the cheaper an article the greater the consumption, but as regards tea, we find a lower per capita consumption when prices are low than in former years, when tea paid a duty, and subsequently when prices were nearly double those now ruling.

Taking the average import price at the point of exportation, let us compare the per capita consumption of tea for a series of years, as follows:—

Year.	Cents.	Pounds Per capita.
1880	27.4	1.39
1881	25.7	1.54
1882	24.6	1.46
1883	23.5	1.28
1884	20.2	1.10
1885	19.5	1.15
1886	19.6	1.35
1887	18.7	1.46
1888	15.8	1.36
1889	15.9	1.23

This table indicates lower prices, poorer quality, decreasing popularity. The per capita consumption of coffee in 1870-75 averaged 6.9 pounds, against 8.7 pounds per annum during the six years 1884-89, a gain accomplished in spite of a rise from a period of low to high prices. The use of beer, as previously shown, has also increased per capita. Why, then, has the use of tea declined?

Largely we believe because retailers have pushed the sale of cheap tea. They do not appreciate as they ought the value of flavor in the cup, paying too much attention to style in the hand. The result is disgusted consumers, a dwindling trade, smaller profits. The tea department should be one of the most profitable connected with a retail grocer's business. It is useless to argue that people will not pay for a good article. The consumption of tea was on a larger scale fifteen or twenty years ago than now, although the general conditions of business were far less favorable than at present. Wages were lower, food of all kinds more expensive. We were passing through a period of unusual depression, the result of the Civil War. In 1873, line prices of Japan tea ranged from 30 cents to \$1.15 per pound; Oolong from 28 cents to \$1.10; Young Hyson from 30

cents to \$1.20. The best grades sold at retail for \$1.50 per pound. And that year the per capita consumption of tea was 1.53 pounds. In 1889 the average price of medium to fine Japan tea was 13½ to 19 cents; choice 23 and 24½ cents per pound, the range from 15 cents for common to 50 cents for finest; Oolong ranged from 15 to 60 cents; Young Hyson from 14 to 65 cents. Undoubtedly there has been a general decline in the cost of tea, but if there had been no depreciation in average quality the consumption should have increased as it has with coffee and beer.

In 1870-72 nearly one-half of the tea imported at New York was China green, the relation of the different kinds comparing with the exports to United States and Canada in 1889 as follows:—

	1872.	1889.
Green	19,998,339	14,750,000
Black	16,135,194	25,250,000
Japan	12,500,000	40,000,000
Total	48,633,583	80,000,000

In the Chamber of Commerce report on the tea trade in 1889 we read that the higher lines of true Moyunes and Tenkai chops were scarce, and that prices advanced, while the bulk of the stock was unattractive and freely pressed at auction. As to Japan tea, it says: "Consumption appears to be leaving the higher grades of Japan tea more and more, and becoming concentrated upon 'tea for price,' the average buyer having little use for tea above 20 cents, and aiming chiefly to secure best possible value at or under 15 cents."

As to Oologs, we read that Formosas above 20 cents (cargo price) were scarce in New York. In short, fine teas in this market were scarce throughout the season.

The desire of jobbers to purchase "tea for price" is the result of the retailer's demand for "tea for price." There is a mania for a fifty cent tea or one of less cost. Dealers push the trade in cheap tea and the result is dissatisfaction and a lessening of the number of consumers. A few keep the best teas the market affords and cater to people with a fastidious taste, making tea at \$1 a pound their leader. This is the true policy—Quality not price. Let strength and flavor be the two considerations; eschew and never put in stock damaged tea and do not keep cheap teas. Those who have been the most successful in building up a tea trade never put a poor tea in stock. Even in tenement house districts the better qualities are the ones most sought after. A grocer who is a good judge of tea always commands a large trade in the article.

Grocers, your competitors, the planters of Ceylon and India, understand this. They are pushing for the tea trade of the United States. And how? They crowd the sale of tea at \$1.25 per pound and emphasize the point that one pound of good tea at that price will go as far as the same amount of money spent in a 50-cent tea. They advertise that: "Good tea does not come from China or Japan; the good teas of those countries do not come here." That is a partial truth, for good tea does come from China and Japan, but the bulk of our imports are of the lower grades, because grocers crowd their sale and are injuring the business. The Inspector-General of Customs at Peking, Mr. Robert Hart, in a report on tea, says: "Not only is China the native place of tea, but Chinese tea is superior in flavor to all other teas." And yet England takes Indian teas and America 50 per cent of Japan, because China teas are not prepared with care, the gardens not properly cultivated and the curing and packing carelessly done, and the lower grades made the bulk of the exports.

The grocer's tea trade will rise or fall as the grade or quality is high or low. If he is not a good judge he can secure the services of an expert and maintain a high and uniform standard of quality. A high price always carries with it a guarantee of quality, and therefore tea at \$1 per pound will make more trade than tea at 50 cents per pound. That is the true way to meet the competition of the dealers who give away diamonds and watches with tea or who connect any sort of prize system with the tea department. Quality will always win and is the only thing which will secure a permanent trade in the article.—*American Grocer.*

THE TEA TRADE.

NEW YORK, March 23rd 1896.

Editor *American Grocer*.

In commenting on your article concerning the tea trade in your issue of Feb. 26th, I am inclined to think that your conclusions regarding the falling-off in consumption, are not entirely carried out by the figures given; in fact, it is hardly safe to base any conclusions concerning the trade on statistics obtained in relation to a free article, as such statistics must necessarily be more or less unreliable. But even on the figures you give, I notice that while 1889 apparently shows a slight falling off, 1888 was above the average of the past ten years, and 1887 was, with the exception only of 1881, as large as any mentioned.

These figures, while hardly showing a falling-off, certainly do not show an increase in consumption, a fact which I think is fully accounted for by the figures in your table of prices for the past ten years, the tendency of late years being more and more in favor of "tea for price," regardless of quality. Consequently, the claim of the Ceylon planters is somewhat true, that good tea does not come here from China; but will good tea continue to come from Ceylon? certainly not for any longer period than may be necessary to give it a footing in this country; then it will join the ranks of "tea for price," and eventually only the low grades will come forward.

It is quite evident that China teas cannot, with the present heavy inland taxes and export duty hold their own here in the competition for price. The final outcome of this must surely be that China teas will be driven to the wall. Thus it is that we see the result complained of in the report of Mr. Hart, inspector of Customs at Peking, 'that England takes India teas, and America takes 50 per cent. of Japans.' This falling off in both quantity and quality of China teas becomes very apparent when we ask what has become of those crack chops of Moyune Greens from the Shanghai district and the formerly well-known chops of Oologs from Foochow. The former have been displaced by the inferior products of the Ping Suey district, now so much in favor here, and the latter have become so much reduced in quality as to no longer resemble the original article.

Therefore, it cannot be surprising that Japan teas should have come so generally into favor, when we consider that even the lowest grades of these are good and wholesome, whereas the best of Ping Sueys are really unfit for use as a beverage.

As to the cause of this demand for poor tea, I think it can be traced directly to one source namely that crockery-dealing nuisance known as the "tea store." The grocers themselves are not responsible for this wrong, but have been forced into it by the competition of these prize distributing concerns, and until consumers acquire sufficient wisdom to see the folly of furnishing their pantries at the expense of their stomachs, there can be little hope for any improvement in quality.

It is rumored that Congressional Legislation is about to be invoked in favor of a chemical test by the Custom House examiner of teas, and should this measure be passed, we certainly would be freed from much of the wretched stuff that is constantly being poured in upon us from China, under the present loose system of arbitration by merchant appraisers. But to materially increase the importation of good sound tea, the Government should impose an import duty of 12c per pound which would render the importation of very low grades much too risky for safety, and this would also put an end to the absurdity of retailing tea at the rate of 3 pounds for \$1, which, when compared with the present prices for coffee, is entirely unnecessary, and destined in the end, to prevent any increase in the consumption of tea.

R. E.

[The above expression of views comes from one of our importers. We believe a tax on tea desirable. The statistics we quoted are from Government reports, which are sworn to. We find that the records of private statisticians vary slightly from those of the Government. It is a step in advance that the Chinese authorities and tea men are fully acquainted with the steps necessary to secure an increased export of fine

teas. It has been brought to their attention that methods of preparation must be improved and that the taxes must be readjusted. Sir Robert Hart in his report says:

Quality, however, is a very important factor and all that is said about it merits serious consideration. Although quality necessarily differs from year to year and with the producing localities it is nevertheless true that preparation has much to do with it; care in preparation may possibly convert indifferent material into reasonably good tea, but carelessness will assuredly spoil the very best leaf. Comparing the tea of present and former times, the defects the merchants complain of are these:

1. Too long an interval is allowed to elapse between picking and firing; the firing is inadequate; and while the tea is deficient in strength and loses its flavor, it also does not keep.

2. Spoiled leaves are not rejected but are packed with the good, and the consequence is that the good are also damaged. Too much dust is put in each box, and the whole is sometimes further adulterated by the intermixture of the leaves of other plants.

3. The boxes in which tea is packed are not strong enough or well enough made for its protection.

4. The tea when delivered is often not up to muster. The remedies recommended are as follows:

1. There ought to be a sufficient depth of soil where the tea shrub is planted, and the ground ought to be weeded and manured.

2. The tea shrub ought to be well cared for; pruning ought not to be neglected; aged shrubs ought to be removed, and young ones planted instead.

3. All the leaves should not be removed from the same shrub at the same time, but only such as are ready for gathering. The leaves which are ready ought to be picked from all the trees in the plantation at the same time, and each picking ought to form a separate chop. The leaf ought not to be picked too soon or too late: although a ten days' overgrowth gives an increase of 25 per cent in weight, it causes a decrease of 35 per cent. in value. In India there are as many as sixteen pickings; that is, each shrub contributes sixteen chops.

4. After the leaves are picked, the subsequent processes—withering, rolling, fermentation, firing—ought to be at once proceeded with. The greatest care should be exercised at each step, and the leaf ought to be well protected from the weather, especially just after picking and while awaiting the other processes.

5. The inner and outer cases in which tea is packed ought to be more solidly made and more securely closed.

6. Musters ought not to be sent on ahead of the chops.]

TWO CEYLON PLANTING COMPANIES:
COFFEE—COCOA—CINCHONA—TEA.

In the home papers by the present and previous mails, our planting enterprise has come rather prominently under notice through the publication of the Reports and proceedings connected with meetings of the Ceylon Tea Plantations and the Eastern Produce and Estates Companies. Both of these associations are possessed of very extensive interests in Ceylon, and the results to their working indicate very clearly the progress and prosperity of the tea industry which now forms the staple enterprise of this island. The conditions under which the Reports of these two important Companies had to be drawn up, differ very widely. In the case of the Tea Plantations Company it was possible for the directors to announce that, for the third successive year, its shareholders would be paid a total dividend of 15 per cent. Thus within the short space of three years, the fortunate investors in this speculation will have received by way of dividend a sum closely approaching to fifty per cent of the amount of their investment. When we turn to the other Company, that by which the old Ceylon Company has been

superseded or resuscitated, we find the effects still visible of the disastrous time during which king coffee was deposed and tea was but commencing that career of success which has enabled it to successfully succeed to the deposed monarch.

Although it is the fact that the shareholders of the Eastern Produce and Estates Company—in striking contrast to the Ceylon Tea Plantations Company—have to content themselves with hope deferred as yet, it may well be maintained that they are rapidly approaching the time when they may reap very fully the advantages for which up till now they have had patiently to wait. We need scarcely refer in detail to the conditions under which their investments were made; but as some of our readers are comparatively new arrivals in the Colony, or have but recently acquired a local interest, it may be as well to review briefly a little bit of our past island history and the tragic events which led up to the formation of the Eastern Produce and Estates Company. The Ceylon Company Limited was established in the year 1864. It was then rumoured that facilities rather too readily granted by the Oriental Bank more particularly in Mauritius, had led to that institution being hampered in its operation owing to a large extent of estate property being thrown upon its hands. The Ceylon Company was avowedly formed for the purpose of relieving the Bank from a responsibility which the home directors felt was not one that it was legitimate for a Bank to undertake; but instead of fairly calling the Company after the Colony with the properties mainly to be taken over, the brilliant idea was adopted of buying up the splendid coffee properties of the Messrs. Worms in Ceylon and so calling the new Company solely after the island that was then by far the more prosperous of the two. Afterwards many more estates in Ceylon were taken over by the Company.

For a good many years the Ceylon Company had a career of uninterrupted prosperity. During that period the dividends paid by it were never, we believe, less than 12 per cent. To these halcyon times succeeded others which showed a great falling-off in Mauritius and then came the days which witnessed the ruin of so many of our own coffee planters. For years the directors struggled on, being generally supplied with funds by the parent Bank, until, on that institution suspending its operations, the Company's indebtedness to it was enormous, and no course remained but to wind it up. It is on the ruins of this Ceylon Company that the Eastern Produce and Estates Company has been built up. Succeeding as the latter has done to a bankrupt concern, to properties which had suffered greatly both by enforced neglect of full and proper cultivation and having absolutely no produce, the new Company had necessarily to proceed with the utmost caution and to devote any annual profits it might make, to wiping off the large obligations with which its properties were burdened. It is owing to this necessity we find in the two Reports before us, that while the one has paid in three years no less than 45 per cent. in the case of the other no dividend at all save to secured preference shareholders has been paid. This contrast, were it not fully explained, would be likely to cause a doubt in the minds of the home investing public as to the soundness of the position of our present chief industry. They would probably be induced by the contrast to regard tea cultivation in Ceylon as an investment in which there might, indeed, be one or two prizes, but which was possessed of very many crushing blanks. It is, as far as may be possible to prevent such a conclusion being drawn

that we have noticed thus briefly the conditions under which the non-dividend paying Company has been worked. Our object would, however, scarcely be fulfilled unless we drew attention to the fact that, although the Eastern Produce and Estates Company has been debarred under its Articles of Association from as yet dividing any profits, it by no means follows that its career hitherto has been unprosperous. On the contrary its profits have been both large and progressive: the sum cleared last year having been £18,513 against £12,000 for the year previous.

THE BEETROOT INDUSTRY AND THE PROPOSED REDUCTION OF THE SUGAR DUTY IN THE UNITED STATES.—The reduction of the duty on sugar in the United States is likely to be a very serious matter for the beetroot industry in California. It is said that if the bill passes the machinery for a second refinery will not be put up, but will be returned, so hopeless are considered the prospects of the trade under the new conditions. What, however, California loses the West Indies will gain. The sugar trade of those islands is rapidly being diverted to the United States. Twenty years ago the bulk of the West Indian sugars came to England, but nowadays the tendency is more and more to send them to the United States.—*Stock Exchange.*

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE,

COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for June :—

A RETROSPECT.

In adopting this title it is not our intention to trace the History of Agriculture in Ceylon from the remotest times, but to look back and note what Agricultural events worthy of record have taken place during the past year in connection with our work in the School of Agriculture. The present number of the Magazine completes the first volume of the publication and the first year of its existence. It was started in July last with a double issue to meet the requirements of both English and Sinhalese-speaking cultivators, its main object being to present the scientific side of Agriculture to practical men, to encourage the improvement and development of Agriculture in directions which have hitherto been little, if at all, recognised, and to record facts of whatever nature that would be interesting to the Agriculturist. So far it is encouraging to note that our efforts have been appreciated, and subscribers in all parts of the Island have supported us. Our Magazine has come within the reach of those who, having their sole interest in Agriculture, have hitherto found no means of widening their knowledge of Agricultural matters, because no publication they had access to, gave them an opportunity of knowing more; or because they were not able to get the information they sought presented to them in a form that they could appreciate, or at a price which they could afford to pay. To the Government Agents interested in the welfare of the Agricultural classes, we owe our thanks for the help they have afforded us in introducing our Magazine to the landowners in their provinces. If but our subscribers do us the justice of paying their annual subscriptions when they fall due—and we must acknowledge that the majority have treated us handsomely in this respect—we need apprehend no financial crisis that so generally threatens such projects in Ceylon. We fear we appear

egotistic in taking up so much space in this reference to ourselves, but a note about the first Agricultural Magazine started in the island cannot be out of place in an Agricultural retrospect.

The work at the school has been carried on with much energy by all the masters, and the students have always shown a lively interest in their studies and field-work. Six students passed the final examination in December last, when the prizes were distributed by H. E. the Governor in the presence of a large assembly. Four students received first class certificates, and two received second class certificates. With the departure of Sir Arthur Gordon we lose a Ruler who always had the interests of the Agricultural classes and the improvement of Agriculture before him in the policy of his Government.

The students have taken much pains in the fitting up of the School Museum, which now shows a very fair collection of specimens illustrative of Agricultural Science. A Society for holding meetings with the object of discussing Agricultural subjects has also been formed and meets every Friday night; and it has so far progressed that a number of outsiders interested in Agriculture have expressed a desire to become members of it.

The Agricultural instructors (9 in number) in various parts of the island have been almost without exception successful in their work; and are doing much to introduce the improved method of cultivation to native Agriculturists, as well as to extend the cultivation of such crops as cotton, dhall, arrowroot, and the like, which are capable of being raised successfully in most parts of the island, and of yielding good returns. The result of their work, though by no means startling, is a steady tendency on the part of native cultivators to ameliorate their condition by the adoption of those means which are being practically worked out before their very eyes.

At the commencement of the first term of the present year 12 new students were admitted, and among them we count more than one representative of the most influential native families in the land. This is as it should be, and once we can count men of influence among our patrons, our efforts at reform should not die from lack of support.

When we notice such pregnant signs in our retrospect, who will say that the prospect is not hopeful?

CEYLON BEE CULTURE. V.

BY ABA.

In Ceylon there are four species of honey-bees viz:—

1. *Mi*—මී. *Apis Indica*.
2. *Danduwella*—දඳුවෙල. *Apis Florea*.
3. *Bambara*—බමරා. *Apis Doroata*.
4. *Kana Veyiyá*—කනවෙයිකා. *Trigona*.

The only species of bee kept by the Sinhalese is the *Mi Messa*, the common honey-bee of Ceylon. On a previous occasion I gave a brief description of the primitive mode of bee-keeping followed by the natives and the object of these articles is to point out the defects of the native method, and to induce my countrymen to follow a better system of bee-keeping.

The *Danduwella* produces very little honey and is not a profitable bee to keep. It usually attaches its solitary combs to the branch of a tree.

The *Bambara* is the most important species of bee in Ceylon. It is a large insect, prettily marked with black and yellow, and produces a large quantity of honey, as much as two or three gallons sometimes. Its peculiarly-shaped comb is attached to the branches of tall forest trees or to the ledges of almost inaccessible rocks. The bee-hunters find it very difficult to get at the combs. At the proper season several experienced hunters start on the expedition, having armed themselves with knives and ropes and materials for smoking and burning the bees. Having reached the woods where the combs are, the hunters begin work on a calm day by driving away the bees by means of smoke. The bees fly high up in the air, and before they have time enough to alight, one of the men cuts the comb and lowers it down in a basket, and quickly descends to escape being stung, for the *Bambara* when provoked is a dangerous insect, and its sting is as poisonous as that of the wasp. Directly the comb is sent down it is thrown into a fire to kill all the bees that may have remained behind. It is generally believed that the *Bambara* does not rebuild in the same place; this is very probable when we take into consideration the destruction of bee-life that takes place on the collection of the honey.

The honey of the *Bambara* though not so thick as that of the common bee is very rich in flavour and highly esteemed by the Sinhalese. This bee has never been domesticated, and it is very doubtful whether it is capable of being tamed. The late Mudaliyer Jayatileke of Kurunegala says that the *Bambara* unlike the common bee forages during twilight.

(To be continued.)

INDIGENOUS FOOD PRODUCTS : CULTIVATED AND WILD. VIII.

BY W. A. DE SILVA.

Rhamnaceae

18. *Zizyphus Jujuba*, L. Sin : Masan;

Is a tree met with in the warmer parts of the Island, generally in the south-eastern and the north-central portions. The trees attain a moderate height, and have leaves which are elliptical, green above and whitish beneath. The flowers are axillary and greenish, and the fruit is a drupe. When young the fruits are green and are of an astringent taste, but when ripe they are yellow-coloured and contain sugary matter. It is an edible fruit and is so used to a large extent. The fruit of the *Z. Jujuba* is said to possess a property of allaying pain in cases of the stinging of wasps, and the dry leaves are used in curing hiccup, asthma, &c. The seeds also are believed to possess the same properties among Native Medical Practitioners as well as the Indian Vytians. The bark of the root powdered and mixed with oil is applied to ulcers. The wood of this tree is used in India for making sandals, and the leaves are used to polish gems.

19. *Zizyphus Enoptia*, Mill. Sin : Eraminiya.

This is an arborescent creeper common in the uncultivated places, particularly the jungles of the low-country. The creeper when growing forms as it were a network. The leaves are elliptical and three veins are prominent on them. The plant is all throughout thorny, the stem is covered with thorns of different sizes, generally small and curved a little. The flowers are small and axillary, coming out along almost the whole length of the stem in well grown plants, and the fruits are borne almost at every leaf. The fruits are very small, about the size of pepper, and when raw are of a green colour. When they ripen they first assume a yellowish form and afterwards get quite black. The fruits when young are only mucilaginous, but when fully ripe they have a pleasant sub-acid sweet taste. The fruits are eaten, and are much appreciated by children. The bark of this species of *Zizyphus* is used in fermenting toddy. It also forms a good remedy in cases of dislocations, and swellings cause by violence.

THE POMEGRANATE.

(*Punica Granatum*.)

Sin : දෙලුන් (Delun); Tam : மா துளம் பளம் (Madalan-palam).

The generic name *Punica* of the genus of plants to which the well-known Pomegranate belongs is supposed to be derived from the Latin name of ancient Carthage, the fruit having been known to the ancients as the Malum Punicum. With regard to its early history among European nations, we are told that the Grecians prized it very much, and the tree was first brought to Rome from Carthage in the days of Sylla. Pliny informs us that the colour called *Punicus*, used as a dye for cloth, is obtained from the flowers, and that the flowers and

every part of the fruit were used in medicine by the Romans.

We are told that the rind of the fruit together with the bark of the tree was in use in some parts of Germany for dyeing leather of a red colour. Coming to England we find that the Pomegranate was first cultivated in that country in the year 1548 during the reign of the eighth Henry. Lord Bacon recommends wine made from the Pomegranate for complaints of the liver. He says 'let it be taken in the morning with a little sugar, and into the glass in which the wine is taken put a small piece of citron-peel, and three or four whole cloves; let this be taken from February to March.

In the East the Pomegranate has been held in the highest estimation both as a medicine and as a dessert fruit. The Persians make a kind of sherbert of the rinds with the addition of cinnamon. In Ceylon it is officinal in the Native Pharmacopia, and the expressed juice of the fruit is given in cases of fever &c. to allay thirst.

The dried rind of the fruit makes a very good ink, and in our village home many many years ago we children used to collect the rinds of the fruits we ate to be made into ink after drying with the help of a few rustynails and some vinegar according to the recipe of an old servant!

The cultivation of the Pomegranate is very easy. The usual mode of propagation is by layers, or young plants may be raised from seed. Proper pruning is necessary to get a good crop of fruit. The flowers are produced at the ends of the young branches, and the object of pruning is to remove the weak shoots and allow the strongest to flourish.

ABA.

BRINJAL CULTIVATION.

By V. KUMARAVELU.

This plant is largely grown in the tropical parts of India, and also to some extent in Ceylon. It belongs to the natural order Solanaceæ. The most important food-producing plants of this order are the Potato, Tomato, Gooseberry, and Chilli, which last is used as a condiment in all curries. The poisonous species of the above order are, Tobacco, which produces nicotine; Night shade, which gives atropine; Henbane, which produces hyoscyamine, and many others. Some of the varieties of brinjal are the egg-plant or Aubergine (*Solanum Melongena*), *Solanum-Jackquinii*, which bears prickly leaves, and brinjal proper, which bears fruits of from 12 or sometimes 15 inches long, and are largely met with in Ceylon. The fruits of the last-named kind are generally of a purple or blue colour. There are other varieties of less importance called by different names in Sinhalese and Tamil, which are hardly worthy of mention here. The different varieties may be distinguished from one another by the shape of their fruits and leaves.

The egg-plant or Aubergine derives its name from its fruits, which in colour and shape resemble an egg. It is supposed that this species of brinjal was intro-

duced from foreign countries to Ceylon, and is now cultivated largely in vegetable-garden cultivation. It has alternate, lobed leaves, and bears blue flowers. *Solanum-Jackquinii* differs from Aubergine in the smallness of its fruits, and it has also very prickly leaves.

Rich loamy soil with a thorough drainage is best suited for the cultivation of brinjal. It would be better if the soil is exclusively set apart for this purpose; but it can also be cultivated in rotation in paddy fields, if the crop is raised in such fields but once a year. The cultivation of this plant in rotation greatly improves and enriches the soil for paddy growing. Dry seasons will give a better crop than wet, especially when cultivated in paddy fields. Amongst the causes of the unproductiveness of this crop, the presence of too much of water and the application of fresh dung hold a prominent place.

The soil should be ploughed and brought to a fine tilth. Deep ploughing is necessary in this case. If there be any difficulty in ploughing, it will be better to dig with the mamoty; but digging is more costly, being about three times as dear as ploughing. After bringing the land to a proper tilth, it should be manured with well-rotted farmyard manure. Trans-planting is indispensable after the land is brought to a proper condition. For this purpose, the seed should be laid in a nursery, five or six weeks beforehand. A certain method of knowing the quality of the seed is by sowing a few of them in a small bit of prepared land, and seeing how many plants are produced by them. If the seed be good 4-5th the number will spring up. The months best suited for planting brinjal are January for the Northern and Eastern Provinces, April for the Western Province, and August for the Central Province. Care should be taken to avoid as much as possible the rainy season. The young plants should be transplanted from two to three feet apart. Farmers usually plant some green vegetables in the intervening spaces between brinjals, especially when the plants are much apart from each other. The after-culture and management of brinjal consists in occasional watering, manuring, weeding, harrowing &c., whenever required.

A pale, greenish or sometimes brown insect found on the undersurface of the brinjal leaf destroys the leaves of the young or sometimes old plants. The insect possesses a sooty appearance. Its aspect is very much like the larva of the famous tea bug. The best means of destroying this pest is to throw cold ashes over the leaves of the plant. This has been found practically to be an excellent way of destroying the pest.

Brinjal is eaten for the most part in the curried state. *Solanum-Jackquinii* is used by native doctors as a remedy for eruptions, worms, throat-aches, &c.

MINOR INDUSTRIES.

By W. ARTHUR DE SILVA.

Ceylon possesses, as is admitted on all sides, a variety of raw materials which could be made use of

in more than one industry, if only a little extra care and attention be bestowed on them. But in spite of all this natural wealth, the villagers in most districts hardly make any effort in this direction, while generally very little use is made of these materials. The industries favoured in villages are limited to the manufacture of baskets, coir-yarn, nyanda mats and the like, which however are thriving and paying well. But the number of such minor industries need and ought not to be limited to so few, and if only sufficient encouragement be given by those who have a knowledge of arts and manufactures, the result would not only be a benefit to the villagers, but an advantage to themselves; at any rate they will have the satisfaction of helping to ameliorate the condition of the poorer classes. The development of these minor industries requires not only a certain amount of technical knowledge, but it always requires that the industries should be fostered and popularised. As yet there is no body or institution whose object is the encouragement of such industries.

The aim of the following paper is to indicate the capabilities of the Island for the development of some of these minor industries, which I consider worthy of attention.

Tanning Materials.—A great demand exists at present for tanning materials both in Europe and America, as the leather trade is every day growing more extensive. Now we possess many wild and cultivated trees which yield tan to a more or less extent. The following list contains a number of trees common in Ceylon which yield tanning materials in different parts of their structure:—

	Common name.	The portion which contains tan.
	<i>Sinhalese.</i>	
<i>Acorus Calamus</i>	Wadakaha	... Leaves
<i>Acacia Catechu</i>	Ratkihiri	Heartwood
<i>Areca Catechu</i>	Puwak	... Fruit

CEYLON TIMBER TREES.

By JOHN B. DRIEBERG, L.R.C.P. & S., EDIN.

Lumu-midella (*Melia Composita*).—A quick-growing tree, timber very light, cedar like. Used for outriggers of boats, and extensively for ceilings of houses. White ants said not to attack it.

Burutu-gas (*Chloroxylon Swietenia*).—From which is obtained the well-known Satinwood. This is one of the largest and best known of Ceylon timber trees. Liable to warp and split if not well seasoned in the shade. 'Flower Satin' obtained generally from the roots &c. of this tree.

Tjurussa and Katu-keena-gas (*Xanthoxylon Rhetsa*).—A large tree producing the well-known luscious fruit. The wood is soft and much used for charcoal.

Atambagaha (*Mangifera Indica*).—The indigenous wild Mango tree from which all the cultivated specimens have sprung. One of the most gigantic of our timber trees. Seen in large numbers between Colombo and Batticaloa. The fruits are the size of a large English plum. Two or three near the Wellicadde Jail are worth going to see. Wood used for inferior purposes.

Kaju-gas (*Anacardium Occidentale*).—From its original S. American name Acajou. Naturalised in Ceylon. Yields a useful gum. Wood extensively used as the preparation of charcoal for our tea manufacturing. Yields the well-known Kaju-poolang fruit and Kaju-nuts.

Kaekuna-gaha (*Canarium Zeylanicum*).—A large tree Produces a balsamic gum resin, the fumes of which when heated is said to effectively drive away mosquitoes.

Diya-Simbala (*Æschynomene Aspere*).—The Sola or Pith hats &c. are made from a spongy substance generated in the stems of these plants when growing in water as they generally do.

Simbala (*Tamarindus Officinalis*).—The roots and heart wood of old trees superior in colour &c. to Calamander. Fruit used largely as a condiment; when ripe, with sugar is a pleasant laxative.

Ehala (*Cassia Fistula*).—Wood close-grained but small and curved. Used for tom-toms. All parts used in medicine.

Kumbuk (*Terminalia Glabra*).—A very majestic tree. The best specimens can be seen from Beligam northward to Jaffna, and from thence to Batticaloa. The natives believe that water will always be found by digging near the Kumbuk tree. A writer in the *Ceylon Examiner* some time ago gave an account of one of these trees which sprung a fountain out of its trunk, out of which a number of travellers slaked their thirst! One of the most majestic specimens of this giant of the Ceylon forest can still be seen near the high road beyond Whist Bungalow (the late Sir Richard Morgan's residence Modara). This tree has been described by Sir Emerson Tennent as well worth a visit. This tree resists the most powerful storms. It is said never to lose its leaves. The Kumbuk tree at Modara measures at the base close on 30 feet in circumference.

Dawatagaha (*Carallia Integerrima*).—A common shady tree. Timber is strong and ornamental.

Marithondi (*Lawsonia Alba*).—The country Mignonette. Tree small but wood tough; a good fence plant. Flowers peculiarly fragrant. The leaves well crushed and moistened with a little water and placed over the nails will stain them a bright red in a few minutes, and are used largely by the Tamil women for this purpose.

Gedi Kilala (*Sonneratia Acida*).—The Ceylon cork tree, found in swamps. Wood light and white and used for models of boats. It is said to be a better substitute for coal than any other kind of wood. The curious white spongy spindle-like columns, which are thrown up from the roots of this tree are used as corks, for models, and lining of the inside of insect cases.

Uncaria Gambier.—Is quite a common plant near Colombo and Galle and Deltota and Dumbara. The extract from it is the Gambier, Gamber or Terra Japonica of commerce, and found to be an excellent preservative of timber, especially against the attack of the Toredos; thus discovered by the wreck of a ship a large portion of the cargo of which was composed of Gambier. After being immersed for a considerable time in salt water, the bags in which it was packed, and the timber near it were found to be in perfect preservation from the effects of the dissolved Gambier. Mr. Wm. Ferguson was the first in Ceylon to make this from the indigenous plant. For the preservation of timber, especially for railway purposes, they ought to become an important article of local use as well as an export from Ceylon.

Maha-ratambala (*Ixora Parviflora*).—A small-sized tree employed for beams and posts, but is chiefly used for chules, as it burns readily and is thus used by travellers at night, in India, where it is known as the torch tree.

Palu-gaha (*Mimusops Indica*).—An abundant tree towards the north of the island. One of the best timbers and best known in the island under its native names, and very much confounded with real iron wood (*Musaa ferrea*). Timber extremely hard, strong and durable, used for oil-presses, bridges, house building, &c., and next in value perhaps to Hal-milille (*Berrya Ammonilla*).

Tel-mee-gaha (*Bassia Longifolia*).—A most useful tree. Large quantities of oil made from its fruits by the natives. Timber used for keels of dhonies, bridges, and house building. Very much cultivated.

Maha-timbiri (*Diospyros Embryopteris*).—Wood used for building, but of indifferent quality. Every part of the tree used medicinally or in the arts. Juice of the fruit very glutinous and charged with Tannic Acid, and used by natives for paying the seams of fishing boats and for preserving their lines and nets.

NOTES FROM EXPERIMENTAL STATIONS.

Mr. Edwin Hoole of the School of Industry, Haputale, writes about a grape vine which was grown experimentally, being sent from the Hakgala Gardens by the Superintendent, Mr. Nock. "It was about a foot

high when received, and was planted against a rock well-exposed to the morning sun. The plant was set in a pit about 3 feet square and filled with a mixture of soil and half-rotted dung. The site being on sloping ground, a drain was cut above the pit to carry away rain water and thus prevent wash. A young calf happening to die a few weeks after, its carcase was buried close to the pit on the upper side. With such treatment, one would naturally expect the plant to thrive well; and so it did for some time, making a good start and growing luxuriantly for a couple of months. Then something evidently went wrong with the vine for it lost its former luxuriance and became stunted. After much speculation as to the cause of the mischief, the ground was dug deep round the plant, and it was then found that the roots of a rather old but stunted fig-tree standing some ten yards distant from the vine, had spread round the young plant like a network and were robbing it of its manure. When the pit was first cut no traces of the fig-tree roots were found anywhere near it, and it was not expected they would reach the pit as the distance and relative position of the two trees seemed against this. It was in fact intended that the fig-tree should be a shelter to the young vine from violent winds. However, the intruding roots of the fig were promptly removed, and a deep trench has been cut between the fig-tree and the grape-vine. The latter has now regained its former vigour and luxuriance and continues to grow rapidly. This bit of experience well illustrates the tendency of roots, amounting almost to an instinct, to go in search of food, while it at the same time shows us how plant food is often mis-appropriated, and the necessity there is for guarding against such loss of food caused by weeds growing in our cultivated areas."

Mr. Lawrence Perera, Agricultural Instructor at Kuliapitiya, writes:—"A few beds of potatoes were planted by me in September last, and yielded nearly sixteen-fold. The beds were situated in a shady place, and dung and ashes were supplied as manure. The tubers produced were however of no size. I have again planted 3 lb. of potatoes. My onions produced excellent bulbs and a crop of nearly eighteen-fold was got. Mr. Bailev, the Government Agent of the North Western Province, inspected my experimental garden and distributed prizes to the students who showed aptitude for agricultural work. The first prize was won by Kiri Banda of Galapitiyawa. The American Cotton growing here is at present fruiting, the Egyptian variety is also thriving well. Cotton, arrowroot, and dhal were planted in March, while horse-gram, groundnuts, two varieties of onion, mustard, chilli and beans have also been put down.

OCCASIONAL NOTES.

A visit to the Industrial Home at Wellawatte impresses one with the enormous amount of good that can be effected by the establishment of more of these philanthropic institutions. There are certain classes

in Ceylon that from various causes seem utterly unable to help themselves, but it would be hardly fair to say that this is purely the fault of the individuals of these classes. To leave them to their fate in the struggle for existence would be callousness: to throw money to them indiscriminately, and so satisfy our consciences that we are charitable, is productive of more harm than good; for while it encourages an idle spirit in them, it robs them of all self-respect and every spark of independence. In an institution like the Wellawatta Industrial Home the policy adopted is to help them—not to do nothing but—to help themselves. Here the boys are led into the way of working and earning a honest livelihood, and, what is most admirable, their young minds are being moulded by those in charge of them in a fashion that must eventually stamp them as a new class of intelligent, willing and upright labourers that, speaking without prejudice, we are sadly in need of. To the Wesleyan Missionaries is due the credit of this good work, and especially to the Rev. Mr. Bestall, who we hear is hoping to be able to establish a sister institution for girls.

The "Weather Plant," which has attracted so much attention in Botanical circles, and to which No. 37 of the *Kew Bulletin* is entirely devoted, is of quite common growth in Ceylon—its Sinhalese name being *Olanda*. It is a creeping plant belonging to the order Leguminosæ, and the seeds of the legume commonly known as *Coondoomannie* (which is the Tamil name of the creeper), are scarlet, black and white. The commonest however are of a bright scarlet colour with a jet black spot at the top. These latter are used by jewellers as weights, each weighing almost uniformly one grain, and also as beads for necklets. The seeds are said to be innocuous if swallowed whole, but dangerous in a powdered state: yet, on the contrary, it is stated that they are used as an article of food in Egypt. They are occasionally employed for external application in ophthalmia, and reduced to a fine powder, are used by goldsmiths to increase adhesion in the more delicate parts of fine ornaments. The root is employed as a substitute for liquorice, hence its name "wild liquorice." The leaves mixed with honey are applied to swellings, and pulverised and chewed with sugar are used to mitigate coughs. It is also stated by Drury in his book (1858) that the leaves were reported to be used instead of tea in Jamaica. It was Professor Nowach of Vienna who first observed the peculiar movements in the leaflets, and carried on his observations for over 4 years, coming to the conclusion after some 34,000 experiments, that the plant possessed the marvellous property of forecasting the weather, the direction of wind, electrical disturbances and earthquake shocks!

Mr. J. A. Kodipilly furnishes us with the following interesting and at the same time startling extract from the *Scientific American* of February 22nd:—

"At the October meeting of the Vienna Academy of Sciences, Theodor Gross, of the Technical High School of Berlin, presented a paper of a very startling character, in which the author endeavoured to make it plausible that sulphur is not, as now considered, an element, but a compound of carbon with some other as yet undetermined elementary substances. We quote from the *Chemiker Zeitung* of Coethen:— Heating a thin layer of precipitated sulphur in a porcelain capsule and allowing the ignited mass to slowly burn without further application of heat, there remained as residue a black pellicle, which after heating in the presence of air, was converted into a light brown powder amounting to 0.2 per cent of the original weight of the sulphur. Of this, one part was gradually introduced into forty parts of fused potassium hydrate contained in a silver capsule, and after adding five parts of potassium chlorate, the application of heat was continued until the mass ceased to foam. After treatment with water this fuse left a flocculent precipitate; the liquid, after filtration, disengaging with hydrochloric acid a comparatively large volume of carbon dioxide. The precipitate was readily dissolved by warm dilute hydrochloric acid containing a little HNO_3 barring a minute argentic residue. Added to this solution, potassa or NH_3 produced flocculent precipitates insoluble in excess even after heating, but readily soluble in acids. After nearly neutralizing the excess of acid with potassa, the addition of hydrogen sulphide produced a light brown, very flocculent precipitate, which was thoroughly washed with hot water. This precipitate, according to careful investigation, contains a new body. Of all the known elements, only traces of copper might be present. This residue, when strongly heated in open porcelain crucible, fused together to small granules, having the appearance of selenium, whose weight amounted to about 2.5 per cent of the light brown powder obtained by incinerating the sulphur. Two and seven-tenths, e.g. of this powder strongly heated in a current of hydrogen lost 3 mg. The remainder dissolved in hot concentrated HNO_3 gave a ppt. with a large excess of NH_3 , which being carefully washed, was again dissolved in dilute HNO_3 . In this solution hydrogen sulphide again produced a light brown ppt. and potassium hydrate or NH_3 a ppt. insoluble in excess. The author claims that this body so obtained cannot possibly be considered a contamination of the precipitated sulphur employed, for his results were always the same with samples procured from various sources, while with roll sulphur he had negative results. He considers the body a product of decomposition of the sulphur used, being related to the allotropic condition of the same in the precipitated form. For reasons to be made public at some other time, he considers sulphur a compound of carbon with several other bodies now looked upon as elements. He also believes the body above described to be such a combination."

GENERAL ITEMS.

The *Kew Bulletin* for January last contains an account of the "Weather Plants" (*Abrus Precatorius* Linn.), for which Professor Nowach of Vienna claimed the property of foretelling changes of weather and earthquake shocks. The plant has been under observation at Kew, and an exhaustive report on it is furnished by Dr. Oliver. Observations and experiments do not, however, tend to prove that the "weather plant" is a *reliable* indicator of climatic changes or of earthquakes.

A unique specimen has been lately added to the School Museum collection, viz., a double egg or one egg inside the other. The eggs are perfect each with its own shell, the two shells being connected at their bases. It is difficult to speculate what would have been the result if this *usus nature* had been hatched!

An enquiry made by Sir Joseph Hooker has elicited the information that Piuri (Purree) or "Indian Yellow" used in painting walls, doors, railings and sometimes for dyeing cloth, is made from the urine of cows fed with mango leaves.

The cost of destroying rabbits in New South Wales is enormous, the Government having expended nearly £1,000,000, and the pastoral lessees about £250,000. A new Rabbit Act, making destruction of the pest compulsory, is proposed. Pastoral holdings are to be fenced with rabbit-proof wire fencing. Lessees are to be aided by Government in enclosing their holdings. The Minister of Lands estimates that it would cost £3,000,000 to enclose the leasehold areas in the Western and Central divisions of the Colony with rabbit-proof fencing.

It seems that of late several cases in which damages have been claimed for injuries sustained from barbed-wire fences have cropped up in different parts of England, and in these cases it has been held that such wire is not proper fencing to have where the public frequent. "Barbed-wire," says the *North British Agriculturist*, "is not only dangerous in tearing people's clothes and pricking them, so that blood-poisoning sets in, but it deteriorates the value of the hides of sheep. This is a fact that many tanners are now becoming acquainted with. Considering the amount of harm that barbed-wire does, compared with the imaginary benefits in the shape of being a deterrent to man, it is a wonder that it should be used at all." We commend these remarks to the Kandy Municipality or whoever is responsible for the putting up of the barbed-wire fence along the Kandy Bund, where the object it is intended to serve is difficult to see.

The following quotation from the *Indian Agriculturist* of the 25th January will prove interesting to those who so keenly discussed the question in the local papers, as to whether silica was necessary to produce stiffness

in the leaves and stems of graminaceous plants and trees:—"The generally accepted theory that the strength of straw is dependent on the amount of silica it contains, is now proved to be wrong. Dr. Gilbert, a practical chemist, found from analyses of ten samples of wheat and twelve of barley—all of different seasons or different manuring—that the proportion of silica is as a rule not higher in the straw of the better-grown and better-ripened crops. In both the wheat and the barley the percentage of silica in the straw is under all conditions of manuring much the lower in the better seasons. With the wheat under such conditions of manuring, and with the barley under most conditions, it is considerably lower in the better seasons. Dr. Gilbert concludes that the high percentage of silica means a relatively low proportion of organic substance produced, and the strength of straw depends on the favourable development of the woody substance, and the more this is attained the more will the accumulated silica be, so to speak, diluted."

This opinion of Dr. Gilbert, the co-worker of Dr. Lawes, comes with great force. Prof. King, lecturer on Agricultural Chemistry, and analyst to the City of Edinburgh, in discussing the question of whether silica was an indispensable element of food to some plants used to say that the probabilities were it was not indispensable; and that the want of silica in a soil was not the cause of "lodging," which was caused by the want of some other ingredient. Silica, says Warrington, was long supposed to be an essential constituent of wheat, barley, and other similar plants, and to be the ingredient on which the stiffness of their straw chiefly depended. It has been shown, however, that maize and oats may be successfully grown without any supply of silica, and with no perceptible difference as to the stiffness of the stem. The grass growing on peat-bogs also contains scarcely any silica, though silica is abundant in ordinary hay.

The Journal of the Royal Agricultural Society of England to hand is full of interesting and valuable information on a variety of subjects. The journal has been hitherto published annually, but the present issue, the first part of Volume I. of the third series is to be continued quarterly.

The death is reported of Mr. Herbert Little, so well-known to the Agricultural world as a high authority on farming in general and cattle in particular. Mr. Little was Honorary Professor of Agriculture at Cirencester, and used to deliver a few lectures on general agricultural subjects at the college each term. He was always known as a most genial and versatile man, and his loss will be not a little felt by those who knew him and the students who used to listen to his lectures.

Professor Wallace of the Edinburgh University writes of his intention to spend May and June in the American States. The Professor's brother, Mr. John Wallace of Holmhill, Thornhill has been appointed lecturer on agriculture at Heriot-the-Watt Technical College,

 SCHOOL NEWS.

The half-yearly examinations commenced on the 26th May and closed on the 30th.

The summer vacation extends over the whole of June: the school re-opening on the 1st of July.

The students had the privilege of visiting the Cotton Mills at Wellawatte on Saturday the 17th, and were shown through the entire establishment—the various operations being explained and illustrated to them in succession from the ginning of the cotton

to the weaving, folding, and packing of the manufactured articles.

Through the courtesy of the Principal of the Medical College we have been able to avail ourselves of the use of the geological specimens, of which there is a very fair collection in the Medical College Museum, for identification of minerals by the students.

At the request of a gentleman interested in coconuts, one of the students of the School of Agriculture gave his willing services in starting the ploughing of some coconut land at Maradana with the improved ("Cingalee") plough. The work progressed very satisfactorily.

ROYAL BOTANIC GARDENS.

EXTRACTS FROM THE REPORT OF THE DIRECTOR FOR 1889.

1.—Pérádeniya Gardens.

THE cumulative work of the past ten years has at length resulted in the whole extent of these grounds being in fairly satisfactory order and well in hand, all that is now necessary being to keep them up at the improved standard they have reached. For this purpose our labour force is sufficient, and the increase made during the past year to the vote for Garden requisites has raised that also to an amount more adequate to meet the various demands of a large botanical establishment.

Lawns.—The fine stretches of turf have had much attention devoted to them during the year, and are very greatly improved. A large staff of boys has been constantly at work digging out the *Elephantopus* and other disfiguring weeds, levelling, removing anthills, stones, &c., working the meadow-mower and smaller machine, and sweeping up leaves. The large meadow-mower was thoroughly repaired in the early part of the year. The extraordinary rains of April brought on the annual attack of beetle-grubs earlier than usual, and by June the lawns were almost bare, but as usual they quickly recovered themselves.

Though not connected with the Botanic Gardens, this seems also the right place to put on record the successful establishment at Colombo of the great Brazilian water-lily, *Victoria regia*. Two plants of this, from the Agri-Horticultural Society's Garden at Madras, were brought by the Honorary Secretary, Mr. Thurston, to Colombo in October, and having been planted in a new tank in the Fort Public Gardens produced flowers in January, 1890.

Labelling.—The majority of the trees and shrubs of interest are now provided with clear and conspicuous labels, this work having been vigorously carried on during the year, two or three men being kept constantly employed. The interest and usefulness of the Garden to visitors have been very greatly increased by the information thus given. The labels now used are made of brick, and are beyond the attacks of white ants, and very permanent. This is the cheapest material that can be obtained, and the only defect is a liability to break across near the ground, owing to imperfect baking. The lettering is in white paint on a black ground, and this is the principal cost. I am also experimenting with another label, in which printed tickets can be employed (thus much reducing cost); these are made of cement, in which a piece of glass is inserted over the name, and if these are found to be watertight they will probably be the best and cheapest form.

Large labels bearing the names of the Natural Families have been set up in their respective places in the Herbaceous Ground.

Visitors.—No less than 1,534 persons (not resident in Ceylon) signed their names in the visitors' book, a considerable increase over last year. The opening of the new station at Pérádeniya, which took place on December 1, has rendered it easy to visit the Gardens by train, the station being no more than about a quarter of a mile away.

Weather.—Though the rainfall for 1889 was about the average in quantity, its distribution was very unusual. As a rule, our two wettest months are October and June, but their places were

occupied in the past year by April and July, months with usually but a moderate fall. The rains of the north-east monsoon, in the three last months of the year, were also remarkably slight in amount, only 18.42 in., against an average of 31.10 in. for the previous six years, and the deficiency here was made up (so far as the whole yearly amount is concerned) by the extraordinary fall in April—nearly double its average for the previous five years—and in July. The unusual distribution has considerably affected the averages of past years.

This comparative failure of the north-east monsoon has not injuriously affected the vegetation of the Gardens in any way, but the premature and excessive fall in April stimulated the giant bamboos to send up their culms a month or more before the usual time; they grew, too, with great rapidity—one which Mr. Clark measured lengthening at the rate of 13½ in. in twenty-four hours. The fine mass of this species, which I mentioned in my last report as having suffered from the flood of 1888, appears to be still further weakened by this excessive growth, and one side of it has died. The whole clump will have to be removed.

2.—*Hakgala Garden.*

Many improvements have been carried out here during the year, details of which are given in the Superintendent's report printed below. The most important are the continuation of the retaining wall along the high road, the remaking and metalling of the old carriage drive, the repairs to the Conservatory, and the clearing and transformation of an abandoned tea and coffee plot below the nurseries. So many new roads and paths and other alterations have been made in the Gardens during the last eight years, that it is now very desirable that they should be re-surveyed, and an accurate plan made.

I again wish to urge the necessity of an examination and report by an expert on the best mode and probable cost of a constant supply of water to the Garden. Its want was not experienced to any serious extent during the past year owing to the even distribution of the rainfall, but severe droughts may at any time occur again.

The number of species in cultivation in this Garden is now over 2,500, and is constantly increasing; it is in contemplation shortly to affix labels to the more interesting and attractive plants.

During my absence in Europe on leave Mr. Nock acted as Director of my Department, and carried out his duties in a very satisfactory manner.

Hares and Porcupines.—These animals have been very troublesome during the year. The former do great damage to the Herbaceous Garden and Nursery, as well as in the little experimental plots of grass. The porcupines destroy such plants as iris, lilies, cannas, dahlias, and others with roots of a bulbous or succulent nature. We have tried to catch them with snares and traps, but have, as yet, failed.

Visitors.—The number of visitors during the year was 1,185, being an increase of 69 over that of last year. The largest number in any month was 194, in January, and the smallest 31, in June.

Weather.—The weather was remarkable for an excessive rainfall during the first nine months of the year, for the late and very light north-east monsoon, and for the strength and continuance of the wind of the south-west monsoon till quite late in the year. It did not really settle down and come steady from the north-east quarter till the end of November. During the south-west monsoon the wind continued at a higher rate of speed for a much longer period than has yet been recorded from this station, and in consequence much more damage was done to the trees and plants than usual. I may state that the anemometer shows the true direction of the wind that passes over this Garden during the south-west monsoon to be N.N.W., and that during the north-east monsoon is E.S.E.

The total rainfall for the year was 88.34 inches, which fell on one hundred and eighty days. This is a little less than last year, but still about 1 inch higher than the average for the previous five years, which was 87.36 inches.

The average mean temperature of the air for the last six years is 63.1.

The highest temperature in the sun's rays during the year was 154 on March 10, and the lowest on grass was 37 on December 31.

The mean amount of cloud for the year was 6.8, the cloudiest month being November, with a mean of 8.2, and the brightest month was, again, February, with a mean of 3.9.

3.—*Henaratgoda Garden.*

The Muhandiram in charge reports that the very wet season from April to September caused much wash and necessitated a good deal of work in renewing the paths. No record of rainfall is kept here except of the days on which it falls, which were 163 in the past year.

The Garden is in excellent order, and its contents generally in a flourishing state. A few improvements have been made during the year. New gates have been put up at the entrance, the plant house has been improved by the erection of brick stages and a roof of coir matting, and the Conductor's house painted and his office enlarged; this building requires tiling. About half an acre of the remaining jungle has been cleared and a plantation of black pepper, grown on *Erythrina* sticks, formed. Two hundred brick labels from Peradeniya have been painted with the names of some of the most interesting trees and set up in their places.

Very few persons now visit this charming little tropical Garden; there were but twenty-nine in the course of the year. As I have remarked before, this is due to the fact that the quick trains

no longer stop at Henaratgoda station, and that the nearest resthouse is at Mirisweti, three miles from the Garden. By leaving Colombo, however, by the slow train at 6 A.M., it is possible to spend some three hours at the Garden and get back to Colombo before midday.

4.—*Anurádhapura Garden.*

We have had much difficulty this year in obtaining water for the Garden, the supply from Tissa tank being only occasionally available for us. Moreover, the small pond in the Garden is so nearly on a level with the point in the *éla* from which our open channel is supplied, that, even when allowed to enter, water will scarcely flow. After consultation with the Public Works Officer, it has now been decided to deepen the pond, and to supply it from a point in the *éla* much closer to it, by a short sluice through the bank. It is hoped that this alteration—the cost of which can be met from the small Provincial vote annually placed at my disposal—will be effected early in the year, and that thus, being able to fill the pond periodically, we shall be able to tide over times of scarcity. The rainfall for 1889, however, 49·76 in., though rather below the average, was fairly well distributed, falling on no less than eighty-eight days. As elsewhere in the Island, April was an extraordinarily wet month, 10·73 in., falling on fifteen days, being registered.

A portion of the Garden which was very rough has been levelled, the Arachchi's bungalow thatched and repaired, and cooly lines partly built. No prison labour has been available for work in the Garden during the year, owing to all being engaged on the clearing and excavation of the ruins. I was able to purchase 200 loads of manure for the Garden this year, which was much needed.

5.—*Badulla Garden.*

Progress here is but slow; want of labour, a very irregular supply of water, and the trespass of cattle are some of our principal hindrances. With regard to the first, it has been a subject of some surprise and disappointment to me that my frequent requests for the use of some of the large number of prisoners employed on public works in Badulla have been met to the extent of only ten men for five days during the whole of the past year. I hope, however, that now certain large improvements in the town have been completed, more assistance in this way will be provided for the Garden. The conductor would be enabled to make considerably more progress if a small number of prisoners were regularly told off for work here, and the practice steadily continued for some time.

As regards the water supply, it is expected that this will be provided for by means of a channel which is to be carried across the Garden for the supply of an artificial lake in the centre of the adjoining racecourse. In connection with this channel, it is intended to make a tank in the Garden, and I have the assurance that for this work prisoners will be allowed.

A fairly good supply of manure is regularly received from the town. By its use many of the trees and shrubs are making good growth and beginning to give some shade to this very exposed piece of land.

8.—*Notes on Economic Plants and Products.*

Tea.—It has been my custom in these annual reports to place on record the exports of the leading plantation products of the Colony, and make some comment upon them. The story, however, from year to year is now of much the same character, the tea enterprise having so greatly overshadowed all others and engrossed so much attention, that there is less and less to report on other products.

The export for the commercial year ending September, 1889, reached over 32½ million pounds (32,516,682 lb.), nearly 12 million lb. more than in the previous twelve months. For the calendar year 1889 it amounted to 33,383,035 lb. The Australian Colonies took of this somewhat over 1¼ million pound (1,134,156 lb.), a considerable increase over the year before, but still a very small proportion of the 24 million pounds annually consumed in those Colonies.

The price of our tea in the London market has been subject to remarkable fluctuations during the year, being very low in the middle, but more than recovering towards the end; and the average for the whole year may be put at somewhat over 11*d.* per lb., which is very little less than that of the year before. Bearing in mind the greatly increased quantity, this must be considered a decidedly satisfactory position.

Encouraging, too, is the general absence at present of any serious drawbacks to cultivation in the way of insect or fungus enemies. Green bug is troublesome in a few places, and at least one attack of *Helopeltis* ("Mosquito Blight") has been recorded, but these are of little account. It is, however, most earnestly to be hoped that this present general immunity from any serious pests will not blind planters to the necessity of providing against future possibilities by paying attention to other cultivations.

Cinchona.—The export for Ceylon for the commercial year has been 10,498,487 lb., a further fall of over a million pounds in the gradual lessening which has been going on since 1886. The

diminution is further exhibited if we take the figures for the calendar year 1889, which are only 9,179,280 lb., and the process must now continue at a rapidly increasing progression. As a consequence, the price of bark may be confidently expected to rise, though it must be remembered that our place as dominating the market is being taken by Java. The question, however, arises whether a revival of cultivation here should be recommended, and it is well worthy of consideration. Speaking generally, I consider it has been sufficiently proved by experience that neither the soil nor the climate of Ceylon are well suited for cinchona trees, which have shown themselves here to be, as a rule, short-lived and unhealthy. I refer especially to the wet and windy localities so frequent in the planting districts; the mortality here is indeed so great among young trees as to render it almost impossible to cultivate cinchona with success. But in the drier districts the case is different, and in places where *C. officinalis* and *C. robusta* hybrid do well the cultivation is likely to again prove very profitable. But with the large consignments of bark of high quality from Java to compete with, it will be more than ever useless to grow inferior varieties.

Coffee.—An export of 86,440 cwt. for the commercial year—84,749 for the year 1889, a decrease of over 50,000 cwt.—shows coffee to have at length come down to the position of a quite secondary product. Nor—in spite of the encouragement of high prices—are there any signs of a general attempt at a revival of this cultivation. Reports, however, of the great improvement of coffee under shade in Coorg and Mysore have led to the planting up of some estates with trees, especially with the native *Ficus glomerata*, which is considered in India to be peculiarly suitable. The effects of shade on the appearance of coffee are undoubtedly striking, and in very dry climates (as the districts of India mentioned) particularly so; diseased and exhausted bushes are doubtless kept living and retain their leaves longer when shaded, but the quantity of blossom and crop is, I should suppose, not likely to be increased. Moreover, it should be remembered that the shade-trees themselves are an additional burden on the land (an important matter on a poor soil). On the other hand, they undoubtedly afford some protection against continual and excessive infections by the spores of *Hemileia*; and their general absence in Ceylon in the past doubtless helped on the very rapid spread of leaf-disease through the Island.

Cacao.—There has been a considerable increase in the export of this for the commercial year 1888–89, 14,461 cwt.; and that for the year 1889, 17,164 cwt., is the largest yet recorded. It is much to be regretted that so small an area of the country appears suited to this cultivation. Even in suitable localities cacao still suffers somewhat from the attacks of *Helopeltis*; and larger enemies that have to be kept down are squirrels and wild cats.

Caoutchouc Trees.—With reference to the remarks I offered in my last report as to the great desirability of Government taking up the cultivation of *Hevea* (Para rubber) on a large scale, I have now the satisfaction of being able to record that the Forest Department has made a commencement by the selection of land near Námápana, in Sabaragamuwa, a portion of which is to be cleared and planted during the ensuing season. This decision was not come to till too late in the year to enable the seed of 1889 to be used for the purpose. We had a large crop at Henaratgoda, and a smaller one at Pérádeniya. As I have often had occasion to point out, these seeds quickly lose their vitality and have to be sown immediately. About 8,000 were sold, a considerable number sent properly packed to Queensland, and the remainder sown at Henaratgoda, where there are now several thousand seedlings, which, when “stumped,” can be rendered available for planting out.

I have supplied the Forest Department with such information as our experience of this tree at Henaratgoda has afforded us. It may be useful, as showing the rate of growth, to bring together the records taken at the end of each year of one tree at Henaratgoda for the past ten years. The tree was four years old in 1880; the circumference is taken at 3 ft. from the ground.

	ft.	in.		ft.	in.				
1880	1	4	1885	3	7
1881	1	9	1886	4	1
1882	2	1½	1887	4	5½
1883	2	6	1888	5	0
1884	3	0	1889	5	5

The Panama rubber trees (*Castilloa*) do not now grow rapidly; the best tree at Henaratgoda has increased during the year half an inch only, being now 3 ft. 5 in. in circumference. At Pérádeniya the trees of this species are not looking healthy or thriving well.

In March last the conductor at Henaratgoda experimented on the rapidity of the flow of rubber from a Para, a Castilloa, and a Ceara tree respectively, and reports that to obtain 4 oz. rubber it took, from a Para tree 3½ hours, from a Castilloa 2 hours, and from a Ceara 5 hours.

To illustrate the importance of the caoutchouc trade, I may quote some figures of the imports from Brazil into the United Kingdom. In 1887 no less than 113,955 cwt. were imported, valued at £1,655,115, or about £14 per cwt.; the greater part of this was Para rubber, the price of which during the past three years has varied between 2s. and 3s. 6d. per lb. This enormous quantity is wholly

obtained from wild trees, and additions to the sources of supply are urgently needed ; indeed, there is every probability that in the long run, as with cinchona so with caoutchouc, it is upon systematic plantations in the Old World that we shall have to depend for our supply.*

Guttapercha.—The increase in these slow-growing trees is but slight. *Payena Leerii* is 23 ft. high and 10 in. in circumference, and *Dichopsis pustulata* 14 ft. 9 in. high, with a circumference of stem of 9 in.

Cotton.—The mills of the Ceylon Spinning and Weaving Company at Colombo being now in working order, the company is prepared to purchase at certain rates any quantity of Ceylon-grown cotton ; and a considerable quantity of the Tinnevely sort and smaller quantities of Egyptian and New Orleans has come in from the Jaffna, Batticaloa, and Anurádhapura districts.

In continuation of previous consignments (see my last report), Mr. Mitchell sent, in January, seed of the Bourbon variety. This was tried at Henaratgoda, Badulla, and Anurádhapura, and in the latter Garden afforded a small but fairly good crop of pods. At Badulla it suffered much from red bugs, and at Henaratgoda it failed completely.

A very successful experiment with Sea Island cotton on an estate in the Dumbara district requires some notice, as showing what may be done by careful cultivation in a favourable season. A very fine crop is now (February, 1890) being harvested off 90 acres sown at the end of August in good soil, after experiencing an eminently favourable north-east monsoon.

By the kindness of the proprietors I have been provided with the record of rainfall for the last three months of the past year, the critical time when the pods were ripening, and of the two previous years ; and as the result so strongly confirms the remarks made in my last report as to influence of dry weather on this cultivation, the record is here given:—

		1887.		1888.		1889.
		Inches.		Inches.		Inches.
October	...	8·82	...	10·55	...	7·47
November	...	11·51	...	6·31	...	4·68
December	...	17·21	...	9·64	...	3·03
		<hr/>		<hr/>		<hr/>
Total ...		37·54		26·50		15·18

The contrast of the past season, as compared with 1887 and 1888, is very marked, especially in December, and the failure of the rains of the north-east monsoon, however injurious to some cultivation, proved most beneficial to the cotton crop. The only insect enemy which proved serious in this locality was *Helopeltis*, which almost destroyed a patch of a few acres ; but its ravages were stopped completely by a systematic catching by hand.

Tobacco.—A large quantity of tobacco, chiefly of the Sumatra sort, has been grown and cured in the Mátalé and Dumbara districts, and at the present time (February, 1890) as much as 62 tons of cured leaf is being sorted and stacked on one estate in the latter district, where most of the curing is carried on. It remains to be seen how Ceylon high-class tobacco will fare in the home market.

*Cubeb*s.—My efforts to obtain this plant for the Gardens have been continued. On June 5, we received from our correspondent at Soerabaya, Java, a Wardian case containing twelve plants and six cuttings, with the assurance that the greatest care had been taken to insure the acquisition of the right plant. The cuttings were dead, but nine of the plants were in good order, and these were at once planted out, and are doing well both at Pérádeniya and Henaratgoda. None have yet flowered, but from the foliage alone I fear that again we have failed to obtain the true *P. Cubeba*. I still, however, hope to get from Java ripe seed (as to which there could scarcely be any doubt) sown in a Wardian case and allowed to germinate before leaving.

Gambier.—This product has been suggested as a desirable cultivation for the natives in the wet districts of the south of Ceylon, and an application from the Government Agent of Ratnapura for a large supply of seed has been forwarded to the Singapore Government. I made a few remarks on the plant affording this substance in my Report for 1887 (p. 14), and on the difficulty I had found in getting either plants or seeds here alive. In August last we again received a small supply of

* The only plantation of *Hevea* in the East at present is that under the Indian Forest Department at Mergui, Lower Burma. According to the last Report (1888-89) there are here 49 large trees—probably the survivors of the 500 sent from Ceylon in 1878—6,358 put out in 1887 and 1888, and 15,607 in nurseries.

seed, but none germinated, and in November two plants arrived in a Wardian case, but soon died. I am now informed by Mr. Ridley, Superintendent of the Singapore Botanic Gardens, that these seeds do not retain their vitality after gathering for more than twenty-four hours. But the plant grows like a weed at Singapore, and if once successfully introduced here would probably flourish equally well.

Sarsaparilla.—The “Jamaica Sarsaparilla” of commerce is the produce of *Smilax officinalis*, and comes chiefly from the Cordillera of Chiriqui in the Isthmus of Panama. It derived its name “Jamaica” from being formerly brought from Central America to that island, whence it was exported to Europe. Of this plant next to nothing is known, but a *Smilax* has been cultivated in Jamaica itself for many years, and affords a sarsaparilla which is exported to a small extent. A local nurseryman having recently forwarded a sample grown in Ceylon from plants of this kind imported from Jamaica, attention has been again called to the plant, of which several specimens from Kew are in cultivation at Pérádeniya. I gave a woodcut illustration of the base of the stem and roots of this *Smilax* in “Medicinal Plants” (sub t. 289), in an account of *S. officinalis*, to which species the late D. Hanbury considered it to belong: but as I there pointed out, the specimens do not well agree with De Candolle’s description of the type-specimens of that species. Quite recently also Sir J. Hooker has expressed his opinion (Bot. Mag., sub t. 7054) that the cultivated Jamaica sarsaparilla and *S. officinalis* will prove, when their flowers are known, to be different species.

Disease in Cocoanut Leaves.—Some alarm was caused in the early part of the year on a cocoanut estate at Véyangoda by an affection of the leaves of this palm. The disease was seen to commence as small yellow roundish spots, which gradually die in the centre, and by spreading and coalescing finally result in the death of considerable portions of the leaf. A parasitic fungus at once suggested itself as the cause, but a careful microscopical examination has not revealed to me the presence of any species likely to cause the damage. Mr. M. C. Potter, of Cambridge, however, who investigated some material which he took home with him from Ceylon, informs me that he finds a fungus in the patches allied to *Helminthosporium*, which he thinks may do some damage. This I did not detect in the specimens examined by me, and I have arrived at the conclusion, from an inspection of the trees and from the history and local character of the affection, that the malady is due to some cause affecting the general nutrition of the trees attacked. The disease does not show any decided tendency to spread even in the neighbourhood of the worst cases.

Oranges from Queensland.—The loss of a consignment of grafted oranges from the Queensland Acclimatization Society in 1886 was recorded in my report for that year (p. 10); and I am now glad to report the arrival of a second assortment in September in excellent order, from the same source. There are twenty-four selected named varieties, and a plantation has been formed at Pérádeniya, where they are doing well.

Kei Apple (Aberia caffra).—Bushes of this at Hakgala of some age, but of the origin of which we have no record, fruited during the year. This large spiny shrub is a native of Natal and Kaffraria, and grows well in South Europe and other warm temperate regions; in Natal it is much used for fences. The fruit has a very agreeable acid flavour, and is well adapted for preserves. The plant is a near ally of our native “Kétembilla” (*Aberia Gardneri*), the smaller fruit of which is also edible.

Fruit Garden at Hakgala.—Mr. Nock reports:—

The beds for the fruit trees were completed in January, and the plants set out 6 ft. apart. They commenced to grow at once, and the cherries and raspberries bore a good many fruit. The apples, pears, plums, cherries, and peaches made very fair growth, and the wood ripened well. They began to rest in June. The strong winds at this time blew off nearly all the leaves, and they had a very rough time of it. Early in November all were pruned that required it, and it was hoped that they would then start into active growth, and to induce them to do so they were lightly syringed night and morning. Nearly all the apples and a few of the pears and plums started into growth in December, but I regret to have to report that none of them look really healthy, and I am afraid that very few are likely to do much good.

Trial of Potatoes at Hakgala.—Mr. Nock, having received from England tubers of twenty varieties of potatoes, has been able to make a trial of them, and gives the results as follows:—

They were planted, in good soil, on February 6 in a plot of ground facing the east. They began to show on the 15th; by the 20th were all above ground, and by the end of the month most of them were earthed up.

During the first three or four weeks they suffered a good bit from grub, especially Nos. 2, 8, 10, 15, 18, and 19. They grew very fast, and looked remarkably well till the heavy rains at the end of March, and immediately after the rains some of them began to show signs of disease in the tops, the worst being the Kidney varieties, Nos. 5, 9, 13, 15, and 19.

The weather continuing wet they were all lifted on April 22, having been in the ground only seventy-five days. If the weather had been fine they would have been allowed to stay in the ground a fortnight or three weeks

longer. The sets were all carefully counted and weighed before they were planted, and the tubers produced were counted and weighed as they were lifted. The following table will show the result :—

No.	Names.	Number of Sets.	Weight in Ounces.	Number bitten off by Grubs.	Number of Tubers produced.	Weight in Ounces.	Remarks.
1	Magnum Bonum ...	15	28	1	250	336	Stood the rains well
2	Vicar of Laleham ...	16	28	6	36	146	Do. and tubers all large
3	White Roses ...	15	22	1	170	336	Do. and tops not much diseased
4	White Elephant ...	15	28	1	86	216	Do. do.
5	Ashleaf ...	8	7	2	30	11	Very badly diseased, and very small
6	Adirondack ...	13	29	—	140	336	In every way satisfactory
7	Weber's Early White Beauty	17	21	1	130	352	Do.
8	Mona's Pride ...	8	8	6	36	32	Suffered from grub, otherwise good
9	Racehorse ...	4	3	—	22	15	Badly diseased
10	Tom Price's Black Prince	9	9	6	24	16	A capital potato, no disease, but badly cut off by grub
11	Reece's Kidney ...	4	4	3	4	1	Suffered from grub
12	Chiswick Favourite.	4	7	—	32	64	Stood the rain the best, and in every way satisfactory
13	Bowyer's Kidney ...	5	6	3	16	16	Badly diseased
14	Imperator ...	10	18	3	80	208	Stood the rains well, a capital potato
15	Premier ...	6	7	6	—	—	Came up weakly, and all were taken by grub
16	Beauty of Hebron...	4	5	—	21	64	Suffered badly in the tops, but a fine potato and of large size
17	Cosmopolitan ...	6	9	2	26	48	Suffered badly in the tops, but fairly good crop
18	Yorkshire Hero ...	5	6	5	6	3	Did no good
19	Myatt's Prolific Ash-leaf	14	21	10	36	24	Suffered most from grub, and produce very small
20	Sutton's Seedling ...	19	25	3	145	240	Suffered badly in the tops, but gave a good round crop

It will be seen from the above that ten or twelve sorts gave capital returns, Weber's Early White Beauty being the best,—producing 22 lb. from 22 oz. There is no doubt that potatoes can be grown very profitably at elevations from 4,000 to 5,500 ft. if they are planted in the dry months, but a week's heavy rain, or even a soaking of 2 or 3 in. of rain, generally brings on disease and puts an end to their growth, and when this occurs the sooner they are lifted the better.

Shantung Cabbage.—Seeds of this Chinese vegetable, the “Pé-tsai,” were received from Kew early in the year. A good account of this cabbage will be found in the Kew Bulletin for May, 1888 (p. 137). It is the *Brassica chinensis*, L., and is considerably different in appearance from the ordinary varieties of cabbage. The seeds were sent to Hakgala, and the following report is now forwarded by Mr. Nock :—

It grows, I find, remarkably well here. In appearance and habit of growth it is like a gigantic Cos lettuce, bright pea green in colour, and when cooked possesses a very agreeable and delicate cabbage flavour. It also has the great advantage of standing the rains well, and growing quickly to a size ready for use. The stalks of the leaves being thick and succulent, can be dressed and eaten like seakale, and taken altogether it may be considered a valuable addition to the kitchen garden.

In China it is also eaten uncooked as a salad, and said to have a very delicate flavour.

Stachys tuberifera, Naud. (*Stachys affinis*, Bunge).—In continuation of last year's report Mr. Nock writes :—

The crop of this vegetable was taken up in September, and weighed 20 lb. This was the produce of a small patch of land 9 ft. long by 4 ft. broad. The soil was literally full of the small edible roots. They are, however, I fear, too small and insipid to meet with much favour among Europeans. The roots were stored in dry sand, but they did not keep well, and a good many very soon decayed. All the sound roots were again planted in December, and commenced to grow at once. We have now a good stock of plants, and can supply any one who wishes to try them.

This vegetable seems to be very popular in France, and at Amiens a preserve is made from it. The English name for it in some catalogues is “Vegetable Whitebait.”

Ullucus tuberosus.—The following further information on this vegetable is sent by Mr. Nock:—

The crop of these tubers was lifted early in the year, and the produce from 30 square feet was 15 pounds, and from another little patch was gathered 9 lb. Reckoning 15 lb. from 30 square feet, they cropped at the rate of 9 tons to the acre. But the whole crop of 24 lb. was taken from a space of 100 square feet, which gave a yield of, say, 5 tons to the acre. This shows a variation, of, say, 4½ tons an acre for a bad crop up to 9 tons for a good crop. Fifty of the largest tubers weighed exactly 20 oz. The 12 largest weighed 6 oz., and the largest single tuber exactly $\frac{3}{4}$ of an oz.

They have very much improved in strength of growth and size of tuber since last year, and I think by selection and careful cultivation there is no reason why they should be produced in a few years as large as ordinary potatoes. And if the flavour can only be improved in a corresponding degree, it would become a valuable vegetable, as it grows well, and so far has not been subject to any disease.

The above anticipations of Mr. Nock have been since confirmed by the results of lifting, on February 26, the crop yielded by 50 selected tubers planted on June 10, and weighing only 17 oz. He writes:—

I found the yield to be 52 lb., and the largest tuber was a little over 2 oz. One root gave 636 tubers, weighing 6 lb.. These were grown in a bed only 32 ft. long by 3 ft. wide; the yield per acre would be enormous.

Mr. Nock sent me twelve of the best tubers for trial as a vegetable, and boiled in well salted water until quite tender, and served with white sauce, they are excellent. They are a little "waxy," but I think that in this tuber, if we have not exactly a substitute for the potato, we have a very good addition to our vegetables.

Conifers at Hakgala.—The yield of timber of two trees at Hakgala cut down this year is worth nothing—one, *Cryptomeria japonica*, about sixteen years old, produced 90 ft. of 1-in. boards, measuring in width 16 in. at bottom to 6 in. at top. The other, *Cupressus torulosa*, about twenty years old, gave 176 ft. of 1-in. boards, much like white pine in appearance, and easy to work.

Library.—The MS. catalogue of the contents of the Library, which I prepared several years ago, and have since kept up, has now been printed, forming a little pamphlet of 28 pages, which was issued in February. The titles are systematically arranged under thirteen classes of subjects.

The Library contains a good working collection of Botanical books, but their careful collation showed that a good many were imperfect. The most serious gaps were in that most necessary constituent of a Botanic Garden library, the "Botanical Magazine," and these, I am glad to say, we have been able almost to fill up by means of a special vote. This was sufficient to purchase the whole of the first series (53 volumes), and seven volumes of the third series, leaving only eight volumes needed to complete this valuable work, which has now reached its 116th annual volume.

Museum.—During the coming year I hope to make a good commencement with a Museum of Economic Botany at Pérádeniya, a small vote for the purpose, long promised, having at length been granted. This will all be expended on glass-fronted cases and glass-stoppered jars, experience having shown that all dried vegetable specimens must be protected from the air. Four rooms of the house formerly occupied by the Director are available for the Museum, of which two are now occupied by timbers, and I purpose, at all events for the present, to restrict the collection to the wild and cultivated productions of Ceylon only. And I may take this opportunity of appealing to all who have the means of obtaining specimens and samples suitable for exhibition to assist me in making an adequate display of raw and manufactured vegetable products of all kinds, and from all parts of the Island, by forwarding such to Pérádeniya.

COFFEE, TEA, CINCHONA, COCOA, AND CARDAMOM SALES.

No. 12.]

COLOMBO, JUNE 25, 1889.

{ PRICE:—12½ cents each; 3 copies.
30 cents; 6 copies ½ rupee.

COLOMBO SALES OF TEA.

Mr. E. JOHN put up for sale at the Chamber of Commerce Sale-room today, 5th June, the undermentioned lots of Tea (20,194 lb.), which sold as under:—

Lot No.	Mark	Box No.	Packages	Description	Weight per lb.	c.
1	M R	245	1 ch	congou	92	21

A Health-giving, Refreshing, Cooling, Sparkling, and Invigorating Summer Beverage, or for any Season, and a Gentle Laxative and Tonic in the various forms of Indigestion.

ENO'S "FRUIT SALT"

Invaluable to Residents in
HOT COUNTRIES.

Is the best Preventive and Cure for

Biliousness.	Sick Headache.
Mental Depression.	Want of Appetite.
Skin Eruptions.	Pimples on the Face.
Constipation.	Vomiting.
Giddiness.	Feverishness.
Thirst, &c.	Unnatural Excitement.
Impure Blood.	Errors in Diet.

Instead of being lowering to the system, ENO'S "FRUIT SALT" is in the highest degree Invigorating, and does not cake or get hard in warm and humid Climates. Its effect in relieving thirst, giving tone to the system, and aiding digestion, is MOST STRIKING.

TO AVOID INJURIOUS EFFECTS OF STIMULANTS.

—Experience shows that porter, mild ales, port wine, sweet champagne, dark sheries, liqueurs, and brandies are all very apt to disagree; while light wines and gin or whisky, largely diluted with soda-water, will be found the least objectionable. ENO'S "FRUIT SALT" is particularly adapted for any constitutional weakness of the liver; it possesses the power of reparation when digestion has been disturbed or lost.

PRESERVING AND RESTORING HEALTH.—ENO'S "FRUIT SALT" has a natural action on the organs of digestion, absorption, circulation, respiration, secretion, and excretion, and removes all impurities, thus preserving and restoring health.

CAUTION.—*Legal Rights are protected in every civilised country. Examine each bottle and see that the Capsule is marked ENO'S "FRUIT SALT."* Without it you have been imposed on by a **WORTHLESS IMITATION.** Sold by all Chemists, &c. Prepared only at

ENO'S "FRUIT SALT" WORKS, Pomeroy St., London, S.E., by J. C. ENO'S Patent.

CURE FOR SLUGGISH ACTION OF LIVER

ENO'S "VEGETABLE MOTO" is mild, effective, and agreeable, and lasting without force or strain in indigestion, biliousness, sick headache, gout, rheumatism, female ailments, suppressed secretions, head affections, nervousness, sleeplessness from liver derangement, flatulence, wind on the stomach. As a laxative, stomachic, blood, brain, nerve, bile, or liver tonic pill it will be found invaluable for creating and sustaining a natural action of the stomach and biliary secretions.

ENO'S "VEGETABLE MOTO" (or Moto Pill). Sold by all Chemists. Prepared only at

ENO'S "FRUIT SALT" WORKS, Pomeroy Street, New Cross Road, London, S.E.

FAGGED, WEARY & WORN OUT!!

Anyone whose duties require them to undergo mental or unnatural excitement or strain should use

ENO'S "FRUIT SALT."

It allays nervous excitement, depression, and restores the nervous system to its proper condition (by natural means). It is the best preventive and cure for biliousness, sick headache, skin eruptions, impure blood, pimples on the face, giddiness, feverishness, mental depression, want of appetite, sourness of the stomach, heartburn, accidental indigestion, constipation, vomiting, thirst, &c., and to remove the effects of errors of eating and drinking.

STIMULANTS and insufficient amount of exercise frequently derange the liver. ENO'S "FRUIT SALT" is peculiarly adapted for any constitutional weakness of the liver. A world of woe is avoided by those who keep and use ENO'S "FRUIT SALT."

"**THOUSANDS OF MILES IN INDIA.**"—ENO'S "FRUIT SALT" I have found for many years of the utmost value in the hot and dry seasons, also in the monsoons. I have travelled some thousands of miles in India during the last thirteen years, and in all the various changes of climate I have always found ENO'S "FRUIT SALT" the most refreshing beverage I could get, especially after long heavy marches and other fatiguing duties to which the British soldier of late has been exposed to. I am yours, &c., A. Warder, at Central Military Prison, Poonah. Bombay, Jan. 30, 1884. To Mr. J. C. Eno.

CAUTION.—*Legal Rights are protected in every civilised country. Examine each bottle and see that the Capsule is marked ENO'S "FRUIT SALT."* Without it you have been imposed on by a **WORTHLESS IMITATION.** Sold by all Chemists, &c. Prepared only at ENO'S "FRUIT SALT" WORKS, Pomeroy St., London, S.E., by J. C. ENO'S Patent.

BLOOD, BRAIN, NERVE ^{OR} LIVER TONIC

ENO'S "VEGETABLE MOTO" in indigestion, biliousness, sick headache, giddiness, gout, rheumatism, female ailments, suppressed secretions, &c., head affections, nervousness, sleeplessness from liver derangement, flatulence, wind on the stomach, coughs and colds, will be found everything you could wish for, creating and sustaining a natural action of the stomach, bowels, and biliary secretions, &c., and (when necessary) in conjunction with ENO'S "FRUIT SALT" is invaluable.

ENO'S "VEGETABLE MOTO" (or Moto Pill). Sold by all Chemists, etc. Prepared only at

ENO'S "FRUIT SALT" WORKS, Pomeroy Street, New Cross Road, London, S.E.

Analysis Guaranteed.
